"The local effect of arſenic is that of producing ſo violent a degree of inflammation in the part to which it is applied, that mortification enſues. When applied to the ſtomach, indeed, it deſtroys the patient before mortification abſolutely takes place; and the apparent effects of inflammation upon the part, are not ſuch as would deſtroy life, were they produced by any other cauſe. It is to be preſumed therefore that the arſenic, taken internally, kills by being abſorbed, and producing effects in the circulation incompatible with life. Several inſtances of patients dying from the effects of arſenic upon the internal coat of the ſtomach have come under my obſervation, and ſpecimens of its local effects are preſerved among the morbid preparations in the Hunterian Muſeum.

"Corroſive ſublimate appears to act both locally and conſtitutionally, as well as arſenic. Its local effects are however leſs powerful, deſtroying parts to a leſs extent, and the conſtitutional effects from abſorption are more like thoſe common to the different preparations of mercury than to thoſe of arſenic.

"The actual cautery is at preſent almoſt entirely diſuſed in ſurgery, except in caſes of diſeaſed bones, where it is employed to produce death in the part affected, and in that way, put an end to the diſeaſe. It is a much milder application than either of the above, gives leſs pain while acting locally, and produces no conſtitutional diſturbance; and where it is neceſſary to keep at bay a fungous excreſcence, whoſe growth is not very luxuriant, I ſhould prefer it to the others, from a belief that it does not in the ſame degree hurry on the diſeaſed action of the tumour. In caſes of fungous tumours in the mouth, it is the only means that can be employed; and in an inſtance of that kind, the diſeaſe was kept under for ſeven or eight months, by its occaſional uſe, without much pain being produced, or the diſeaſe being at all advanced in conſequence of the application.

"This account of the effects of cauſtic applications is given in this place, to ſhew in what they differ from the operation by the knife; and when compared with it, what are the diſadvantages, in caſes of cancer; although in other tumours, of a leſs malignant nature, they may be employed with ſucceſs."

### *Deſiderata relating to Cancer and Scirrhus.*

The following inquiries were ſuggeſted by the peruſal of a paper which was printed and diſtributed in the year 1803, by the medical committee of an inſtitution ſet on foot for the relief of perſons afflicted with cancer. The writer of this article, however, has not thought it neceſſary to confine himſelf exactly to the plan which is preſcribed in that paper; but has conſiderably increaſed the number of *queries*, with a view to ſhew readers in general how many difficulties exiſt on a ſubject which certain impoſtors and credulous perſons affect to thoroughly underſtand.

*Query* 1. Is there any peculiar habit of body, or mode of living, in either ſex, which diſpoſes perſons to the formation of cancer, or which enables them to reſiſt its influence?

2. It is well known that at certain periods of life, eſpecially in females, this diſeaſe is frequent in its appearance: on what phyſical cauſes does that liability depend?

3. Are there any means by which the actual formation of a cancer might be prevented, in families where this diſeaſe has ſeemed to be hereditary?

4. Do perſons ever ſuffer in their childhood, or before the time of puberty, from ſpontaneous attacks of cancer?

5. Does a child become cancerous by ſucking a cancerous woman; or could this diſeaſe be produced by transferring the virus from one ſubject to another, in a way of accidental inoculation?

6. Are there any parts of the body exempted from ever aſſuming this diſeaſe; and why do certain organs more frequently become affected than others?

7. Is it clear that the diſeaſe called cancer in ſome brute creatures exactly reſembles this complaint in human beings?

8. Has climate or local ſituation any influence in rendering the human conſtitution more or leſs ſuſceptible of cancer?

9. Do the cancers which ariſe in conſequence of particular employments (as chimney-ſweeping) at all differ in their nature from thoſe which affect perſons under diſſimilar circumſtances?

10. How many kinds or diverſities of cancer are there; and do they all, in their ſeveral ſtages, properly come under the ſame generic appellation?

11. Is there any well marked affinity or relation between cancer and other diſeaſes, in their origin, progreſs, termination, or difficulty of cure?

12. What are the ſpecific differences between ſcirrhus, carcinoma, lupus, noli me tangere, fungus hæmatodes, elephantiaſis, and ſyphilis?

13. Does the exiſtence of a cancer in any one part of the body afford a preſumption that there is a cancerous diatheſis, or tendency to a ſimilar morbid alteration of other parts, in the ſame ſubject?

14. May cancer be regarded at any period of its duration, or under any circumſtances, merely as a local diſorder; i. e. limited to the ſpot which is viſibly affected, and not neceſſarily contaminating (although tending to contaminate) other organs?

15. Has it been incontrovertibly decided, whether external injuries give riſe to cancer in any other way than by rouſing to action a diſeaſe virtually exiſting, or at leaſt which was prediſpoſed to make its appearance?

16. Does this inherent diſpoſition or dormant cancerous tendency imply a morbid change capable of detection, and of being rendered quieſcent by artificial preventive meaſures?

17. In what ſenſe may it be admitted that cancer, or the carcinomatous diſpoſition, is ever hereditary? And are there any well authenticated facts to ſupport this notion, in any other ſenſe than as children may inherit the ſame organization or bodily ſtructure which their parents poſſeſſed?

18. Is it certainly known and proved that one particular conſtitution or temperament of body pre-diſpoſes to this diſeaſe?

19. Is the cancerous matter of a volatile and infecting nature, ſo as to generate this diſeaſe in a healthy perſon, (without real contact) by effluvia in the atmoſphere exhaled from a cancerous ſore; or does it only contaminate by direct abſorption of the virus?

20. Can the eſſential form of any other diſeaſe be ſo changed as to aſſume a carcinomatous ſtate, and finally to degenerate into a cancer.

21. Are there any phyſical ſigns, either local or general, by which we can foretel that more obvious morbid change named cancer; or does there neceſſarily occur any viſible alteration of ſtructure in a part, prior to its being abſolutely affected by this diſorder?

22. Has a genuine and confirmed cancer been cured by art, without extirpating or deſtroying the morbid maſs?

23. What is the ſureſt and moſt effectual method of eradicating cancers of every deſcription?

Cancer is a *Surgical* term alſo applied to a ſpecies of bandage for the head, and divided into ſeveral parts, reſembling the legs of a crab-fiſh.

Cancer, in *Zoology*, one of the genera of apterous inſects in the Linnæan ſyſtem. It is alſo a ſubdiviſion or family of the Linnæan Cancri moulded into a diſtinct genus in the Fabrician Entomologia Syſtematica, and other works of that writer, and a genus of cruſtaceous animals diſtinct from inſects with Cuvier, La Marck, Latreille, Boſc, and others.

Under the generic title of cancer, Linnæus compriſes all the ſpecies of crabs, lobſters, ſhrimps, hermit or paraſitic crabs, and in a word every animal of the true cruſtaceous kind that appears to have been known to him, with the exception only of the two genera *Monoculus* and *Oniſcus*, both which are ſeparated by him from cancer.

Linnæus was induced to conſider the cancri, and the two laſt-mentioned tribes of cruſtacea, as inſects, principally from the circumſtance of their being furniſhed with antennæ, poſſeſſing articulated limbs or legs, and having the body covered with a ſolid cruſt. Being deſtitute of wings theſe are referred to the laſt order of inſects *Aptera*, where they follow the genus Scorpio, and precede the two analogous tribes Monoculus and Oniſcus. That Linnæus was not ſtrictly correct in placing the cancri with inſects, even according to his own definition of the inſect tribe, is evident, but the objections ſo far as they regarded exterior characters were of little conſequence, and after his ſyſtem had become generally known the cancri were admitted without further inquiry as genuine inſects into every entomological cabinet. The French naturaliſts of the preſent day do not, however, conſider them as inſects; but independent of thoſe there are indeed few who, either from accuſtomed habit, or opinion, founded on the Linnæan method, do not acquieſce in conſidering them as a branch of entomology.

From the earlieſt times, in which mankind appear to have diſcriminated with tolerable preciſion the affinity which natural objects bear to each other, and their relative poſition in the chain of nature, crabs and lobſters were ſuppoſed to belong to the piſcivorous tribes of animals, and not to inſects. But they were inattentive to thoſe minutiæ of character which in the preſent ſtate of ſcience we are compelled to have recourſe to; thoſe animals were inhabitants of the waters, and in their ideas muſt of courſe partake of the nature of fiſhes. The Greeks and Romans entertained this notion; they admitted them as a race of creatures ſtrongly allied to fiſhes, and from being covered with a ſhell as forming an intermediate link between fiſhes and the covered or teſtaceous molluſca, or what is commonly underſtood even at this time amongſt us by the name of ſhell fiſh. In this light only they were viewed by ſucceeding generations even till the time of Linnæus, who in his great reform of the animal kingdom thought it neceſſary to ſeparate them entirely from the covered molluſca, and place them among inſects.

How far Linnæus was right in rejecting the eſtabliſhed though vulgar notions that had prevailed among mankind for ſo many ages, remains to be examined. To a curſory obſerver it muſt appear ſtrange, we had almoſt ſaid unphiloſophical, to be told by thoſe to whom they look up for ſcientific information, that crabs and lobſters belong to the ſame claſs of animated beings as beetles, moths, and butterflies. But we are not to be governed by prejudices, nor by the veneration we are too apt to entertain for the knowledge of paſt ages in thoſe matters where our own judgment may be employed with equal or greater certainty; they may really have a natural affinity to each other without being obviouſly ſo in their external characters. Cetaceous animals are called fiſhes by the bulk of mankind, though the naturaliſt is fully ſatisfied they have ſcarcely any other relation to fiſhes than exterior figure, and living in the ſame element. The opinion alſo that crabs and lobſters are inſects, as Linnæus deſcribes them, is ſanctioned by the authority of ſo many writers of ability that we cannot be too cautious in venturing to diſcountenance an opinion ſo well ſupported. It is a matter of diſcuſſion that claims the moſt mature deliberation of the naturaliſt, and fortunately one that has undergone inveſtigation by men well qualified for the taſk, or it would be impoſſible to do it juſtice within the limits of our preſent article. The leading particulars may be explained; and if from the reſult of theſe it ſhould appear that the cruſtacea ought really to be ſeparated from inſects, neither the opinion, nor the example of Linnæus, or his admirers, ſhould deter us from moving them to a more applicable ſtation in the ſcale of zoology. The queſtion is plain, and reſolves itſelf to this point. Is Linnæus correct or not in placing the cancri among inſects? and if he is wrong in this reſpect, not the cancri alone, but the monoculi, and other true cruſtacea, muſt be referred, as well as the cancer genus, to ſome new order or tribe perfectly diſtinct from and independent of entomology.

Were it not for the following characters which the cruſtacea poſſeſs in common with inſects, there are circumſtances attending them that might at once forbid us to place them where Linnæus has. Like inſects they are furniſhed with antennæ, and with limbs divided into joints, and in theſe eſſential particulars approach ſo near the apterous order of inſects, that it would ſeem almoſt as conſiſtent to expunge the whole apterous order from the ſyſtem of entomology as to deprive it of the genus cancer. Theſe reaſons have weight with many, and among others with Fabricius. This writer, to whoſe entomological knowledge we ought not to deny conſiderable praiſe, is a tower of ſtrength on the Linnæan ſide of the queſtion; for like Linnæus he admits the cruſtacea as inſects, although he invariably rejects the Linnæan mode of claſſing them; however therefore he may diſſent from Linnæus in ſyſtematic arrangement, he affords him countenance in the moſt material point under immediate conſideration; namely that the cruſtacea, and of courſe the cancri, are genuine inſects.—But the arguments on the other ſide are alſo ſtrong, and in the minds of ſome may be equally convincing.

It is worthy of remark that our countryman Pennant, a writer, whoſe knowledge of entomology was confeſſedly limited, ſhould be the firſt among modern writers who preſumed to divide the crabs, lobſters, and marine oniſci from the inſect tribes, after the Linnæan Syſtema Naturæ had been generally adopted throughout Europe, and that without having any other motive than a deſire to include thoſe cruſtacea in his Britiſh Zoology. He had but a ſmall acquaintance, as he himſelf expreſſes it, with inſects, and therefore took the liberty of ſeparating the cruſtacea from inſects that he might treat of the former alone. (vid. pref. v. 4. Brit. Zool.) Mr. Pennant was not at that time aware that future naturaliſts might accede to ſuch a ſeparation as he had ſtruck out by accident, from a conviction of its being both natural and juſt; but this has ultimately proved to be the caſe at leaſt to a certain extent.

The idea of cruſtaceous animals being inſects prevailed among the continental naturaliſts from the time of Linnæus till very lately. Cuvier was perhaps the firſt who attended with deciſive accuracy to the internal organizations of thoſe creatures, if we except Zoeſel, whoſe inveſtigations, though laborious, were not well directed. (vid. Inſecten-Beluſtigung, &c.) The reſult of thoſe anatomical obſervations made on them by Cuvier are intereſting. They go far to demonſtrate, or rather they effectually prove, that the cruſtacea, and inſects are perfectly diſtinct from each other. Linnæus, it need be ſcarcely repeated, ſeparated the cetaceous animals, ſuch as whales, porpoiſes, &c. from the fiſh tribe, where they had been previouſly placed by authors, and to which they are ſo cloſely allied in figure and habit, becauſe their internal organization did not accord with that of fiſhes. He proved from the reſult of anatomical obſervations, that notwithſtanding their external form they are of the mammalia tribe, having a heart with two auricles, and two ventricles, blood warm, and lactiferous teats, and for theſe reaſons refers them to the ſame order as man and quadrupeds whoſe internal organization correſponds. The ſame arguments will bear good in this inſtance, and if the remarks of Cuvier are correct, crabs, and various other cruſtacea are certainly not inſects. Cuvier found the interior organization of cruſtaceous animals to be very different from that of inſects. In his "Leçons d'Anatomie Comparée," he affirms that cruſtaceous animals breath and reſpire by means of gills in the ſame manner as molluſca, whereas in inſects the organs of reſpiration are aſcertained from the experiments of Reaumur, Swammerdam, and Malpighi, to be diſtributed along both ſides of the body; the ſmall lateral ſpiracles, which we ſee one on each ſide every annulation of the body of an inſect being the openings, through which the air is received into the tracheal organs; and no ſuch ſpiracles are found on the ſides of cruſtaceous animals. Cuvier likewiſe found that the heart of cruſtaceous animals reſembled that of the molluſca, being muſcular, and furniſhed with veſſels for the circulation of fluids. La Marck in his "Syſtême des animaux ſans invertèbres," follows Cuvier in a ſimilar train of obſervation, and mentions alſo, that although inſects undergo one or more changes, during which they ſeveral times caſt their ſkin, this never happens after the inſect has aſſumed its laſt or perfect form (his *arachnides*, ſome of the Linnæan inſects of the apterous kinds excepted.) Crabs and other cruſtacea, he remarks, do not undergo any ſuch metamorphoſe as inſects; their ſkin or ſhell is of a different nature, being half calcareous, and is renewed at ſtated periods, or annually, the old one being thrown off and another growing in its place. Inſects, it is further obſerved, neither couple nor engender more than once in their lives, which ſeems to be the fact with all (ſome aptera excepted); but the cruſtacea, on the contrary, breed many times in the courſe of theirs. The cruſtacea, as is particularly noticed by Boſc, have many pairs of jaws, and antennæ moſt commonly in greater number than inſects, the latter having never more or leſs than two, while the others have almoſt conſtantly four; and the antennæ of the cruſtacea are alſo of a very different ſtructure from thoſe of inſects. Theſe are the moſt material peculiarities in which the cruſtacea differ from inſects, and which we cannot but allow in our own mind to be ſufficient to juſtify the removal of the cruſtacea for ever from the tribes of entomology. Firmly as we admire the merits of the great Swediſh naturaliſt, we ſhould not preſume to attempt the overthrow of a part of his ſyſtem ſo conſiderable as that under preſent conſideration upon trivial grounds, but the reaſons againſt it are cogent, perhaps unanſwerable. We have ever been taught by Linnæus himſelf to regard the internal organization of animals, as an eſſential and unerring guide in the natural diſtribution of the tribes of zoology; it is by this ſtandard the merit of his methodical arrangement of this tribe has been appreciated, and it has fallen to the ground.

The cruſtaceous tribes, thus ſeparated from entomology, muſt conſtitute a new and diſtinct order of animals. Some difficulty next ariſes as to the ſtation in the ſyſtem to which they ought to be referred. By placing them as a ſeparate order immediately after inſects, the innovation might create the leaſt confuſion; but this is even liable to objection. Cuvier arranges them between the worms and inſects, the worms, in his ſyſtem, contrary to that of Linnæus, occurring firſt. La Marck places them between the molluſca and the *arachnides*, a new claſs, compriſing moſt of the Linnæan *aptera*, (cruſtacea excepted) ſuch as the ſcorpion, pycnognon, ſcolopendræ, and others that have *ſtigmates*, or lateral apertures communicating with the tracheal organs of reſpiration, and which engender many times in the courſe of their lives. Latreille's Tableau Methodique des Cruſtacées is placed between the *annelides* (a claſs of worms,) and the inſects, the latter beginning with the *arachnides* of La Marck. See article CRUSTACEOUS ANIMALS.

To follow the French naturaliſts through the mazes of the various ſyſtems propoſed for the arrangement of the crabs and other cruſtaceous animals, is not within the compaſs of our preſent deſign. Thoſe naturaliſts ſeem only to agree in the one decided point, that *cruſtacées* are not inſects, each having in turn rejected the mode of claſſification adopted by his predeceſſor; ſo that no permanent arrangement has hitherto been formed, or perhaps ever may; and to embrace the whole, ſtill fluctuating even in the unſettled ideas of their own authors, would only tend to create inexplicable confuſion. It will very likely be thought more than ſufficient, by the faſtidious few, that the writer of this article has followed them ſo far. In proceeding further he conceives the propriety of forming a new order, as in the preſent ſtate of things it would be impoſſible to purſue any of thoſe already adopted. That which he propoſes is moulded as nearly as poſſible to the Linnæan method. So far as the plain and ſimple rules of ſubdividing the cancri into families rather than genera, as laid down by Linnæus, could be conveniently adhered to, his example is followed; the principal deviations are in thoſe inſtances where alteration has been rendered neceſſary by the diſcoveries of recent naturaliſts in this tribe of animals, and which are of too much conſequence to be overlooked.

The laſt edition of the Linnæan Syſtema Naturæ compriſes only a ſmall number of the ſpecies of cancer at preſent known: his genus cancer is divided into ſeveral families, in which the whole of his crabs, lobſters, paraſitic crabs, &c. are included. The CANCER genus is thus deſcribed. Legs eight, (rarely ſix, or ten) and two chelate hand-claws, or claws furniſhed with a moveable pincer; feelers ſix, unequal; eyes two, for the moſt part placed on peduncles, elongated, and moveable; mandibles horny and thick; lip triple; tail jointed, and unarmed.—The crabs are ſeparated into two principal ſections, *brachyuri*, crabs with ſhort tails, and *macrouri*, crabs with long tails, both which are again divided into ſeveral families.

The cruſtacea are divided by Fabricius into many genera. The Linnæan cancri form a diſtinct claſs called *agonata*, in the Genera Inſectorum of that writer, and comprehend five genera, namely, cancer, pagurus, ſcyllarus, aſtacus, and gammarus. His agonata claſs, in Entomologia Syſtematica, contains eight genera, crabs, hippa, ſquilla, and galathea being added to the preceding, beſides ſome other families of cruſtaceous animals, as limulus, cymothoa, and monoculus. The ſame author, in a later work than the foregoing Supplementum Ent. Syſt. retains part of the Linnæan cancri together in his new claſs *kleiſtagnatha*, but divides them into many genera, which he names cancer, calappa, ocypode, leucoſia, parthenope, inachus, dromia, dorippe, orithyia, portunus, matuta, hippa, and ſymethis; and in his next claſs *exochnata* includes the remainder of the Linnæan cancri in the genera albunea, ſcyllarus, palinurus, palæmon, alpheus, aſtacus, penæus, crangon, pagurus, galathea, ſquilla, poſydon, and gammarus. La Marck, it is clear, has derived material aſſiſtance from the laſt mentioned work of Fabricius. The ſyſtem he propoſes is very nearly allied to that projected by Fabricius, as will appear on a curſory view of the following ſtatement of La Marck's genera of crabs.

*Cruſtacées pedocles.* * Corps court, ayant une queue nue ſans feuillets, ſans appendices latéraux, et appliquée ſous l'abdomen. *Genera*, crabe, calappe, ocypode, doripe, portune, podophtalme, matute, porcellane, leucoſie, maïa, and arctopſis. * * Corps oblong, ayant une queue alongée, garnie d'appendices ou de feuillets, ou de crochets. *Genera*, albunée, hippe, ranine, ſcyllare, ecreviſſe, pagure, galathée, palinure, crangon, palemon, ſquillæ, branchiopode. And among his *cruſtacées ſeſſiliocles*, * Corps couvert de pièces cruſtacées nombreuſes, are crevette (or gammarus), and chevrolle (caprella).

Latreille, in his Cruſtacées Malacoſtracés, further increaſes the genera of this natural tribe, conſtituting altogether thirty-nine genera of thoſe which Linnæus confines to the ſingle genus cancer.

Several of the above-mentioned recently eſtabliſhed genera we conceive it neceſſary to retain as genera, and others as ſubdiviſions of the cancri family in a more compendious form in the following arrangement.

### CRUSTACEOUS ANIMALS.

### Firſt Order, *Cancri Brachyuri*, Linn.

Head not diſtinct from the thorax; body ſhort, having a naked tail, without lateral appendages, or crochets, and folded under the abdomen.

### Genus CANCER.

Mouth uſually furniſhed with ſix feelers; mandibles thick and horny; eyes two, diſtant, elongated, moveable, and commonly placed on peduncles; antennæ four, ſhort, and filiform, or ſetaceous, the inner pair (or ſometimes both), bifid at the laſt joint; legs eight or ſix, and two chelate claws; body ſomewhat ovate; tail ſhort.

1ſt Section. * *Thorax ſmooth, ſides very entire.*

Species.

GRAPSUS. Front retuſe, deflected, and armed with four; body variegated. Fabr. &c.—This is a native of the Weſt India iſlands, where it is not very common. The colour is whitiſh, variouſly, but moſt elegantly varied with rufous, or red ſpeckled with white, or with minute dottings of red, with a few ſtreaks of the ſame colour on a white ground, the red ſpecklings pervading the whole upper ſurface both of the thorax and legs. The hand-claws are comparatively rather ſmall, rough, and of a red colour, bordered with white; body beneath pale.—Cancer tenuicruſtatus of Herbſt. Cancr. of which he deſcribes and figures a large and ſmall variety (moſt likely the two ſexes), is certainly a variety of the cancer grapſus of Fabricius and Linnæus.

MUTUS. Thorax cheſnut-brown tranſverſely on the anterior margin. Fabr.—A native of the Mediterranean Sea. The poſterior part of the body is truncated; hand-claws ſmooth; arms denticulated beneath.

QUADRATUS. Thorax ſquare; ſides crenated; hand-claws ſcabrous; *Bankſian cabinet.* Fabr.

A native of Jamaica. Size large, exceeding that of cancer ruricola; the front inflected, and entire; eyes placed nearly together, and pedunculated; eye lid beneath crenated; thorax acute at the ſides; hand-claws ſhort; arms toothed at both ſides; hands ſcabrous, with elevated dots; legs hairy; appears allied to the *ocypode* genus.

RURICOLA. Firſt joint of the legs ſpinous; ſecond and third with tufts of hair. Fabr.—Cancer ruricola. Linn.

This is the great land-crab of the Bahama iſlands, the hiſtory of which has been ſo amply detailed by Sloane, Cateſby, Seba, and others, that the following particulars, ſelected chiefly from theſe authorities, may not prove unacceptable. "Theſe animals live not only in a kind of orderly ſociety in their retreats in the mountains, but regularly march once a year down to the ſea ſide, in a body of ſome millions at a time, as they multiply in great numbers. They chooſe the month of April or May to begin their expedition, and then ſally out by thouſands from the ſtumps of hollow trees, which they excavate, from the holes which they dig for themſelves under the ſurface of the earth, clefts of the rocks, and other hiding-places. At that time the whole ground is covered with this band of adventurers; there is no ſetting down one's foot without treading upon them. The ſea is their place of deſtination, and to that they direct their march with the utmoſt preciſion. They never turn to the right or left for any obſtacles that intervene, if they can poſſibly paſs over them, and even if they meet with a houſe they will attempt to ſcale the walls. But though this be the general order of their route, they, upon other occaſions, are obliged to conform to the face of the country, and if it is interſected with rivers they are ſeen to wind along the courſe of the ſtreams, but if only a ſmall rivulet occurs, they force their paſſage acroſs it. The proceſſion ſets forward from the mountains with the regularity of an army under the guidance of an experienced commander. They are ſaid to be commonly divided into three battalions, of which the firſt conſiſts of the ſtrongeſt and boldeſt males, that, like pioneers, march forward to clear the route, and face the greateſt dangers. Theſe are often obliged to halt for want of rain, and to go into the moſt convenient encampment till the weather changes. The main body of the army is compoſed of females, which never leave the mountains till the rain is ſet in for ſome time, and then deſcend in regular order, being formed into columns of fifty paces broad, and three miles deep, and ſo cloſe that they almoſt cover the ground. Three or four days after this, the rear guard follows, a ſtraggling undiſciplined tribe, conſiſting of males and females, but neither ſo robuſt nor ſo vigorous as the former. The night is the chief time of proceeding, but if it rains by day they do not fail to profit by the occaſion; and they continue to move forward in their ſlow uniform manner. When the ſun ſhines and is hot upon the ſurface of the ground, they halt, and wait till the cool of the evening. When they are terrified, they march back in a confuſed diſorderly manner, holding up their nippers. They try to intimidate their enemies by clattering their nippers together, as if it were to threaten thoſe that come to diſturb them. Their diſpoſition is carnivorous, though they moſt commonly ſubſiſt on vegetables; for if any of them by accident are maimed, in ſuch a manner as to be incapable of proceeding, the reſt fall upon and devour it upon the ſpot, and then purſue their journey.

" After a march of ſometimes two, or perhaps three months, in this manner, they arrive at their deſtined ſpot on the ſea-coaſt, and then proceed to caſt their ſpawn. The eggs are as yet within their bodies, and not excluded and retained, as is uſual with animals of this kind, under the tail, for the creature waits for the benefit of ſea-water to facilitate their excluſion. For this purpoſe the crab has no ſooner reached the ſhore than it goes eagerly to the edge of the water, and lets the waves waſh over its body two or three times. This has been thought neceſſary by ſome to ripen the ſpawn in the ovaria, as the crab, appearing ſatisfied with this ſlight bathing, immediately retires, and ſeeks a lodging on the land. After this, they ſay, the ſpawn grows larger, is excluded out of the body, and adheres to the ciliations, or hairs under the tail. This bunch is ſeen as big as an hen's egg, and exactly reſembling the roes of herrings. In this ſtate of pregnancy they once more ſeek the ſhore for the laſt time; and ſhaking off their ſpawn into the water, leave them to the chance of fortune and accident to bring them to maturity. At this time whole ſhoals of hungry fiſhes are at the ſhore in expectation of this annual ſupply; the ſea to a great diſtance ſeems black with them, and about two thirds of the eggs are immediately devoured by thoſe rapacious invaders. The eggs that eſcape are hatched under the ſand; and ſoon after, millions at a time of the little crabs are ſeen quitting the ſhore, and ſlowly travelling up to the mountains. The old ones, however, are not ſo active to return; they have become ſo feeble and lean that they can hardly crawl along, and the fleſh at that time changes its colour. The moſt of them, therefore, are obliged to continue in the flat parts of the country till they recover, making holes in the earth, which they cover at the mouth with leaves and dirt, ſo that no air may enter. There they throw off their old ſhells, which they leave, as it were, quite whole. At that time they are quite naked, and almoſt without motion, for ſix days together, when they become ſo fat as to be delicious food. It is ſaid they have then under their ſtomachs four large white ſtones, which gradually decreaſe in proportion as the ſhell hardens, and when they come to perfection are not to be found. At that time the animal is ſeen ſlowly making its way back; and all this is commonly performed in the ſpace of ſix weeks. This animal, when poſſeſſed of its retreats in the mountains, is impregnable, for only ſubſiſting on vegetables it ſeldom ventures out; and its habitation being in the moſt inacceſſible places, it remains for a great part of the ſeaſon in perfect ſecurity. It is only when impelled by the deſire of bringing forth its young, and when compelled to deſcend into the flat country, that it is taken. At that time the natives wait for their deſcent, in eager expectation, and deſtroy thouſands, but diſregarding their bodies, they only ſeek for the ſmall ſpawn which lies on each ſide of the ſtomach, within the ſhell, of about the thickneſs of a man's thumb. They are much more valuable on their return, after they have caſt their ſhells, for, being covered with a ſkin reſembling ſoft parchment, almoſt every part, except the ſtomach, may be eaten. They are taken in the holes, by feeling for them with an inſtrument; they are ſought after by night, when on their journey, by flambeaux light. The inſtant the animal perceives itſelf attacked, it throws itſelf on its back, and with its claws pinches moſt terribly whatever it happens to faſten upon. But dextrous crab-catchers take them by the hinder legs in ſuch a manner that the nippers cannot touch them, and thus they throw them into their bags. Sometimes alſo they are caught when they take refuge in the bottoms of holes in rocks by the ſea-ſide, by clapping a ſtick to the mouth of the hole, which prevents their getting out: and then ſoon after the tide coming, enters the hole, and the animal is found upon the water retiring, drowned in its retreat.

" Theſe crabs are of various colours, ſome are reddiſh, varied with black, ſome yellowiſh, and others black, inclining to blue. Thoſe of a light colour are eſteemed moſt, and when full in fleſh are well taſted. In ſome of the ſugar iſlands they are eaten without apprehenſion of danger, and form no inconſiderable part of the food of the poor negroes."

PAEDERUS. Thorax oblong, with three teeth in front; eyes large and kidney-ſhaped. Herbſt.

Body ſize of a horſe-bean, yellowiſh, with a ferruginous ſpot in the middle of the thorax.

RESIDUUS. Thorax ſubrotund; front on both ſides emarginate. Herbſt. Muſ. Cæſar Viennenſ.

Body ſize of a ſmall walnut. Colour entirely olivaceous, inclining to fuſcous.

AURANTIUS. Thorax entire at the ſides, and retuſe before; front truncated and emarginated; hand-claws glabrous; legs compreſſed. Herbſt.

Moderately large; general colour duſky orange, or browniſh on the thorax; legs paler and more obſcure, laſt joints furrowed longitudinally.

CORDATUS. Thorax undulated; hand-claws heart-ſhaped below, and muricated. Linn.

A large ſpecies, being ſomewhat larger than the ordinary ſize of our edible, or pound-crab, Cancer pagurus. The prevailing colour of the body teſtaceous brown, inclining to fuſcous; legs pale fuſcous, and ciliated at the edges. Inhabits Surinam.

ORBICULUS. Thorax orbiculate, ſmooth, and flat; beak with three ſhort ſpine-like tubercles. Herbſt. Fabr. &c.

A ſmall ſpecies of crab brought from New Zealand by ſir J. Banks. The ſnout is ſhort and exſerted; thorax ſlightly depreſſed, and ſurrounded with a very entire margin; tail conic; legs ſmooth.

Obſ. Fabr. erroneouſly refers for a figure of it to Herbſt. Cancr. t. 2. 23. that being longicornis, not orbiculus.

LONGICORNIS. Thorax orbiculate, ſmooth, and ſmaller than the hand-claws, ſnout of three obtuſe ſpines; antennæ very long. Linn. &c. Inhabits European ſeas. Found on the coaſt of Angleſea, and Kent. Muſ. Donov. This, like the preceding, is of a diminutive ſize.

CHELATUS. Thorax ovate, ſmooth, leſs than the hand-claws; ſnout ſimple and obtuſe; antennæ very long. Inhabits New Zealand. Muſ. Banks.

This kind has the ſnout inflected and entire; thorax an elevated, acute, and entire margin. Arms large, projecting, and three-ſpined at the tip; hand-claw large, ovate, ſmooth, with incurvated pincers. Antennæ twice the ſize of the body. Poſterior legs filiform, thighs canaliculated.

HEXAPUS. Thorax orbiculate and toothed in front; antennæ longer than the body. Fabr. Linn. &c.

Body rather larger than a pea; hand-claws large; colour pale teſtaceous. Found in European ſeas.

PLATYCHELES. Thorax ſmooth, orbiculate, very entire; hand-claws flat beneath and ciliated; antennæ very long. Herbſt. Penn. &c.

Herbſt deſcribes *Die breitſcheere*, the name by which he calls this crab, as being rare in Europe. His figure is copied from that in Pennant's zoology, upon the authority of which he records it as an Engliſh ſpecies. It occurs chiefly in our country, on the ſouth coaſt of Angleſea. Muſ. Donov.

ANATUM. Thorax ſmooth, globular, crenated, very entire; hand-claws ſhort, pincers two-edged. Herbſt. Die endtenkrabbe.

CANCELLUS. Thorax ſmooth, crenated; margin of the breaſt prominently crenated; hand-claws two-edged; arms crenated. Muſ. Herbſt.

Body roundiſh, about the ſize of a horſe-bean; hand-claws rather long and linear. Colour pale browniſh, dotted with white; claws and legs ſlightly ferruginous.

HISTRIÆ. Thorax ſlightly orbiculate and ſmooth, with two teeth on each ſide; tip between the eyes three-toothed, the middle one largeſt. Scopoli.

SCOPOLINUS. Thorax ſubrotund, ſmooth, ſomewhat convex above; antennæ capillaceous. Herbſt. Nutrix of Scop.

ANTENNATUS. Thorax ſubovate; antennæ three times as long; hand-claws wedge-ſhaped. Forſkael.

PHILAGRUS. Thorax convex, and fifteen-toothed behind. Linn. This inhabits Aſia.

CASSIDEUS. Head ſhielded, emarginated; arms with filiform appendages. Forſter. Gmel.

A native of the Indian Seas. Colour ſubdiaphanous, variegated with ſulphur, orange and green.

TALICUNA. Thorax orbicular and very entire; hand-claws muricated. This crab is four inches in breadth, fuſcous, and becomes red in boiling. Fleſh excellent. Inhabits Chili.

GRANARIUS. Thorax ſubovate, ſmooth, very entire; front cuſpidate; eyes cylindrical. Fabr. Slabber.

A minute ſpecies of moſt extraordinary appearance; hardly larger than a grain of wheat. Thorax ſomewhat ovate, ſnout conſiſting of a thick obtuſe ſpine, having a ſmaller one on each ſide at the baſe; the large tubular or cylindrical eyes are placed behind theſe. General colour pale yellowiſh. Found in the freſh waters of Europe, but rarely.

MINUTUS. Thorax ſmooth, very entire, ſomewhat ſquare, with the edges rather ſharp; legs compreſſed. Linn. Cancer nutrix of Scopoli. Frequent in deep waters.

PUSILLUS. Thorax ſmooth, ſquare, very entire, with a ſingle tooth on the tarſi. Herbſt. &c. Inhabits the North Seas, and is greatly allied to minutus, but is not more than one fourth its ſize, and is therefore extremely ſmall; it is alſo depreſſed and of a pale colour.

** Section. *Thorax ſmooth, and cut at the ſides.*

CORALLINUS. Thorax obovate, one-toothed; front three-lobed. This inhabits India, and exceeds the ordinary ſize of our largeſt Engliſh crab, cancer pagurus. The thorax is of a fine coral red, variegated with a few whitiſh marks, but rather pale towards the poſterior end; legs pale reddiſh; pincers blackiſh.

FLORIDUS. Thorax ſmooth, unequal, ſpotted; margin obtuſely ſerrated; hands creſted. Linn.

Canc. incomparabilis, elegantiſſime pictus. Seba. Inhabits India. The figure in Herbſt. p. 39. pl. 5. repreſents the ſhell of the thorax, which appears to be of a white colour, with many large and ſmall red protuberances.

APANTORA. Thorax ovate, denticulated at the ſides; tail triangular. Molin. Hiſt. Chili.

BISPINOSUS. Thorax ſmooth, and two-ſpined each ſide; front four-toothed; hands muricated, and toothed. Inhabits India. Size moderate; thorax roundiſh; colour dirty brown.

MACULATUS. Thorax with round red ſpots, and one-toothed at the ſides; front three-lobed. A native of Aſia. Seba.

SANGUINEUS. Thorax obſoletely two-toothed on each ſide; front four-lobed; hands black. Inhabits deep waters.

XAIVA. Thorax three-toothed at the ſides; front truncated. Body hemiſpherical, and about two inches and a half broad. Inhabits Chili.

MAENAS. Thorax ſmoothiſh, with five ſerrated teeth at each ſide; front three-lobed; joint next the hands with a ſingle tooth. This is our moſt common crab, the general colour of which is green, variegated with yellow. Inhabits Europe.

QUINQUE-DENTATUS. Thorax ſmoothiſh, with five teeth at each ſide; front four-toothed; joints near the hands ſlightly toothed; tail inflected and narrow. Linn. Muſ. Leſk.

CIMICOIDES. Thorax orbicular, five-toothed each ſide, and truncated before; tail inflected; the third joint longeſt and pointed.

PYGMÆUS. Thorax ſmoothiſh, with five teeth each ſide; front very entire; middle joints of the hands one-toothed.

FASCICULARIS. Anterior part of the thorax tufted with hair; ſides with two teeth. Herbſt. Inhabits the Eaſt Indies.

RUFO-PUNCTATUS. Thorax depreſſed, dotted with rufous; front ſix-toothed, ſides two-toothed; hand-claws and legs ſmooth, dotted with rufous. Herbſt.

General colour rich yellow, with innumerable rufous dots. Rather ſmaller than our common crab, C. mænas.

STRIGOSUS. Thorax ſmooth, ſtreaked tranſverſely on the ſides; behind the eye a ſingle tooth; ſnout deflected, with four tubercles before the tip. Herbſt. &c. Larger than C. rufo-punctatus; prevailing colour brown; hand-claws ſhort; legs long and broad. The claws at the extremity of all the legs appear in the figure by Herbſt, rather cancellate, broad, and ſerrated, or faſciculated at the edges, from which it would ſeem rather to belong to the matuta genus than cancer.

LITTERATUS. Thorax impreſſed with the figure of letter H; ſides three-toothed; claws compreſſed and ciliated. Fabr. &c.

A larger ſpecies than C. grapſus. Prevailing colour brown, darkeſt on the thorax.

PLICATUS. Thorax with an elevated longitudinal diverging plait in the middle; ſides emarginate and dentated; hand-claws and legs ſmooth. Herbſt.

Rather ſmall; general colour pale brown; plaits on the back diverging into ſix rays.

TRISPINOSUS. Thorax unequal, front four-toothed, with three ſpines each ſide; hand-claws inflated, pincers blackiſh. Herbſt.

This is a large ſpecies, the legs expanding about twelve inches; the thorax is nearly quadrangular, and moderate in ſize. Colour pale brown.

Marmarinus. Thorax ſmooth, with a ſingle lateral tooth, white with rufous ſpots; front three lobed; middle one emarginate. Herbſt.

Thorax rufous, elegantly charactered with whitiſh; legs pale yellow; hand-claws with a large rufous ſpot on each joint.

Maculatus. Thorax ſmooth, with a ſingle lateral tooth, yellowiſh with rufous ſpots; front three-lobed, middle one emarginate. Herbſt.

Except in colour, this differs very little from the preceding, and may poſſibly be only a variety of it.

Amphitrite. Thorax tuberculated, with four dilated teeth each ſide; front two-lobed; under ſurface of the hands and pincers fuſcous.

Expands ſeven inches; general colour fine orange faintly ſpotted; legs varied, with indented fuſcous marks. Perhaps a variety of floridus. Muſ. Herbſt.

Daira. Thorax, and upper ſurface of the hand-claws tuberculated; thorax broad, and narrowing anteriorly; ſides crenated with teeth; front with two diſtinct tubercles.

Cancer Daria. Herbſt. Length of the thorax an inch; hand-claws moderate; legs ſhort and ſpinous. Inhabits the Eaſt Indies. Muſ. Donov.

Dodone. Thorax rather unequal; front obtuſe, and two-lobed; ſides compreſſed, ſomewhat emarginate, and toothed; hands and legs carinated; pincers black.

Size of the foregoing; thorax blue above; chelate arms and legs teſtaceous brown.

Metis. Thorax unequal, with ſmooth tubercles; front cleft, with two emarginated lobes; margin with five teeth each ſide. Herbſt.

Smaller than C. dodone; colour pale; legs and arms moderate. Muſ. Donov.

Panope. Thorax convex, granulated; front obtuſe, with granulated margin, and cleft in the middle; ſides four-toothed; pincers of the fore-claws black brown.

Smaller than cancer mænas, and ſomewhat ſimilar in figure; general colour olivaceous; upper ſurface of the hand-claws granulated and red. Herbſt.

Tyche. Thorax unequal, flat, tuberculated with granules; front advanced, obtuſely rounded, and cleft; ſides bidentated with two truncated warts; upper ſurface of the hand-claws tuberculated.

Cancer Tyche. Herbſt. Smaller than the laſt, and of a dirty aſh-colour; the tubercles on the hand-claws orange.

Electra. Thorax unequal, and almoſt flat, tuberculated, and minutely granulated; ſides five-toothed; front four-toothed; hand-claws granulated and dentated; pincers rounded, and blackiſh at the tips. Herbſt.

Petræa. Thorax ſmooth, fuſcous, with yellow ſpots; ſides with a ſingle tooth; front three-lobed. Herbſt.

Pitho. Thorax ſmooth, and very glabrous; ſides with a ſingle tooth; front three-lobed, the middle one emarginate.

Length two inches; colour duſky olive. Herbſt.

Ocyroe. Thorax ſmooth, ſomewhat tuberculated, with fuſcous ocellate dots; ſide with a ſingle tooth; front ſlightly truncated, and furrowed in the middle. Herbſt.

Cymodoce. Thorax flat, depreſſed, nearly ſquare, with a ſingle ſpine on each ſide, ſomewhat truncated in front, and ſix-toothed; inner margin of the arm dentated.

Calypso. Thorax convex, unequal, tuberculated, and granulated; ſides three-toothed; front two-lobed, and granulated; hands granulated, and hiſpid; legs ſetaceous.

Eurynome. Thorax flattiſh, tuberculated, and granulated; four jagged ſpines on each ſide; front with many teeth.

Size moderate, colour reddiſh brown, except on the legs, which are brown faſciated with whitiſh: arms and hands prickly; front of the thorax crenulated, with about thirty teeth. Cancer eurynome. Herbſt.

Polydora. Thorax unequal, ſlightly convex, tuberculated, and warted; hands warted; pincers fuſcous; legs tuberculated with ſpines.

Princeps. Thorax elevated in front; ſides emarginate; diſk ſtreaked tranſverſely with ſeries of ſanguineous dots; legs banded with purple.

About the middle ſize; colour ochræous, dotted, and ſpotted with ſanguineous. Herbſt.

Parvulus. Thorax three-toothed at each ſide, and marked with impreſſed lines above; front entire.

Very ſmall. Inhabits the ſhores of the American iſlands.

Pagurus. Thorax with nine obtuſe plaits at each ſide; pincers of the hand-claw black at the tip.

This inhabits moſt of the rocky ſhores of England, and other countries of Europe, and is ſaid to be in the higheſt perfection for the table about Chriſtmas. The fleſh is much eſteemed, as being more palatable and wholeſome than that of any other kind of crab.

Undecim-Dentatus. Thorax nearly ſmooth, with eleven crenulate teeth at each ſide; proboſcis three-toothed; fingers black at the tip.

A native of America. Thorax rather dilated behind, with crenated or rather ſerrated teeth at each ſide; legs and hand-claws ſomewhat hairy.

Spinifrons. Thorax five-toothed at each ſide; ſecond and third tooth bifid; front and hands many-ſpined. Fabr.

Aeneus. Thorax very rugged, obtuſe, and four-lobed at each ſide.

Inhabits India. The legs are compreſſed, varied with grey and rufous; lip doubled, and dotted with black; thighs with a black ſpot in the middle; hands ſmall.

Ochtodes. Thorax unequal, obtuſely toothed at each ſide; proboſcis bifid; hands warty. Herbſt.

Nearly the ſize of cancer mænas; pale fleſh colour. Thorax with four, five, or ſix obtuſe teeth at each ſide; arms and hands of the fore claw tuberculated.

Lactatus. Thorax with four ſerrated lobes at each ſide; hands ovate and ſmooth. Herbſt.

*** Section. *Thorax hairy, or ſpinous on the back.*

Chabrus. Thorax hairy, ſuborbicular unarmed; hands ovate, and muricated. Linn. Inhabits the Indian Ocean.

Setosus. Hiſpid; thorax obcordate, and tuberculated; ſnout bifid and inflected.

Inhabits Chili. Deſcribed by Molin.

Santolla. Thorax prickly, arched, ſubcoriaceous; hands covered with a pellicle. Molin. Chili.

Cristatus. Thorax prickly; proboſcis projecting, bifid, and creſted; legs prickly. Rumpf.

Germanus. Thorax unequal, with a ſpine on the front, and another above the tail.

Inhabits the German Sea. The body is very minute; front with an ovate plate or lamina between the eyes, terminating in a ſpine; tail round, and conſiſting of five globular joints.

Auritus. Thorax one-ſpined in front, with the back ſulcated and ſoftiſh.

A ſpecies of ſmall ſize that inhabits Iceland. Shell with a ſmall erect ſpine behind the eyes; arms one-ſpined at the baſe and tip; thumb with a ſingle tooth.

Cruentatus. Thorax tuberculated and red; ſnout linear and truncated. Scopoli.

Inhabits the Mediterranean. Body ſpotted with white at the tip; hands oblong, ſmooth, and armed with two teeth, legs warty.

Hepaticus. Thorax ſemicircular, gibbous, and warty; the margin ſerrated. Herbſt. A native of America and India.

Scruposus. Thorax tuberculated and flattiſh; the margin prickly; hands creſted at the inner margin.

Deſcribed by Herbſt as an inhabitant of India.

### Genus Dorippe.

Antennæ four, the exterior ones ſetaceous, interior palpiform; thorax ſomewhat heart ſhaped and wideſt behind; hand-claws two, terminating in pincers; four poſterior legs prehenſile, and uſually folded over the back.

Lanata. Thorax heart-ſhaped, unequal, depreſſed, hairy, and four-toothed in front; tail with ſix teeth at the baſe.

Cancer lanatus, Linn. Cancer quadridens. Fabr. Ent. Syſt. Der. Wollenſchild, Herbſt. Inhabits India.

Facchino. Thorax ſmooth; margin very entire, with eight teeth in front. Der maulaſſe, Herbſt. Pale brown, and twice the ſize of the following.

Mascarone. Thorax ſmooth; margin very entire, with ſix teeth in front. Der maſcarell, Herbſt.

The two laſt mentioned ſpecies have the back of the thorax ſingularly indented with waved lines, that bear the reſemblance of a groteſque human face; colour pale fuſcous.

Frascone. Thorax tuberculated, entire; anterior part lobed and dentated. Herbſt.

Colour browniſh; hand-claws and two poſterior pair of legs hairy; firſt joint of the two anterior pair hairy, the reſt naked.

Astuta. Thorax heart-ſhaped, depreſſed, and hairy; anterior part four-toothed; tail ſmooth. Fabr.

Callida. Thorax heart-ſhaped, depreſſed, naked; front quadridentated; tail carinated. Fabr.

Dromia. Thorax hairy, five-toothed each ſide: four poſterior legs equal.

Dromia Rumphii. Fabr. Suppl. Cancer dromia. Linn. Cancer lanoſus. Rumpf.

Aegagropila. Thorax globular, unarmed, and very hirſute; pincers naked, and dentated within.

Dromia aegagropila. Fabr. Suppl.

Artificiosa. Thorax downy, depreſſed, three-toothed at each ſide; poſterior legs large.

Dromia artificioſa. Fabr. Suppl. Inhabits the Indian Ocean.

Obſ. There is reaſon to apprehend that ſeveral ſpecies of crabs deſcribed on the authority of naturaliſts in the genus cancer belong rather to this genus or family.

### Genus Portunus.

Antennæ four, unequal, ſmall, and jointed; the exterior ones ſetaceous and longeſt, interior palpiform; body large, ſhort, and dentated at the edges. Legs ten, the poſterior pair terminated in an ovate plate, or ſwimmer.

† Diviſion. *Thorax bidentated at each ſide.*

Vigil. Thorax ſmooth; arms ſpinous. This is a native of the Indian Ocean. Size moderate, eyes approximate, and ſituated upon very long peduncles; anterior tooth on the thorax much longer than the poſterior one.

†† Diviſion. *Thorax with four teeth at each ſide.*

Peymea. Thorax depreſſed and flat; front truncated and plaited. A ſmall ſpecies of a pale browniſh colour, thorax tinged with red.

††† Diviſion. *Thorax with five teeth on each ſide.*

Puber. Thorax heart ſhaped, and hairy; hands with a ſingle tooth, and tipped with black.

Cancer Puber, Linn. Larger than cancer grapſus, and inhabits the Mediterranean. Front with three obtuſe crenated teeth; ſhells rugoſe of a brown colour with rufous heir.

Feriatus. Thorax ſmooth; hands ovate, multangular, the ſecond joint of the arms with a ſingle tooth. Inhabits the Indian Sea. Cancer Feriatus Linn.

Depurator. Thorax ſmooth; hands compreſſed at the tip.

Cancer Depurator, Linn. Cancer Ramipes, Barrel.

Lancifer. Thorax ſlightly tuberculated with a ſingle ſpine on each ſide, and four teeth in front; anterior legs lineate.

Diſcovered in the Pacific Ocean. Muſ. Banks. Thorax ovate, with ſix tubercles on the back; hands with ſpinous protuberances, the pincers toothed within; thighs of the firſt ſix legs toothed on the inner margin, the laſt joint but one with a ſharp and long ſpine before the tip, the laſt lanceolate and acute; plate of the poſterior legs roundiſh, obtuſe, and ciliated.

Holsatus. Thorax ſmoothiſh, with five teeth in front between the eyes. Size and form of Depurator. Inhabits European ſeas. Muſ. Daldorff.

Rumphii. Thorax ſmoothiſh, with four tuberculate teeth in front; hand-claws ſmooth. Herbſt.

Lassinassa. Thorax unequal, attenuated behind; front advanced, and three toothed. Herbſt.

Velutinus. Thorax three-lobed in front; velvety; hands granulated; legs velvety and furrowed.

Larger than Cancer mænas; colour brown. Muſ. Donov.

Admete. Thorax flat, with crenated tranſverſe lines, and truncated in front; fourth lateral tooth ſmalleſt. Herbſt.

Half the ſize of Cancer mænas, broad, pale brown; fingers of the hands black at the tip.

†††† Diviſion. *Thorax with ſix teeth on each ſide.*

Crucifer. Thorax ſomewhat ſmooth; with eight teeth in front; laſt of the ſix lateral teeth emarginate.

Found in the Indian ſeas. Size large; frontal teeth obtuſe; colour rufous with a croſs in the middle, and lateral ſtripe white. Muſ. Donov.

Lucifer. Thorax ſomewhat ſmooth; front with eight teeth; fingers rufous and black at the apex. Inhabits the Indian Ocean. Daldorff. Colour rufous or reddiſh with four large white ſpots. Shines by night.

Annulatus. Thorax ſmooth; front with eight teeth; legs annulated with violaceous.

Inhabits the Indian Ocean. Smaller than lucifer, ſmoothiſh, and duſky, hand-claws ſpinous, pincers red, a white band in the middle, end black with white tip. All the legs variegated with violaceous and white. Fabr. &c.

Variegatus. Thorax heart-ſhaped, pubeſcent, back tooth of the thorax large; front with eight teeth; hands ſpinous. Fabr.

Bears a ſtrong reſemblance to the following ſpecies, but is ſmaller; and has the thorax rugoſe, the poſterior ſpine longer, and the fingers white. Both are inhabitants of the Indian ſeas, and deſcribed from Daldorff's Muſeum.

Holosericeus. Thorax heart-ſhaped, pubeſcent, front eight-toothed; hands ſpinous.

Truncatus. Thorax heart-ſhaped, pubeſcent, truncated in front, and eight-toothed.

Nearly allied to the two former, but differs in having the thorax broader, truncated in front and all the teeth ſmaller and more obtuſe.

Fasciatus. Thorax in front eight-toothed; legs banded with purple; pincers ſcarlet. Herbſt.

Callianassa. Thorax ſix-toothed; hands ſpinous, and papillous at the angles. Herbſt. Colour uniform dirty olivaceous brown.

††††† Diviſion. *Thorax with eight teeth on each ſide.*

Menestho. Thorax downy, truncated, and four-toothed in front, poſterior lateral tooth large; arms of the fore-claws ſpinous. Herbſt.

A large ſpecies; thorax above ochraceous brown, legs ſame paler.

†††††† Diviſion. *Thorax with nine teeth on each ſide.*

Tranquebaricus. Thorax ſmooth, with four teeth in front; arm dentated. Fabr.

A native of Tranquebar. This kind is eaten in the Eaſt Indies. The thorax is glabrous. Muſ. Daldorff.

Pelagicus. Thorax ſmooth; poſterior tooth large; hands multangular.

Found among ſea weeds. Degæer. Cancer pelagicus. Linn. Colour pale yellowiſh brown; fore-claws long, firſt joint ſpinous.

Sanguinolentus. Thorax ſmooth; poſterior tooth very large, and three ſanguineous ſpots on the thorax. Herbſt. Der Blutfleck.

Commonly confounded with pelagicus, but certainly a diſtinct ſpecies: it has three red ſpots on the back of the thorax, and one on each hand, by which it may be readily known. Pelagicus is ſmaller, the thorax more rounded; poſterior ſpine ſlender, and outline very diſſimilar.

Defensor. Thorax ſmooth; poſterior tooth ſhort; front four-toothed, middle ones very ſhort.

Cancer defenſor. Fabr. Ent. Syſt. Inhabits the South Seas. Muſ. Banks.

Hastatus. Thorax rugoſe; poſterior tooth large: front four-toothed; teeth equal.

A native of America. Muſ. Pflug. and Muſ. Donov.

Armiger. Thorax ſomewhat ſmooth; poſterior tooth large; front five-lobed; arms dentated on both ſides.

Diſcovered in the South Seas. Muſ. Banks. Cancer armiger. Fabr. Ent. Syſt.

Gladiator. Thorax downy; poſterior tooth large; hands ſpotted with ſanguineous. Daldorff. Inhabits the Aſiatic ſeas.

Reticulatus. Yellow reticulated with green; thorax four-toothed in front; poſterior lateral, tooth very long.

Cancer reticulatus. Herbſt. Above the middle ſize; prevailing colour yellowiſh; fore-claws reticulated reddiſh, fingers red. This is a moſt elegant ſpecies.

Forceps. Thorax ſmooth; poſterior lateral tooth largeſt; fingers very long and filiform. Fabr. &c.

Rather ſmall, and entirely of a pale bluiſh green colour. Herbſt.

Ponticus. Thorax rugoſe; poſterior lateral tooth large; hands filiform, fingers ſhort. Fabr.

Smaller than cancer mænas; colour pale brown. Muſ. Donov.

Cedo-nulli. Thorax ſmooth, punctured; poſterior lateral tooth large; front dentated and emarginate, green with yellow ſpots; hand-claws elongated and multangular. Herbſt.

This appears both in ſize and other particulars ſo nearly allied to portunus reticulatus, that they may be conſidered almoſt as varieties of the ſame ſpecies.

Hastatoides. Thorax downy; poſterior tooth large with a ſingle ſmall tooth each ſide behind. Inhabits the Indian Ocean.

††††††† Diviſion. *Thorax oblong-ovate, with three or more nearly equi-diſtant ſpines along each ſide.*

Mammillaris. Thorax ſomewhat aculeated and obtuſe, with a three-ſpined lobe in front; on each ſide a diſtinct rufous mammillated ſpot. Muſ. Donov.

Fabricius conſtitutes a new genus of this ſpecies in his Suppl. Ent. under the name of orithyia. It is the only ſpecies of this genus known.

* Section. Matuta.

Antennæ commonly four, the inner pair of four joints, with the laſt joint bifid, the two exterior ſhort, and ſcarcely viſible; the hand-claws armed with pincers; all the legs terminating in an ovate plate or ſwimmer.

Victor. Thorax dotted all over, lateral margin ſubdentated, the poſterior tooth very large.

Cancer lunaris, Rumpſius and Herbſt. Inhabits the coaſts of Malabar. General colour yellowiſh. Size larger than C. mænas. Muſ. Donov.

Planipes. Poſterior part of the thorax ſtriated. This inhabits the Indian Sea. Muſ. Daldorff.

### Genus Calappa.

Antennæ four, nearly equal; exterior ones ſetaceous; interior of four joints, the laſt bifid; body ſhort, enlarged behind; margin much dilated, and concealing the legs when folded; legs eight, terminating in claws; hand-claws two, hands compreſſed, and armed with pincers.

Fornicata. Thorax ſmooth, crenulated; poſterior dilated, angles very entire; hands creſted.

Inhabits the American Ocean. Cancer calappa of Linn. and Fabr. Ent. Syſt.

Tuberculata. Thorax tuberculated, and many toothed, poſterior dilated angle with crenated teeth; hands dentated.

Diſcovered in the Pacific Ocean. Muſ. Bank. Cancer tuberculatus, Fabr. Ent. Syſt. The thorax of this ſpecies is gibbous, with many tubercles and two impreſſed lines; ſnout ſhort, obtuſe, and ſomewhat reflected at the margins; legs ſimple, fingers ſtriated, and red at the tip; ſecond joint of the hands tuberculated and acute; hands tuberculated.

Granulata. Thorax ſomewhat ſmooth and crenated; poſterior dilated margin five-toothed; hands creſted.

Cancer granulatus, Linn. Inhabits the Mediterranean. This is a large ſpecies, of a pale yellowiſh, or cream colour, with ſeveral obtuſe roundiſh tubercles, of a reddiſh colour, on the fore part of the thorax, and a few on the under ſide of the hands.

Marmorata. Thorax ſomewhat plaited, with three teeth on each ſide; front crenated and emarginated; arms dilated and toothed at the tip.

Lophos. Thorax ſlightly plaited, and crenated on both ſides; hind-margin dentated, and ſix toothed, the poſterior angles dilated and five-toothed each.

Cancer lophos, Muſ. Herbſt. Inhabits the Eaſt Indies.

Cristata. Thorax ſlightly plaited, and crenated on both ſides; hind-margin with ſeven teeth; dilated poſterior angle with three-teeth; hands creſted and toothed. Inhabits China. Muſ. Donov.

Angustata. Thorax ſmooth, crenated on both ſides with teeth, the poſterior one narrow and ſmooth. Inhabits America. Muſ. Lund.

Gallus. Anterior half of the thorax tuberculated; both ſides crenated and dentated; the poſterior dilated angle ſix-toothed; hands tuberculated above. Herbſt.

### Genus Leucosia.

Two or four antennæ, ſmall, quadriarticulate, and inſerted between the eyes. Body ſuborbicular, more or leſs convex, and generally inflated; tail naked; legs eight, and all furniſhed with claws; hand claws two, terminating in pincers.

### Species.

### Diviſion † *with ovate hands.*

**Scabriuscula.** Thorax depreſſed and ſcabrous, front emarginate.

The body of this ſpecies is ſmall, depreſſed, and rough, with elevated whitiſh dots. This inhabits India.

**Globosa.** Thorax ſlightly crenated; tail with two tubercles at the baſe; arms rough. Fabr. A curious ſpecies, diſcovered on the coaſt of Malabar by Dr. Koenig. Its ſize is ſmall, figure ſomewhat globoſe; arms rough, hands filiform. Herbſt deſcribes it under the name of *Die kugelkrabbe*, Cancer globus.

**Craniolaris.** Ovate, very glabrous, or poliſhed; anterior part projecting, and armed with three teeth; hands two-edged and ſmooth. Linn. Die Hirnſchaalkrabbe, Herbſt.

Body about the ſize of a ſmall walnut, or rather leſs, the colour bluiſh, ſlightly tinged with faint red and purpliſh, the claws are of the ſame colour, except the pincers, which are pink; legs browniſh. This inhabits the ſhores of Malabar. Muſ. Donov.

**Porcellanus.** Thorax very glabrous, or poliſhed, ovate, obtuſe at the anterior part; arms granulated. Fabr. *Die porcellankrabbe*, Cancer porcellaneus, Herbſt.

This ſpecies is about the ſame ſize as the preceding, and ſomewhat reſembles it in form, but has the anterior part obtuſe, and without teeth; the lateral margins of the thorax are granulated; general colour pale brown, with the two extreme joints of the hand-claws bluiſh. Inhabits Tranquebar. Muſ. Donov.

**Pila.** Thorax globoſe, with a ſingle obtuſe elevated tooth in the middle, and the margin crenated with teeth.

Inhabits India. The body is ſmall, globular; front obtuſe; hand-claws ſhort and ſmooth.

**Planeta.** Thorax orbicular and flat; ſides bidentated; front with three teeth.

This is a minute ſpecies, and inhabit Terra del Fuego.

**Urania.** Globoſe, highly poliſhed; anterior part projecting and roundiſh; arms warted, hands ſmooth. Herbſt.

An elegant kind of crab, nearly allied to Cancer craniolaris in figure, but above twice the ſize. The body and hand-claws are olivaceous, with ſome obſcure rufous ſpots: from the tip of the ſnout a broad white ſtripe deſcends nearly to the centre of the thorax, where it ends in a bifid termination. The pincers of the hand-claws, and all the legs are yellow ſpotted with ferruginous.

### Diviſion †† *with filiform hands.*

**Punctata.** Thorax ovate, crenated, and three-toothed behind; fingers unarmed.

Inhabits America. Body large, ovate, and rough, with elevated dots; hand-claws long, filiform, and the arms granulated; hands elongated, fingers unarmed. Muſ. Donov.

**Fugax.** Thorax oblong, three-toothed behind; middle tooth longeſt and recurved; fingers dentated.

Frequently confounded with the preceding ſpecies, but is certainly diſtinct. Muſ. Donov.

**Nucleus.** Thorax orbiculate, with two ſpines behind; arms granulated.

Cancer nucleus, Linn. Inhabits the Mediterranean. Muſ. Donov.

**Septemspinosa.** Thorax with an elongated and very acute ſpine on each ſide; five ſpines behind.

Cancer hytrix, Fabr. Ent. Syſt. Inhabits the Indian Ocean.

**Cylindricus.** Thorax with two furrows; ſides dilated, cylindrical, and ſpinous at the tip.

Inhabits Tranquebar. This is of a ſmall ſize; front obtuſe, and grooved in the middle; thorax with two large grooves, and a tranſverſe one on the fore part, all hairy; ſides of the thorax whitiſh, with red dots, rough, and armed at the tip with a ſtrong acute ſpine; tail whitiſh, and rough, with two longitudinal grooves in the middle; legs and arms very thin. Fabr. &c.

**Erinaceus.** Thorax ovate and very ſpinous; marginal ones longeſt and dentated; arms prickly.

Deſcribed from the cabinet of Spengler, by Fabricius, as an inhabitant of the Indian Sea.

### Genus Ocypode.

Antennæ four (ſometimes two), very ſhort, and unequal; peduncles of the eyes lengthened, inſerted in a central projection of the head, and extending along the front to the lateral angle of the thorax; body almoſt ſquare; legs ten, armed with claws, the anterior pair, or arms, terminated in pincers.

**Ceratophthalma.** Thorax dotted; eyes prominent, and terminated in a ſpine.

Cancer curſor, Linn. Cancer ceratophthalma, Fabr. Ent. Syſt. and Pallas, and Cancer curſor of Herbſt and Gmelin. This is a ſpecies of moderate ſize, being rather larger than Mænas, that inhabits the Mediterranean and Indian ſeas, from whence, about ſun-ſet, it comes up the ſhores, and wanders about the ſtrand, running at intervals with great velocity. The right claw is commonly larger than the other; both are ſcabrous, as alſo are the legs, though only in a ſlight degree. The general colour is brown.

Fabricius ſuppoſes the two ſpecies, Curſor and Uca, of Linnæus, to be both of this kind, the latter being only an accidental variety, in which the thorax is marked with a rude figure, ſomewhat reſembling the letter H.

**Heterochelos.** Thorax granulated; hand of one arm much larger than the other.

Cancer vocans, Linn. Cancer vocans major, Herbſt. O. Heterochelos, La Marck. Inhabits Jamaica, where it conceals itſelf under ſtones, and when caught, emits a kind of cry. Size of our common crab, Cancer Mænas.

Obſ. Herbſt has the figure of another ſpecies nearly allied to the above; in form the ſame, but not above one fourth of the ſize. This he calls Cancer vocans major; perhaps the young, or a variety of the preceding, Cancer minor paluſtris, heterochelos of Plumier. M. S. G.

**Quadrata.** Thorax ſmooth; crenated at the ſides; hands ſcabrous. Inhabits Jamaica. Muſ. Banks. Cancer quadratus, Fabr. Syſt. Ent.

**Rhomboides.** Thorax ſmooth; lateral angle armed with a ſpine in front. Cancer rhomboides, Linn. Das Würfelſchild, Herbſt.

Colour pale browniſh; arms long, and ſhaded with rufous. Muſ. Donov.

**Angulatus.** Thorax ſmooth; oblong, with two ſpines at the anterior part of the lateral angle. Cancer angulatus Linn. Ocypoda biſpinoſa, La Marck. Muſ. Donov.

**Lævis.** Thorax ſmooth, with a ſingle tooth at each ſide; hand-claws very ſmooth, right hand largeſt. Inhabits the Indian Sea. Daldorff. Fabr. Suppl.

**Minuta.** Thorax ſmooth, with a ſingle tooth at each ſide; hand claws very ſmooth and equal. Inhabits the iſle of France. Muſ. Daldorff, Fabr. Suppl.

**Brevis.** Thorax ſhort, plaited, with three teeth at each ſide; hand-claws long. Herbſt. Suppl.

Moderately ſmall, colour in general pale brown. Muſ. Donov.

Vocator. Thorax rugoſe, anterior part ſinuous; right hand very large. Herbſt. Suppl.

Body ſomewhat gibbous at the ſides, and narrowing rather behind; colour of the thorax; left hand-claw, and firſt joints of the legs dark red, the firſt variegated with black; largeſt claw, and extreme joints of the legs pale browniſh. Muſ. Donov.

### Genus Maja.

Antennæ four, the interior ones palpiform, exterior ſetaceous; body oval and ſubconic, much enlarged behind, and narrowing towards a point in front; legs eight, armed with claws; hand-claws terminated in pincers.

### Species.

* Section. Parthenope, Fabr. *Arms of the chelate-claws uſually very large.*

Giraffa. Thorax ſpinous, ſpines ramoſe; hand-claws very long and tuberculated beneath. Inhabits the Eaſt Indies. Muſ. Daldorff.

Longimana. Thorax ſpinous, ſpines ſimple; hand-claws very long and ſmooth beneath.

Cancer longimanus, Linn. A native of Aſiatic ſeas. Muſ. Donov.

Regina. Thorax unequal; margin ſpinous; hand-claws very long, with ſpinous angles. An inhabitant of the Indian ſea.

Horrida. Thorax rugged with prickles and tubercles; hands large, tuberculated, and ſomewhat ovate; tail carious. Inhabits the Aſiatic ocean. Called by *Rumpſius* Rotſkrabbe, Die Schreckliche, Herbſt. Great warty Crab of *Petiver*. Muſ. Donov.

Lar. Thorax unequal, four toothed; margin ſpinous; hand-claws ſmooth. This is a native of the Eaſt Indies. Muſ. Daldorff.

Eriocheles. Thorax aculeated, hands ventricoſe, and ſpinous; fingers tufted with hairs. Cancer Eriocheles of Olivier.

Cancer maja, Linn. Parthenope maja, Fabr. Inhabits the northern parts of Europe, and England. Muſ. Donov. Miſtaken by Pennant for Cancer Horridus. This is a large ſpecies.

Dubia. Thorax ſmooth, three toothed in front; hands compreſſed, and ciliated; poſterior legs very ſhort and dorſal. Inhabits the Indian Sea.

Muricata. Thorax hairy, unequal, with a dorſal line and two dorſal ſpines on each ſide; marginal ſpines four; legs hairy.

Cancer muricatus, Fabr. Ent. Syſt.

Contrarius. Thorax very unequal, tuberculated, and ſpinous, the front projecting and pointed; hand-claws muricated; legs ſimple, and banded with rufous. Herbſt.

Body three inches in length, hand-claws ſix inches long and very large; colour pale brown in general, tips of the pincers of the fore-claws black.

Echinatus. Thorax heart-ſhaped, warted, aculeated; arms and hands of the chelate-claws echinated; legs muricated. Muſ. Donov.

* Section. Inachus. Fabr. *Arms of the chelate-claws uſually ſhort or moderate.*

Hybrida. Thorax hairy, unequal, with a dorſal line, and two dorſal ſpines; marginal ſpines four; legs naked at the tip.

Inachus hyridus. Fabr. Suppl. Very much reſembles the foregoing, but is diſtinct. Inhabits India.

Ovis. Thorax ovate, hairy, with four ſpines each ſide. Cancer ovis Fabr. Ent. Syſt. Inachus Ovis Suppl. Cancer hircus, Herbſt. Inhabits the Eaſt Indies.

Hircus. Thorax woolly, tuberculated; arms muricated; hands ſmooth.

Cancer hircus, Fabr. Syſt. Ent. Inachus hircus, Suppl. Inhabits Jamaica.

Cornuta. Thorax prickly; ſnout with two horn-ſhaped bearded ſpines; hands rounded. Inhabits the Mediterranean ſea. Cancer cornutus, Linn. Inachus cornutus, Fabr. Suppl.

Araneus. Thorax unequal; margin crenated on both ſides; anterior part dilated and acute.

Opilio. Thorax prickly; margin three-toothed behind; hands ſomewhat ſmooth.

In the cabinet of Prof. Vahl. Inhabits the Mediterranean.

Condyliatus. Thorax ovate and prickly; three erect ſpines above the tail; hands muricated.

Size of Cancer Araneus or larger. Thorax unequal, many-ſpined; three large tubercles on the dorſal ſpine behind; thighs armed with a ſpine before the tip. Inhabits the Mediterranean.

Aculeata. Thorax covered with prickles; ſnout long, bifid; five-toothed above, and one beneath. Inhabits the Norway ſeas. Muſ. Vahl.

Chiagra. Thorax tuberculated, unequal; ſnout flat, retuſe; legs tuberculated. Muſ. Donov.

A native of the Mediterranean. Inachus chiagra. Fabr. Suppl.

Angustata. Thorax attenuated in front, and ſmoothiſh; ſnout projecting, bearded, and emarginate at the apex. Inhabits the Eaſt Indies. Body minute; thorax ſmoothiſh with entire margin; legs ſpinous; hand-claws ſhort, hands ſmoothiſh, the reſt ſpinous.

Scorpio. Thorax pubeſcent, with four erect ſpines; anterior legs very long.

Cancer Scorpio, Fabr. Ent. Syſt. Inachus Scorpio, Fabr. Suppl. A native of the European ſeas, chiefly Norway, rarely England. Muſ. Donov.

Phalangium. Thorax pubeſcent, with three acute ſpines on the anterior part, obtuſe tubercles behind; ſnout bifid.

Common in Northern ſeas; frequent on the coaſt of England.

Longirostra. Thorax prickly, projecting, aſcending, ſnout acute and bifid.

Cancer longiroſtris, Fabr. Ent. Syſt. Cancer dodecos, Linn. A native of the Mediterranean and Northern ſeas.

Longipes. Thorax prickly; hands ovate and ſcabrous; poſterior legs very long.

Cancer Longipes, Linn. A native of the Indian Ocean. Rumpf.

Seticornis. Thorax ovate, ſmooth, ſnout very long, and ſerrated on both ſides. Herbſt.

Planissima. Thorax quite flat, and nearly ſquare, with five teeth on each ſide, front trifid with ſpines; inner margin of the thighs, and firſt joint of the hand-claws dentated. Herbſt.

Hirticornis. Thorax heart-ſhaped, unequal, dentated; front with two long, approximate, hirſute ſpines.

Thorax about the ſize of a ſmall walnut; legs moderate, chelate; claws nearly the ſame ſize as the anterior pair of legs, or rather leſs; the whole ſlightly ſpinous, ſomewhat hairy, and of a fuſcous colour. Muſ. Donov.

Dama. Thorax ovate, and granulated, with ſeven ſpines on each ſide; front with two ramoſe ſpines of three branches; arm and joint below the hands of the chelate claws very ſpinous. Herbſt.

Length of the body three inches: legs, and chelate claws moderate; thorax brown; hand claws pale brown; legs blackiſh. Muſ. Donov.

Cornudo. Thorax ovate, unequal, with four ſpines at each ſide; front four-ſpined, the interior pair very long. Herbſt.

From three to four inches long: hand claws filiform, arms four-toothed: thorax paliſh, olivaceous: legs darker. Muſ. Donov.

Squinado. Thorax obovate, unequal, prickly with lateral ſpines; front bifurcated; chelate claws moderate and filiform, arm and joint below the hand prickly; legs unarmed. Muſ. Donov.

Cancer Squinado. Herbſt. Inhabits European ſeas, and is a large ſpecies.

Philyra. Thorax ſubovate, granulated, and unequal; ſnout very large, broad, ſquare, and four-toothed in front; hand-claws ſmall and glabrous. Herbſt.

Rather ſmall, length one inch and a quarter, colour pale, legs faint yellow, ſpotted obſcurely with reddiſh.

Thalia. Thorax ovate and granulated; ſides ſpinous; front truncated, with two acute incurvated ſpines; hand-claws very ſmall.

Length almoſt two inches; prevailing colour ferruginous; hands black or blackiſh.

Cervicornis. Thorax ſomewhat ovate and tuberculated; anterior part much advanced, and armed with four long curved, horn-like ſpines.

Plejone. Thorax conic, tuberculated and ſpinous, with two long ſpines in front; hand-claws and legs unarmed. Herbſt.

This is about an inch and a half in length; thorax pale brown, the two anterior ſpines approximate at the baſe, and curving a little to the ſides upwards; legs pale fuſcous, the firſt pair longer than the chelate claws.

Styx. Thorax ovate, ſubconic, warted, ſnout ſimple, and forked at the apex; anterior pair of legs thick, and hiſpid. Herbſt.

Half the ſize of the former; hand claws very ſmall; colour brown, paleſt on the thorax.

### Crustaceous Animals.

### Second Order. *Cancri Macrouri.* Linn.

Head not diſtinct from the thorax: thorax oblong, with an elongated tail, furniſhed with lateral appendages or crochets.

### Genus Astacus.

Antennæ pedunculated, unequal, the exterior ones long and ſetaceous, inner pair divided at the extremity; body elongated; legs commonly ten; tail foliaceous.

### Species.

Section*. *Inner pair of antennæ two-cleft or bifid.*

Gammarus. Thorax ſmooth; proboſcis toothed at the ſides, with a double tooth on each ſide, at the baſe; hands ſmooth.

Cancer gammarus. Linn. Aſtacus Marinus. Fabr.

This is the common lobſter, a ſpecies frequent in all the northern parts of Europe. It is moſt abundant with us in the northern extremity of Scotland, but is far more frequent than even there on the coaſt of Norway. In a general point of view we can add little to the hiſtory of the lobſter beyond what has been already related by Mr. Pennant, upon the authority principally of Mr. Travis of Scarborough, and of which we ſhall avail ourſelves in this place.

The lobſter inhabits, ſays Mr. Pennant, all the rocky ſhores of our iſland, but chiefly where there is a depth of water. In Llyn in Caernarvonſhire, a certain ſmall lobſter, nothing different, except in ſize, burrows in the ſand. In addition to this we muſt obſerve that the largeſt lobſters we have ever ſeen, ſome few from the coaſt of Scotland excepted, were taken in the lobſter traps within a ſhort diſtance of that part of Caernarvonſhire mentioned by Mr. Pennant, and though ſo very large their flavour was delicious.

Lobſters are brought in vaſt quantities from the Orkney iſlands, and many parts of the eaſtern coaſts of Scotland to the London markets; (but the metropolis is alſo well ſupplied with lobſters at moſt ſeaſons of the year from the coaſt of Norway, and theſe latter are in more eſteem for the table than the Scottiſh kind). Mr. Pennant mentions in his tour in Scotland, in 1772, that ſixty or ſeventy thouſand lobſters are annually brought to London from the neighbourhood of Montroſe alone. Lobſters fear thunder, and are apt to caſt their claws on a great clap; it is ſaid they will do the ſame on the firing of a great gun, and that when men of war meet a lobſter boat, a jocular threat is uſed, that if the maſter does not ſell them good lobſters they will ſalute him. When irritated, or in fear, the lobſters frequently throw off their claws, and the ſame happens commonly when thoſe poor animals are plunged into the boiling-pot for dreſſing. When firſt caught, if taken or entangled only by the claw, they will throw it off with a ſudden jerk, and ſo effect their eſcape.

The habitation of this ſpecies, as Mr. Pennant tells us, is in the cleareſt water, at the foot of rocks that impend over the ſea. This has given opportunity of examining more cloſely into the natural hiſtory of the animal than many others, who live in an element that prohibits moſt of the human reſearches, and limits the inquiries of the moſt inquiſitive. Lobſters are found on moſt of the rocky coaſts of Great Britain. Some are taken by the hand, but the greater quantity in pots, a ſort of trap formed of twigs, and baited with garbage; they are formed like a wire mouſe-trap, ſo that when the lobſters get in, there is no poſſibility of returning. Theſe are faſtened to a cord ſunk into the ſea, and their place marked by a buoy. They begin to breed in the ſpring, and continue breeding moſt part of the ſummer. They are highly prolific. Dr. Baſter ſays he counted 12,444 eggs under the tail of one female, beſides thoſe that remained in the body unprotruded. The eggs they depoſit in the ſand, where they are ſoon hatched. Lobſters change their ſhell annually like other cruſtaceous animals. Previous to their putting off their old one they appear ſickly, languid, and reſtleſs. They totally acquire a new coat in a few days after caſting off the former one. During the time that they remain defenceleſs they ſeek ſome very lonely place, for fear of being attacked and devoured by ſuch of their brethren who are not in the ſame weak ſituation. The circumſtance of the reproduction of the claws in lobſters, though ſurpriſing, is ſufficiently well known: lobſters, as well as crabs, will renew their claws, if by accident they are torn off, within the ſpace of a few weeks after the miſchance has happened. They are very voracious animals, and feed on ſea-weed, garbage, dead bodies, and ſimilar filth.

Mr. Travis communicated ſome intereſting particulars relative to the hiſtory of the lobſter from a variety of obſervations made by himſelf on the coaſt of Scarborough. Lobſters, he obſerves, are found in vaſt numbers, and very fine, upon that coaſt. The larger ones are in general in their beſt ſeaſon from the middle of October till the beginning of May. Many of the ſmall ones, and ſome few of the larger ſort, are good all the ſummer. They are, in general, from four to four inches and a half from the tip of the head to the end of the back ſhell. Commonly the pincers of one of the lobſter's large claws are furniſhed with knobs, and thoſe of the other claw ſerrated; with the former it keeps firm hold of the ſtalks of ſubmarine plants, and with the other it cuts and minces its food very dexterouſly. The knobbed or numb-claw, as the fiſhermen call it, is ſometimes on the right, and ſometimes on the left indifferently. It is more dangerous to be ſeized by them with the cutting claw than the other, but in either caſe the quickeſt way to get diſengaged from the creature is to pluck off its claw: a new one will be produced in its place, though it will never attain the ſize of the former. The female, or hen lobſter, does not caſt her ſhell the ſame year that ſhe depoſits her ova, or in the common phraſe, the berry. When the ova firſt appear under her tail, they are very ſmall and extremely black, but they become in ſucceſſion almoſt as large as ripe elder berries before they are depoſited, and turn of a dark brown colour, eſpecially towards the end of the time of her depoſiting them. They continue full, and depoſiting the ova in conſtant ſucceſſion as long as the black ſubſtance can be found in their body, which, when boiled, turns of a beautiful red colour and is called the coral. Hen lobſters are found in berry at all times of the year. It is a common miſtake that a berried hen is always in perfection for the table. When her berries appear large and browniſh, ſhe will always be found exhauſted, watery, and poor. Though the ova be caſt at all times of the year, they ſeem only to come to life during the warm ſummer months of July and Auguſt. Great numbers of them may then be found under the appearance of *tadpoles* ſwimming about the little pools left by the tides among the rocks, and many alſo under their proper form from half an inch to four inches in length.

In caſting their ſhells, it is hard to conceive how the lobſters are able to draw the fleſh of their large claws out, leaving the ſhell entire, and attached to their body; in which ſtate they are conſtantly found. The fiſhermen ſay the lobſters pine before caſting, till the fleſh of its large claw is no thicker than the quill of a gooſe, which enables it to draw its parts through the joints and narrow paſſage near the trunk. The new ſhell is quite membranous at firſt, but hardens by degrees. Lobſters only grow in ſize while their ſhells are in their ſoft ſtate. They are choſen for the table by their being heavy, in proportion to their ſize; and by the hardneſs of their ſhells on the ſides, which when in perfection will not yield to moderate preſſure. Barnacles and other ſmall ſhell-fiſh adhering to them are eſteemed certain indications of ſuperior goodneſs. Cock lobſters are in general better than the hens in winter: they are diſtinguiſhed by the narrowneſs of their tail, and by their having a ſtrong ſpine upon the centre of each of the tranſverſe proceſſes beneath the tail, which ſupport the four middle plates of the tails. The fiſh of the lobſter's claw is more tender, delicate, and eaſy of digeſtion than that of the tail. The Scarborough fiſhermen do not take lobſters in pots as is uſual in ſtill and deep waters; they uſe a bag-net fixed to an iron hoop, about two feet in diameter, and ſuſpended by three lines like a ſcale. The bait is commonly fiſh-guts tied to the bottom and middle of the net. They can take none in the day-time, except when the water is thick: they are commonly caught in the night, but even then it is not poſſible to take any when the ſea has that luminous appearance which is ſuppoſed to proceed from the nereis noctiluca. In ſummer the lobſters are found near the ſhore, and thence to about ſix fathoms depth of water; and in winter they are ſeldom taken in leſs than twelve or fifteen fathoms. Like inſects, they are much more active and alert in warm weather than in cold. In the water they can run nimbly upon their legs, or ſmall claws, and if alarmed, can ſpring, tail foremoſt, to a ſurpriſing diſtance as ſwift as a bird can fly. The fiſhermen can ſee them paſs about thirty feet, and by the ſwiftneſs of their motions, ſuppoſe they may go much further. Athenæus remarks this circumſtance, and ſays the *incurvated* lobſters *will ſpring with the activity of dolphins*. Their eyes are raiſed upon moveable baſes, which enables them to ſee readily every way. When frightened, they will ſpring from a conſiderable diſtance to their hold in the rock; and, what is not leſs ſurpriſing than true, will throw themſelves into their hold in that manner, through an entrance barely ſufficient for their bodies to paſs; as is frequently ſeen by the people who endeavour to take them at Filey bridge. In froſty weather, if any happen to be found near the ſhore, they are quite torpid and benumbed.

FLUVIATILIS. Thorax ſmooth; ſnout dentated and armed at the baſe with a ſingle tooth on each ſide; hands ſcabrous.

Cancer aſtacus, Linn. The common craw-fiſh of Engliſh writers. This kind ſometimes, though very rarely, attains the ſize of a moderately ſmall lobſter; more commonly they ſcarcely exceed a finger's length. They inhabit rivers, lodging themſelves in holes, which they perforate in clayey banks. Colour olivaceous, or dark brown. Fleſh good. Found in various parts of Europe.

SERRATUS. Hands ſerrated; tail muricated on each ſide by a triple row of ſpinous protuberances. Zool. N. Holl. Inhabits New Holland.

NARVAL. Snout very long, aſcending, compreſſed, and ſerrated on each ſide. Fabr.

A native of the Mediterranean. The tail conſiſts of five leaves, the middle one of which is ſubulate.

CÆMENTARIUS. Thorax ſmooth, cylindrical; ſnout obtuſe; hands aculeated. Molin. Chili.

Very common in the rivers of Chili. Length eight inches; colour fuſcous, veined with red; fleſh white and very good.

CÆRULESCENS. Bluiſh; thorax ſmooth; ſnout advanced, ſubulate, and bidentated. Fabr. Inhabits deep waters. Thorax with two ſmall teeth at the baſe of the proboſcis; firſt ſegment of the abdomen very large; middle leaf of the tail emarginate; legs filiform. Very frequent between the tropics.

FULGENS. Proboſcis very ſhort and ſubulate; legs ſimple. Fabr.

Body ſmall, whitiſh, ſubdiaphanous; ſhines by night. Inhabits the ſea round Braſil.

HOMARI. Segments of the body ſlightly ſpinous on the back; tail faſciculated, and armed with ſerrated ſtyles. Fabr. Found on the coaſt of Norway.

FULVUS. Thorax ſmooth; proboſcis ſhort, ſerrated on both ſides; hands compreſſed, and crenated on each ſide. Fabr.

HARENGUM. Snout ſubulate; eyes globoſe and prominent. Fabr.

This is the principal food of herrings and cod-fiſh, inhabiting the ſeas in prodigious numbers. The body is minute, white, and filiform. Aſtacus halecum of Gmelin.

CRASSICORNIS. Thorax articulated, the ſixth pair of legs very long. Fabr. Inhabits the American ſeas. Thorax carinated on the back, and conſiſting of eight joints; the anterior part retuſe and without proboſcis; tail with ſix filiform ſtyles. Colour reddiſh. Size of the common ſhrimp.

HISTRIO. Thorax armed at the margin with two teeth; ſnout lanceolate, and ſerrated; body variegated. Fabr. Inhabits Greenland. Size ſmall.

PLANATUS. Proboſcis very ſhort and ſubulate; hands very long, with a compreſſed carinated finger. Fabr. Brit. Muſ.

Body ſmooth, pale, and without ſpots; hands flat, above reddiſh, beneath yellowiſh, with a ſingle raiſed line; legs yellowiſh. Size of the common ſhrimp.

BOREAS. Thorax prickly, ſecond and third pair of legs filiform. Fabr. Deſcribed in Phipps's voyage as an inhabitant of the North Sea. The proboſcis is ſhort, depreſſed, acute, grooved on both ſides, with a ſtrong tooth beneath.

CARINATUS. Thorax with a dentated keel; proboſcis ſhort, recurved, and furniſhed with three teeth at the tip. The native place of this ſpecies is unknown.

GROENLANDICUS. Anterior margin of the thorax and proboſcis toothed; feelers ſpinous at the tip; body fuſcous. Inhabits the Greenland ſeas. Snout advanced, with three teeth above and two beneath; exterior pair of antennæ very long, and variegated with red and white; anterior part of the margin of the thorax with three teeth, and back carinated with four; ſegments of the abdomen ending in a ſpine each ſide; middle leaf of the tail with two toothed lines.

VARIUS. Margin of the thorax with a ſingle tooth; proboſcis ſerrated on both ſides; body variegated.

Deſcribed by Fabricius from a ſpecimen taken in the Norway Ocean in the month of Auguſt. The exterior antennæ are longer than the body, rufous with four white ſpots. Thorax cylindrical, ſmooth, with a ſtrong tooth above the eyes. Proboſcis projecting, aſcending, and ſerrated both above and beneath. Abdomen cinereous, with many oblique rufous bands; middle leaf of the tail ſubulate; ſecond pair of legs filiform, and longer than the reſt.

SCABER. Anterior part of the thorax ſcabrous; ſnout ſhort, ſubulate; hands oblong and hairy. Fabr. Inhabits the Indian Ocean. Muſ. Daldorff. Smaller than aſtacus norwegicus.

### Section. ** *Inner pair of antennæ three-cleft.*

JAMAICENSIS. Proboſcis ſerrated above, beneath tridentated; arms and hands muricated, pincers with a ſtrong ſpine on the inner edge. Sloane, &c. Inhabits Jamaica.

NORWEGICUS. Thorax ſpinous on the anterior part; hands priſm-ſhaped, with ſpinous angles. Fabr. Cancer norwegicus. Linn. Found chiefly in the Norway ſea, from whence its name.

PENNACEUS. Thorax ſmooth; proboſcis projecting and ſerrated above, beneath ſmooth; fingers filiform.

This is ſmaller than the laſt. Margin of the thorax with a ſingle tooth each ſide; hands ſhort, ovate with linear acute fingers.

CRANGON. Thorax ſmooth; proboſcis ſhort, and very entire; hands with a ſingle moveable fang. Inhabits moſt ſandy ſhores of Europe. With us is known by the name of ſhrimp. Fleſh delicate. This has only ſix legs; middle leaf of the tail ſubulate; colour pale-yellowiſh, ſemi-tranſparent and dotted.

TETTIGONUS. Thorax ſpinous; four anterior legs filiform. Fabr. Inhabits Iceland.

### *** Family PALÆMON.

Antennæ four; the interior ſhort, trifid, with a ſcale, or plate at the baſe; the exterior very long and ſetaceous; body ſubcylindric; anterior feet terminating commonly in pincers.

CARCINUS. Hand-claws equal, projecting and muricated; proboſcis aſcending, and longer than the antennæ plates. Fabr.—Locuſta marina. Rumpf. Aſtacus fluviatilis major, Sloane. Inhabits rivers of America.

LONGIMANUS. Hand-claws advanced, unequal, ſmooth; ſnout ſtraight, and of the ſame length as the antennæ plates.

Inhabits the Eaſt Indies. The thorax is ſmooth, with two teeth on each ſide at the anterior part; hands filiform, projecting, ſmooth, the left one much longeſt; legs ſmooth.

BREVIMANUS. Hand claws of moderate length; fingers or pincers rather ſhort; proboſcis aſcending, and longer than the antennæ plates.

A native of the Eaſt Indies. *Muſ.* Daldorff.

Smaller than *longimanus*; ſnout compreſſed, and ſerrated on both ſides; thorax ſmooth, glabrous, with two teeth on each ſide of the anterior part; hand-claws filiform, and rather longer than the legs, and ſmooth.

COROMANDELIANUS. Hand-claws of moderate length; pincers rather ſhort; ſnout ſame length as the antennæ plates. From the coaſt of Coromandel. Very ſimilar to the preceding, of which it may be only a variety; it differs principally in the proboſcis, being ſhorter as well as the pincers.

TRANQUEBARICUS. Hand-claws long and filiform; hands ovate. Inhabits Tranquebar. Daldorff.

Snout aſcending, rather longer than the antennæ plates, and ſerrated at the back; hand-claws as long as the body, filiform, very thin and ſmooth; hands thick; legs filiform and ſmooth.

LAR. Hand-claws projecting, equal, muricated; ſnout ſtraight, and length of the antennæ ſcales.

Inhabits India. Fabr. Thorax ſmooth, with two acute teeth on each ſide; ſnout compreſſed and ſerrated; legs muricated.

SERRATUS. Thorax ſmooth and ſubcarinated; ſnout ſerrated on each ſide. Inhabits the Norway Sea. Vahl.

FUCORUM. Thorax ſmooth; ſnout aſcending, with five teeth at the apex. Lives among fuci. Daldorff.

SQUILLA. Thorax ſmooth; proboſcis ſerrated above, and three-toothed beneath; margin of the thorax with five teeth. Fabr.

The prawn. Inhabits European ſeas.

LOCUSTA. Thorax ſmooth; proboſcis projecting, advanced, above ſerrated, beneath ſmooth; pincers elongated and filiform. Aſtacus locuſta. Fabr. Ent. Syſt. Cancer locuſta. Linn.

### **** Family. ALPHEUS.

Antennæ four; the interior ſhort and bifid; exterior long, ſimple, with a ſcale or plate at the firſt joint of the peduncle.

TAMULUS. Hand-claws unequal; the left hand ſmall and filiform. Inhabits the Indian Ocean. Daldorff.

AVARUS. Hand-claws unequal; ſnout ſhort and ſubulate. Inhabits India. Daldorff. The inner pair of antennæ blue; thorax ſmooth; ſnout ſharp-pointed; four hand-claws, the anterior ones largeſt; right hand large and compreſſed; poſterior pair very thin and filiform.

*Obſ.* Tamulus and avarus are perhaps only varieties of the ſame ſpecies.

RAPAX. Hand-claws unequal; anterior part of the thorax carinated; ſnout ſubulate. Daldorff.

A native of the Indian Sea. Thorax ſmooth and glabrous; four hand-claws, the anterior pair of which has ſometimes the right hand, ſometimes the left hand largeſt.

MALABARICUS. Hand-claws unequal; right hand largeſt; legs filiform.

Inhabits the Indian Sea. Left hand longer than the right, (which is largeſt), and filiform.

### Genus Scyllarus.

Antennæ four, unequal; inner pair rather long, filiform, with the laſt joint bifid; exterior ones depreſſed, flat, and dilated, and ciliated with ſpines; thorax large, and uſually aculeated or rough; body long; tail with ſwimming appendages; legs ten; no cheliform arms.

Species.

Arctus. Five ſpines on the anterior part of the thorax; plates of the antennæ ciliated and aculeated.

Cancer arctus. Linn. Potiquiquixe. Jonſt. Umiktak. Müller. Urſa caſtrata. Belon. and Der Bärenkrebs of Herbſt. This is an inhabitant of moſt ſeas. Its ſize is ſuperior to that of the common lobſter. The ſhells are tuberculated, of a brown colour, and ſpotted with yellow; legs ſpotted; thighs ſpinous. Muſ. Donov.

Æquinoctialis. Scabrous; thorax and plates of the antennæ crenated. Brow. Jam. Fabr. &c.

Antarctius. Rough and piloſe; thorax and plates of the antennæ ſerrated and ciliated. A native of India. Fabr. Muſ. Donov.

Orientalis. Scabrous; anterior part of the thorax at each ſide armed with three ſpines; eyes placed cloſe to the foremoſt one. Eaſt Indies. Fabr. Muſ. Donov.

The thorax of this ſpecies, which is of the middle ſize, is rough, with three diſtinct elevated ſpines down the back; colour pale brown.

Australis. Plates of the antennæ roundiſh and ſmooth. Fabr. Muſ. Bankſ.

Diſcovered in the South Seas. Its general figure ſomewhat reſembles arctus, but is narrower; the thorax unequal, with crenated margin; claws ſimple.

### Genus Palinurus.

Antennæ four, unequal, pedunculate; peduncle jointed; interior pair ſhort, ſetaceous, bifid, and unarmed; exterior very long, ſetaceous, and aculeated, or hiſpid; body elongated; legs ten, armed with claws deſtitute of pincers, and tufted with hair at their extremity.

Species.

Homarus. Thorax prickly on the anterior part with two horns in front; arms without hand-claws.—Cancer homarus. Linn. Aſtacus homarus. Fabr. Ent. Syſt. &c. Larger than the common lobſter.

Elephas. Thorax muricate, with four horns on the anterior part; the middle ones larger and toothed.—Palinurus quadricornis. Fabr. Suppl. Aſtacus elephas. Ent. Syſt.

Polyphagus. Thorax very ſlightly ſpinous; legs marbled with blue. Herbſt.

Ornatus. Green, ſides ſpotted with white, abdominal ſegments ſmoothiſh; nearly allied to homarus; ſhorter antennæ, and legs blue, banded with white.

Inhabits the Indian Sea. Fabr. &c. Probably a variety of polyphagus, and not ſufficiently diſtinct from the following ſpecies, which is alſo introduced from Fabricius.

Fasciatus. Greeniſh; abdominal ſegments with a white poſterior band. Muſ. Daldorff. Fabr. A native of the Indian Ocean.

### Genus Galathea.

Antennæ four, unequal and pedunculate; inner ones ſhort, filiform, of three joints, that at the extremity bifid: outer pair ſetaceous and long; body elongated; tail foliaceous; legs uſually ten; arms chelate.

Species.

Strigosa. Thorax plaited on the fore part with ciliated wrinkles; ſnout acute, with ſeven denticles. Fabr. Cancer ſtrigoſus. Linn.

Length from five to ſeven inches when full grown; colour brown; tips of the pincers of the fore-claws red. Inhabits Europe. Muſ. Donov.

Rugosa. Thorax with ciliated wrinkles on the anterior part, and ſpinous; ſnout with three denticles; arms long and ſlender. Galathea rugoſa. Fabr. Cancer rugoſus. Gmel. Cancer bamffius. Penn.

Diſcovered by Mr. Cordiner on the coaſt of Bamff, Scotland. Muſ. Donov.

Gregaria. Thorax with ciliated plates; ſnout with three denticles; anterior feelers very long. Fabr.

Much ſmaller than the two preceding. It is found in the ſea round the coaſt of Patagonia, where it occurs ſometimes in ſuch vaſt ſhoals that the ſea appears perfectly red, that being the prevailing colour of them when alive; it has a brown ſpot on the back; and the hand-claws are rough, Muſ. Bankſ.

Amplectens. Thorax ſmooth; ſnout very ſhort and emarginate; middle pair of legs very long.

The body of this kind is ſmall, whitiſh, ſubdiaphanous, and dotted with red; thorax unarmed, roundiſh behind, and broad, and narrowing towards the front; four antennæ ſetaceous, and very long; abdomen of five ſegments; tail of five leaves, the middle one tongue-ſhaped.

This kind is highly luminous by night; it inhabits the Atlantic, near the coaſt of Braſil. Fabr. Muſ. Bankſ.

### Genus Hippa.

Antennæ ſometimes two, and pedunculate; commonly four, unequal, and fringed with thick hairs; inner pair very ſhort, and bifid; body oblong; tail with ſmall lateral appendages at the joints next the baſe; legs uſually ten, and deſtitute of pincers.

Species.

Adactyla. Thorax ſmooth, with very entire margin; tail inflected, the laſt joint long, ſubulate, and ciliated at each ſide; hand-claw without fangs. Inhabits the South ſeas. Bankſian Cab. Cancer Adactylus, Gmel.

Testudinaria. Thorax ſomewhat ovate, ſmooth, four-toothed in front, ſecond pair of legs longeſt. Herbſt. Muſ.

Eremitus. Tail inflected, laſt joint ovate. Fabr. Inhabits the Indian ſeas. Manibus nullis, pedibus utrinque quinque natatoriis, Linn.

Dorsipes. Thorax glabrous, truncated in front, and armed with ſeven teeth; hand-claws compreſſed, and furniſhed with a falcated thumb. Fabr. Cancer dorſipes, Linn.

This kind inhabits the Indian and Southern Oceans. Length of the body and tail about three inches. Thorax ſmooth, and of a whitiſh colour, the margins hairy and crenated; a ſmall plait ciliated with denticles projects before the front. The outer feelers contain four joints, the firſt and ſecond of which are long, cruſtaceous, compreſſed, and ciliated; tail thin; hand-claws rough above, beneath ſmooth, pincers very ſhort.

Symnista. Thorax truncated and ciliated in front; hand-claws heart-ſhaped. Inhabits India. Cancer ſymniſta of Linnæus.

Scabra. Thorax ovate, truncated before, and armed with many teeth; hand-claws compreſſed, and toothed at each ſide. A native of the South Seas. Muſ. Bankſ.

The thorax of this ſpecies is large, ovate, and rough, with elevated oblong dots, ſides crenated; tail very ſhort, inflected and ciliated; hand-claws incurvated, hands large and rough, with two teeth on the ſuperior margin, and five on the lower one: legs eight, compreſſed, and ciliated, the extreme joint ovate-lanceolate. Fabr. &c.

Dentata. Thorax ſmooth, with five teeth on each ſide; tarſi ſpinous. Fabr. Inhabits European ſeas.

Moderate ſize, gloſſy, pale colour, with a tooth on each ſide, behind the eye, three in the middle, and one behind; arms twice the length of the body, and ſomewhat ſpinous.

Scutellata. Thorax nearly entire and ciliated; hands chelate. Fabr.

Deſcribed by Fabricius, from a ſpecimen in the Britiſh muſeum. Native place unknown. It is ſmall, with ovate thorax, rounded in front, and becoming narrower behind; hands ſmooth.

Gmelin adds to the above ſpecies, Cancharus of Linn. and Sinicus of Herbſt, but expreſſes doubt whether they are of this family or genus.

Cancharus has the thorax rugoſe, oval, hands compreſſed, and ſpinous at the margin. Linn. Inhabits South America and India.

Sinicus. Thorax ſomewhat compreſſed, oval, and ſpinous; arms and legs ſpinous. Herbſt. A native of China.

### * Section Symethis.

Antennæ two, very ſhort, and containing four joints each.

Variolosa. Thorax variolous, and toothed in front; legs furrowed at the tip. Fabr. Ent. Syſt. Inhabits the Indian Ocean.

This ſpecies, arranged in the former works of Fabricius in the genus Hippa, forms a new genus, of which it is the only ſpecies in Supplementum Ent. Syſt. under the name of Symethis, Fabricius having found that inſtead of four antennæ it poſſeſſes only two, and thoſe different in ſtructure from Hippa. His genus Symethis is thus deſcribed: antennæ duæ breviſſimæ, quadriarticiolatæ, intra roſtrum binulæ reconditæ. Perhaps it ought rather to form a new genus than ſection of Hippa, in the preſent arrangement. It is of the middle ſize; ſnout ſhort and ſeven-toothed; anterior part of the thorax with unequal impreſſed dots and obtuſe teeth, ſmooth behind, with lateral rugoſities; hands ſmooth; legs elongated, ciliated, and hooked at the tip. Muſ. Spengler.

Obſ. Fabricius in Supplementum Ent. refers five of the above deſcribed ſpecies to his new genus albunea; ſymniſta, ſcutellata, dorſipes, ſcabra, and dentata.

### Genus Ranina.

Antennæ four, ſhort; the two inner ones bifid at the extreme joint; body oblong, wedge-ſhaped, truncated in front; tail ſmall, and ciliated at the edges; legs eight, the four poſterior ones terminating in ſwimmers; hand-claws two, armed with pincers.

### Species.

Serrata. Cancer raninus, Linn.? Ranina ſerrata, La Marck.

The thorax of this crab is aculeated, or covered with prickles; colour fuſcous; hairs that fringe the legs and tail yellowiſh brown. Inhabits the Indian ſeas. Rumpf. and Herbſt.

### Genus Squilla.

Antennæ four, nearly equal, and pedunculate; interior pair rather long and trifid, the exterior ones with an oblong plate; thorax ſhort; tail very long, and enlarging towards the poſterior extremity; legs fourteen.

### Species.

Maculata. Hands with a ſingle ten-dentated fang; body very ſmooth; tail five-toothed on each ſide. Fabr. Suppl.

Mantis. Hands with a ſingle ſix-dentated fang, ſubangulated; tail ſerrated and ſpinous. Fabr. Suppl. Cancer mantis, Linn.

Inhabits chiefly the Mediterranean and Aſiatic ſeas. I eaten by the Italians and the Chineſe. Length about five or ſix inches.

Raphidea. Hands with a ſingle eight-dentated fang; body with two elevated lines on each ſide.

Very ſimilar to Squilla mantis. Found in the Indian Ocean. Muſ. Daldorff.

Phalangium. Hands with a ſingle five-dentated fang, the firſt and third tooth of which are longeſt; body ſmooth. Inhabits the Eaſt Indian ſeas. Body ſmaller than S. mantis, ſmooth, glabrous; laſt ſegment ſerrated with ſpines. Muſ. Daldorff.

Ichneumon. Hands with a ſingle four-dentated fang; margin of the tail ciliated, with thick ſpinous protuberances. From the Eaſt Indies. Muſ. Daldorff. Smaller than S. phalangium; body with three elevated lines on both ſides.

Scyllarus. Hands with a ſingle ſtraight, ventricoſe, angular, three-toothed fang. Inhabits Aſia. Fabr. Cancer ſcyllarus, Linn.

Ciliata. Hands with a ſingle three-toothed fang; two extreme joints of the abdomen ciliated with ſpines. Inhabits the Indian ſeas. Spengler.

Chiagra. Hands with a ſingle fang, ſubulate, with a rufous protuberance at the baſe. Fabr. Squilla arenaria of Rumphius. This is a native of the South Sea. Muſ. Banks.

Vitrea. Thorax ſmooth, carinated with ſubulate angles; hands with a ſingle ſubulate unarmed fang. Found in the Atlantic Ocean. Muſ. Banks.

### Genus Pagurus.

Antennæ four, unequal, the inner ones ſhort and bifid at the ſummit, the exterior ſetaceous, and uſually longeſt; body oblong, thorax cruſtaceous; abdomen veſicular, naked, ſoft, and furniſhed at the tip with hooks or claws.

The ſpecies of this genus are moſtly paraſitical, and inhabit the empty cavities of turbinated ſhells, the animals of which they attack and devour to gain poſſeſſion of their ſhell, and it is chiefly on the teſtaceous molluſca, or *ſhell fiſh*, that they ſubſiſt. They change their habitation as they increaſe in growth, firſt occupying the ſhells of the common periwinkle, or trochus, then perhaps a nerit as large as a walnut, and after that a whelk. But the paguri of climates warmer than thoſe of Europe are often larger than with us, and require ſhells of conſiderable ſize for their habitation. The tail is naked and tender, being covered only with a ſkin of very delicate texture, but it is furniſhed at the extremity with one or more hooks, by means of which it ſecures itſelf to the ſhell which it makes choice of. It is aſtoniſhing with what facility thoſe animals crawl both in the water and on the ſtrand, bearing at the ſame time the ſhell that ſerves them as a covering on their back. They are indiſcriminately called ſoldier-crabs and hermit-crabs, from the idea of their living in a tent, or retiring into a cell.

### Species.

Latro. Thorax at the ſuture four-cleft; tail ſimple and ventricoſe beneath. Linn. Bouverſires, Rochef. &c. A native of the Eaſt Indies. Inhabits the holes and cavities of rocks, from whence it wanders abroad in the night-time in ſearch of cocoa nuts, which it procures by climbing up the trees, and throwing them down, then deſcending after them, and tearing them open with the two fore-claws.

The Indians eat the fleſh of this kind of hermit-crab after taking out the entrails, which they think poiſonous.

Miles. *Paraſitic.* Left hand largeſt, and muricated on each ſide; legs with very long ſerrated claws. Herbſt. Fabr.

A ſpecies of large ſize. Inhabits the Eaſt Indies.

Custos. *Paraſitic.* Left hand-claw largeſt; hand ſmooth; legs with very long ſmooth claws. Fabr.

A native of the Eaſt Indies, deſcribed in Suppl. Fabr. from the Muſeum of Daldorff; much reſembles *Miles*, but is diſtinct.

Diaphanus. *Paraſitic.* Depreſſed; left hand largeſt and ſmoothiſh; joint below dilated on the back. Inhabits the Indian ſea.

Aniculus. *Paraſitic.* Thorax ovate, ciliated at the ſides; legs rugged, and hairy. Fabr. Deſcribed from the Bankſian cabinet. Inhabits the South Seas.

Bernhardus. *Paraſitic.* Hand-claws muricated, the right one largeſt. Linn. An European kind.

Hungarus. *Paraſitic.* Hands hairy and tipped with black, the right one largeſt, body banded with red. Herbſt.

A native of India. Smaller than Pagurus Diogenes. Peduncle of the eyes pale with red bands; body ſmooth; legs and hands hirſute.

Clypeatus. *Paraſitic.* Thorax ſmooth, very entire and compreſſed; left hand largeſt, and with the legs dotted. Fabr.

Body ſmall, compreſſed, whitiſh. Antennæ fuſcous; hands white, with purple dots, and a marginal blue ſpot. Legs white with innumerable dots and ſpecklings of purple.

Diogenes. *Paraſitic.* Hands muricated, pubeſcent; left hand largeſt. Fabr. Suppl. &c.

Called by Kaempfer, Gami na al Koona, and Modderman of Rumphius. Inhabits American and Indian ſeas. This, like moſt of its genus, inhabits empty ſhells; the general colour is pale teſtaceous or yellowiſh brown.

Tubularis. *Paraſitic.* Subcylindrical: ſhell with excavated dots. Fabr.

Cancer tubularis, Linn. Inhabits the ſhells of Serpula glomerata in the Mediterranean.

Oculatus. *Paraſitic.* Hand-claws muricated, equal; peduncles of the eyes as long as the thorax. Fabr.

Found chiefly in the ſhells of Murex Brandaris. Size of Bernhardus, our common hermit crab. Body entirely ferruginous; peduncles of the eyes advanced or projecting, cylindrical, with a tooth at the baſe. Arms with a ſanguineous ſpot on each ſide; hand-claws rough.

Alatus. *Paraſitic.* Hands ſmooth, with three wing-like projections; right hand largeſt. Fabr. Inhabits Iceland. Dr. Koenig. Rather ſmaller than Bernhardus; joint below the hands rough; wing-like projections acute.

Ophthalmicus. *Paraſitic.* Hands equal, muricated; legs faſciculated with hairs; eyes clavate. Inhabits the Indian Ocean. Daldorff. Eyes large, and placed on ſhort peduncles, at the baſe a ſmall acute ſcale; hands ſhort, equal, muricated, with hairs, rufous. Perhaps Cancer Clibanarius of Herbſt.

Araneiformis. *Paraſitic.* Hands rough; tail callous at the tip, and furniſhed with a hooked tip. Fabr.

Sclopetarius. *Paraſitic.* Thorax ſmooth, entire; hands equal, granulated, thighs of the ſecond pair of legs compreſſed. Herbſt. Der Muſketier.

This is about half the ſize of Pagurus Bernhardus; colour pale brown, with a blue ſtreak down the middle of the two anterior pair of legs, and peduncles of the eyes of the ſame colour.

Tympanista. *Paraſitic.* Thorax ſmooth, very entire; legs ſtriated; claws marbled. Der Trommelſchläger. Herbſt. Smaller than the foregoing; hands linear.

Tibicen. *Paraſitic.* Thorax ſmooth, and very entire; left hand-claw largeſt; hands and legs cheſnut, whitiſh at the tip.

Excavatus. *Paraſitic.* Right hand largeſt, with two excavations, and another ſimilar on the moveable pincer. Der Auſgehöhlte. Herbſt.

Scævola. *Paraſitic.* Hands muricated, left one largeſt, whitiſh; inner ſides bearded; eyes obliquely wedged, pedicle compreſſed. Forſkäl, &c.

Lagopodes. *Paraſitic.* Cinereous brown; legs rough with hirſuties; left hand largeſt. Forſkäl.

Dubius. *Paraſitic.* Hands ſomewhat glabrous; that on the left ſide ſmalleſt. Herbſt. Muſ. Donov.

Canaliculatus. *Paraſitic.* Hands and joint below grooved, with elevated denticulate margin; legs with hairy tufts. Cancer canaliculatus. Herbſt.

Megistos. Rufous with roundiſh white ſpots; hands and legs ſpinous, and hirſute. Herbſt.

A beautiful ſpecies, legs and claws vermilion; thorax paler and body inclining to purple, and ſprinkled all over with diſtinct roundiſh white ſpots; laſt ſegment of the abdomen and baſe of the tail red, but the tail itſelf brown and immaculate. Size of a moderately ſmall lobſter, or rather leſs.

Strigatus. *Paraſitic.* Thorax rather flat, and whitiſh; hands and legs rufous, with tranſverſe ſtreaks. Herbſt. Muſ. Found in a volute. Smaller than Pagurus Bernhardus.

Pedunculatus. *Paraſitic.* Thorax flat, depreſſed; peduncles of the eyes thick; left hand largeſt, inflated, and muricated. Herbſt. Muſ. Donov.

General colour pale ferruginous; abdomen cinereous, marked with pale, yellowiſh at the tip; two poſterior pair of legs pale.

Arrosor. *Paraſitic.* Thorax flat; hands and legs with numerous tranſverſe, irregular furrows. Cancer Arroſor, Herbſt.

### Crustaceous Animals.

Third order, *Cruſtacées ſeſſiliocles, La Marck.*

Heads generally diſtinct from the thorax; eyes fixed and ſeſſile; body long, and covered with many plates.

### Genus Gammarus.

Antennæ four, very ſimple and pedunculate; anterior ones ſhort and ſubulate; poſterior ſetaceous. Head diſtinct, body ſmall, oblong, compreſſed, linear, of many joints. Tail with many ſtyles; legs numerous.

### Species.

Ampulla. Hands without fangs; legs fourteen; poſterior thighs compreſſed and dilated. Inhabits the North Seas. Phipps.

Carinatus. Hands without fangs; legs fourteen; back carinated, and ſpinous. Fabr.

Larger than Gammarus Locuſta; body whitiſh, ſomewhat compreſſed, back carinated; ſegments ſomewhat ſpinous behind. Muſ. Brit.

Nugax. Hands without fangs; legs fourteen; ſix poſterior thighs compreſſed and dilated. Inhabits the North Seas. Phipps Voy.

Cancellus. Hands without fangs; legs ſixteen. Inhabits rivers of Siberia. Oniſcus cancellus of Pallas.

Longicornis. Hands without fangs; antennæ longer than the body; tail obtuſe. Fabr. Cancer groſſipes, Linn. Oniſcus volutator, Pallas. Cancer linearis. Penn.

Locusta. Hands four, without fangs; legs fourteen, thighs ſimple; tail with bifid ſpines. Inhabits ſandy ſhores of Europe.

Pulex. Hands four, without fangs; legs ten. Fabr. Cancer pulex, Linn. Pulex fluviatilis, Ray. Very common in rivers, rivulets, and fountains. Suppoſed to be luminous at times by night. Swims in an incurvated poſture.

Corniger. Hands without fangs; proboſcis incurvated and ſubulate; ſides of the thorax with a double horn. Inhabits the Norway ſeas. The body conſiſts of eleven ſhort ſegments, whitiſh, edged with red.

Linearis. Hands four with a ſingle fang; legs ten. Cancer linearis, Linn. Oniſcus ſcolopendroides, Pallas.

Salinus. Legs twenty, ſpreading; tail ſubulate. Matty.

Stagnalis. Hands without fangs; legs twenty-two; tail cylindrical and bifid. Linn. Tranſ.

Gibbosus. Oblong, gibbous; antennæ folded, and very long. Inhabits Portugal.

Body ſmall, ſmooth, glabrous, yellowiſh ſprinkled with dots of fuſcous. Head thick, obtuſe, with a large green ſpot; eyes large. Antennæ ſetaceous, and bent under the body, folded, and three times the length of the body; tail conſiſting of three acuminated leaves.

Esca. Hands without fangs; tail jointed, ſubulate, and cleft at the tip. Size of Gammarus pulex. Inhabits the Norway Sea, and is the principal food of herrings. Body blackiſh; head ſomewhat hyaline; tail nearly as long as the body.

Medusarum. Hands four with a ſingle fang; head very obtuſe. Inhabits Northern ſeas, and often found adhering to Meduſæ. Ström.

Podurus. Body containing twelve joints; hands four without fangs; legs eight; two laſt joints of the body and the tail ſpinous. Müller.

Mutilus. Arms four, ſecond pair chelate; legs eight; body of ten joints. Müller.

Arenarius. Anterior part flattiſh; poſterior carinated, and ſomewhat ſerrated; four anterior legs cheliform and ſmooth; antennæ nearly equal. Acta Halfn.

Spinicarpus. Four anterior legs cheliform, the joint below the hand produced into an incurvated acute ſpine. Zool. Dan.

Ventricosus. Inflated in the middle, flattiſh, and red; legs fourteen; ſetaceous, the ſecond pair clavate, Müller. Much reſembling the larva of a mantis. Length half an inch.

CANCHARUS, in *Entomology*, a ſpecies of Cancer, (Hippa Fabr.) deſcribed by Linnæus as a native of South America and India, the thorax of which is oval and rugged, with the hand-claws compreſſed, and ſpinous at the margin.

CANCHE, in *Geography*, a river of France, which runs into the ſea, near Etaples, in the department of the Straits of Calais.

CANCHY, a town of France, in the department of the Somme; 5 miles N. of Abbeville.—Alſo, a town in the department of the Calvados; 10 miles W. of Bayeux.

CANCON, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the diſtrict of Villeneuve-d'Agen, 2 leagues W. of Montflanquin. The place contains 1425, and the canton 8506 inhabitants; the territory includes 162½ kiliometres, and 11 communes.

CANCRIFORMIS, in *Entomology*, a ſpecies of Cerambyx, found in South America. The thorax is armed with many teeth; back flat; wing-caſes and anterior ſhanks with a ſingle tooth. Fabricius. Obſ. This is cerambyx puſtulatus of Drury's illuſtrations.

CANCRINE verſes, in *Poetry*, denote the ſame with *retrograde*; which ſee.

CANCRINUS of Rumphius, in *Entomology*, ſynonymous with Cancer cursor. See Cursor.

CANCRIZANS, Lat. Cancrizante, Ital. terms in *Muſic* for a canon, in which one of the parts moves like a crab-fiſh, backwards: as when two parts begin together at different ends of the movement in the ſame melody, paſſing each other till they arrive at the ſeveral ends; then turning back and ending where they began.

CANCROMA, in *Ornithology*, a curious genus of birds, called in England the boat-bill. The ſtructure of its bill is very extraordinary, and has been not inaptly compared to an inverted boat, whence its name; it is alſo gibbous, or ſwollen; noſtrils ſmall, placed in a furrow; tongue ſmall; toes divided.

Two ſpecies only of this genus have been hitherto diſcovered, namely, cochlearia and cancrophaga, which ſee.

CANCROPHAGA, a ſpecies of Cancroma, with a whitiſh belly. This is the cochlearius fuſcus of Briſſ. the tamatia of Maregrave, Ray, &c. and cuillier brune of Buffon.

CANCZUCA, in *Geography*, a town of Poland, in the palatinate of Lemberg; 36 miles W. of Lemberg.

CANDA, a town of Italy, belonging to the ſtate of Venice, in the Poleſin de Rovigno; 14 miles W.S.W. of Rovigno.—Alſo, a river of England, which runs into the Eden at Carliſle.

CANDABORA, in *Ancient Geography*, a town of Spain belonging to the Celtiberians. Ptolemy.

CANDAHAR, or Kandákar, in *Geography*, a country of Aſia, being part of the ancient *Paropamiſus*, and ſituate between the two powerful kingdoms of Hindooſtan and Perſia, became alternately a province of the Mogul empire and of Perſia, till it was again formed into an independent kingdom, as it had formerly been, by Ahmed Shah, one of the Afghan tribe of Abdalli, who, from an obſcure origin, roſe progreſſively in the ſervice of Nadir Shah, or Kuli Khan, to the rank of an Afghan prince. Nadir ſtripped him of his country, and compelled him to join his army in 1739. On the death of Nadir he ſuddenly appeared among his former ſubjects, and in a ſhort time erected for himſelf a conſiderable kingdom in the eaſtern part of Perſia; adding to it moſt of the Indian provinces ceded by the mogul to Nadir Shah. He died about the year 1773, and was ſucceeded by Timur Shah, uſually ſtyled king of Candahar, whoſe ſubjects, in 1783, are ſaid to have lived under an eaſy government, conſidered as an Aſiatic one. At this time the military force of Candahar was eſtimated at 200,000 men. His predeceſſor Ahmed Abdalla had regular infantry, cloathed like the Britiſh ſepoys, and, at one time, made uſe of the Britiſh manufactures for this purpoſe. The trade went by Sindy, and up the Indus and its branches, to Cabul; but it has been long at an end. The ſucceſſor of Timur was Zemaun, whoſe chief ſubjects are Afghans, or the people of the mountains between Perſia and Hindooſtan, who may be conſidered as the founders of the empire; the others are Hindoos, Perſians, and a few Tartars. Candahar is bounded on the north by the Gaur and the province of Balk; on the eaſt by Cabul and the river Indus; on the weſt by Segeſtan, and on the ſouth by Arrhokage, Mekran, Sewee, and Moultan. Beſides Candahar Proper, this empire in its greater extent includes Cabuliſtan, Ghizni, Caſhmire, part of Segeſtan and part of Chioraſan. See Cabul. Every part of it is mountainous except that which lies towards Perſia. The chief city is Candahar.

Candahar, a city of Candahar, the kingdom abovementioned, is aſcribed by M. d'Anville and others to Perſia. While the Perſian and Mogul empires were ſeverally undivided, this was the frontier city and fortreſs of Hindooſtan towards Perſia, and was eſteemed the key of the weſtern provinces of the latter, and not unfrequently changed maſters. As Cabul was conſidered in a political light as the gate of India towards Tartary, Candahar held the ſame rank with regard to Perſia; and hence it has derived its chief importance. Major Rennell has ſhewn that Candahar cannot be the ſame place, as ſome have ſuppoſed, with the Paromiſan Alexandria of Alexander. This city, ſays Forſter, in his "Journey from Bengal to England," compriſed within an ordinary fortification of about three miles in circumference, and of a ſquare form, is populous and flouriſhing; and lying in the great road which connects India with Perſia and Tartary, it has been long a diſtinguiſhed mart. It is abundantly ſupplied with proviſions; the fruits are of an excellent quality; and the extenſive range of ſhops occupied by Hindoo traders atteſts the liberty and protection which they enjoy at Candahar. The tract of territory dependent upon it is ſaid to produce a revenue of 18 lacs of rupees; and from the appearance of all claſſes of people, the collection ſeems to be made without any extraordinary rigour. The environs of Candahar occupy an extenſive plain, covered with fruit gardens and cultivation, and interſperſed with numerous ſtreams of ſo excellent a quality as to become proverbial; and the climate is happily tempered between the heat of India and the cold of Ghizni. To the weſt there is a conſiderable deſert, extending nearly to Herat, which renders the paſſage from Perſia to Hindooſtan difficult. Between the mountains of Hindoo-Kho, and thoſe of Candahar, the country aſſumes the form of an extenſive valley, from Cabul to the borders of Choraſan; and in the tract between Cabul and Candahar, the higheſt point of elevation of the country is marked by the deſcent of the waters from it in almoſt every direction. The diſtance from Candahar by Cabul to Agra is 1208 miles; to Benares, 1588; to Calcutta by Moorſhedabad, 2152; by Birboom, 2047; and to Delhi by Cabul, 1071. N. lat. 33°. E. long. 65° 33′.

CANDAIL, a town of Perſia, in the province of Mekran; 148 miles E. of Kidge.

CANDANA, in *Ancient Geography*, a town of Aſia, in Paphlagonia.

CANDASA, a town of Aſia Minor, in Caria. Polybius.

CANDAU, in *Geography*, a town of the duchy of Courland; 24 miles E. of Goldingen.

CANDAVIA, in *Ancient Geography*, a county of Macedonia, mentioned by Cæſar and alſo by Seneca, which lay at ſome diſtance E. of Dyrrachium. It was bounded towards the eaſt by the Candavian mountains, from which flowed the river Panyaſus. Theſe are ſuppoſed to be the "Cambavii montes" of Livy, and the "Canaluvii montes" of Ptolemy.

CANDE′, in *Geography*, a town of France in the department of the Maine and Loire, and chief place of a canton, in the diſtrict of Segré, ten miles S.W. of Segré. The place contains 948, and the canton 6,343 inhabitants; the territory includes 285 kiliometres and 6 communes.

CANDEISH, a province of the ſouthern part of Hindooſtan, in the territory of the Poonah, or weſtern Mahrattas, being one of the three ſoubahs formed by Acbar in the 16th century out of the conqueſts in the Deccan. It occupies the ſpace between Malwa on the north, Berar on the eaſt, and Amednagur on the weſt and ſouth. Its ſoil is fertile, though mountainous, and it produces more cotton than any other province of Hindooſtan. The revenue of this province under Aurungzebe, as ſtated by Mr. Fraſer in his "Life of Nadir Shah," amounted to 112 lacs of rupees. The principal town is Burhanpour, which ſee.

CANDEL, and Candela, in *Botany*. See Rhizophora.

Candel, in *Geography*, a town of France, in the department of the Lower Rhine, and chief place of a canton in the diſtrict of Wiſſembourg; the place contains 2366, and the canton 13,424 inhabitants; its territorial extent comprehends 187½ kiliometres, and 16 communes.

CANDELA, a town of Naples, in the province of Capitanata; two miles S.W. of Aſcoli.

CANDELABRUM, in *Architecture*. This term, adopted from the Latin, is employed to denote the ſtands or ſupports, in common uſe among the ancients, to place their lamps upon; or which were hollowed out in the upper part, in the form of a braſier or baſon, for the combuſtion of inflammable ſubſtances.

Candelabra are among the elegant and ornamental remains of antiquity, and curious, as they preſerve the remembrance of primitive cuſtoms. The moſt ancient method of illuminating apartments during the night was apparently by burning dry and reſinous wood, either in braſiers, or more ſimply, by ſingle branches like flambeaux: the uſe of oil and of lamps ſucceeded to theſe imperfect and incommodious methods, and candelabra ſerved to ſupport the lamps.

In treating of Candelabra they are to be divided into the two general claſſes already intimated; thoſe which terminate in braſiers conſtitute the firſt, and thoſe which ſerved as lamp ſtands, the ſecond.

In the firſt claſs are comprehended the moſt remarkable for ſize and magnificence; ſome of theſe, which by their deſtination reſemble altars, and may even be confounded with them, were employed in temples and private chapels for burning incenſe. Cicero informs us, that not a houſe in Sicily was without theſe ſacred utenſils, made of ſilver. Candelabra of this kind are not unfrequently found repreſented in baſſo relievos and on the frizes of temples.

Very large marble candelabra are found at Rome, where, as Winckelmann obſerves, not one of bronze has been diſcovered; theſe from their great ſize and elevation correſpond to the vaſt halls of Roman edifices, which they illuminated.

The marble candelabra vary greatly in the ſhape, both of the braſier, and of the body or pillar which ſupports it; and many of them preſent models of taſte, in form, ornament, and execution. The richeſt collection of theſe objects is publiſhed in the *Muſæum Vaticanum:* two among theſe, which were found in the Barberini palace, are diſtinguiſhed as exquiſite ſpecimens of ornamental workmanſhip; the baſe is a triangular altar, having each face ornamented with a figure of a divinity; the ſhaft is compoſed of acanthus leaves diſpoſed in tiers in the ſtyle of a Corinthian capital, ſo that one of theſe candelabra appears, at firſt ſight, a union of three Corinthian capitals placed upon one another; the other, which is the moſt beautiful, is varied in form by a tuft of acanthus leaves, which fall over like a canopy with a wonderful richneſs of appearance. The baſon of both is fluted, and by its form and ornaments correſponds with the magnificence of the whole.

Our own country poſſeſſes many ancient candelabra, two of admirable workmanſhip were preſented to the Radcliffe library at Oxford, by Sir Roger Newdigate; they were found in the ruins of the emperor Adrian's palace at Tivoli.

Of the ſecond claſs of candelabra there is a very curious collection in the muſeum of Portici, which were found in the excavations of Herculaneum and Pompeii. They are all of bronze, and were uſed for domeſtic purpoſes. In many of theſe we find the ſhaft repreſenting a knotted cane, or a ſpiny branch, with truncated ſhoots and leaf ſtalks. They may be cited as examples of the taſte of the ancients, in adapting ornaments to things of common uſe, to augment their utility, and, at the ſame time, preſerve the type of the objects which give riſe to any uſeful invention. The buds and ſhoots repreſented ornament the ſhafts of the candelabra, which would otherwiſe be too plain; they are convenient in affording a firm graſp to the hand, and at the ſame time they appear to give the hiſtory and agreeably recal the ſimple origin of theſe utenſils. The ſame art which in ſtone and marble preſerved the original forms of the wooden hut, has perpetuated in bronze the reed or ſtaff, which ſupporting a tablet, formed the primitive candelabrum.

Among the conſiderable number of the candelabra in the muſeum of Portici there are many varieties. Their greateſt height is five feet. The ſhaft of one of theſe is ſquare, and on the upper part, immediately below the tablet upon which the lamp was placed, is repreſented a double head, one face of Mercury, and the other of Perſeus. The greater number are in the form of a column placed upon a ſpreading baſe, compoſed of three paws, and above the ſhaft is placed a circular tablet, forming the lamp ſtand. The ornaments are various; in ſome the ſhaft is fluted longitudinally; in others, the flutings are formed ſpirally; and there is equal diverſity in the capitals.

Candelabra of this kind are not employed by any modern European nation: the diſuſe of theſe elegant utenſils is owing to the circumſtance of candles having ſuperſeded lamps.

In Italy the practice of placing round the altar large chandeliers ſeemed to be an imitation of ancient cuſtoms in this reſpect; the ſize and the ſhape even of ſome of theſe chandeliers preſerve a tolerably juſt idea of the ancient candelabra, but they differ eſſentially from theſe in the ſocket neceſſary to receive the candle, and ſupport it in a ſtraight and immoveable poſition, and ſtill more in the choice of forms and taſte of ornament. The fineſt, or, at leaſt, the moſt rich and boaſted modern works of this kind, are the chandeliers of St. Peter's, the deſign of which is attributed to Michael Angelo. Notwithſtanding the name of this great artiſt, the richneſs of the material, and the beauty of the workmanſhip, it muſt be confeſſed that their form is too much divided, the ornaments are capricious, and their proportion very inſufficient for the ſituation which they occupy.

CANDELARES, in *Botany*, the ſixty-ſecond order in Linnæus's fragments of a natural method publiſhed in the Philoſophia Botanica. It conſiſted of Rhizophora, Mimuſops, and Nyſſa: but was afterwards aboliſhed by him, and its three genera referred to the Holeraceæ.

CANDELARIA, in *Entomology*, a ſpecies of FULGORA peculiar to China, that poſſeſſes the power of emanating a clear and vivid light from the extremity of its ſnout in a ſimilar manner to that emitted from the abdominal rings of our common glow-worm (*lampyris noctiluca*). It is ſpecifically diſtinguiſhed from the Fulgoræ, by having the ſnout aſcending: wing-caſes green with pale yellow ſpots; wings yellow, and black at the tip. Linn. Fabr. Donov. Inſ. China. See alſo article FULGORA.

CANDELARO, in *Geography*, a river of Naples, which runs into the ſea, 3 miles S. of Manfredona.

CANDERN, a town of Germany, in the circle of Suabia, and margraviate of Baden-Dourlach; 11 miles N.E. of Bâle, and 52 S. of Straſburgh.

CANDEROS, in the *Materia Medica*, a name of an Eaſt Indian gum not much known among us, though ſometimes imported. It has much the appearance of common amber, only that it wants its yellow colour, being white and pellucid; we ſometimes ſee it turned into toys of various kinds, which are very light, and of a good poliſh. Garcias and ſome other authors tell us, that Borneo, and ſome other places where camphor is produced, have the art of adulterating the crude camphor, which they ſend over to us, with large quantities of this gum.

CANDES, in *Geography*, a town of France, in the department of the Indre and Loire, and chief place of a canton in the diſtrict of Chinon, at the conflux of the Vienne and Loire; 2 leagues N.W. of Chinon.

CANDETTA, a ſmall iſland in the Adriatic, near the coaſt of Greece. N. lat. 39°. E. long. 21°.

CANDIA, a large iſland in the Mediterranean, anciently called *Crete*, (which ſee), is about 60 leagues in length, and about 13 at its greateſt breadth, and partly ſituated under the 35th degree of N. lat. and compriſed between 23° 30′ and 26° 30′ E. long. For the early hiſtory of this iſland, ſee CRETE. Its firſt foreign maſters were the Romans; who reduced it to the ſtate of a Roman province in conſequence of the conqueſt of Q. Cæcilius Metellus, hence ſurnamed "Creticus," or the Cretan, in the year 66 B. C. In this ſtate of ſubjection to the Romans, under the emperors of the Eaſt, it continued till the Saracens, who had ſettled in Spain, induced by the fertility and pleaſantneſs of this iſland, equipped a fleet for ſubduing it. Accordingly they landed in a convenient place, and for their ſecurity built and fortified a city, called "Chandax," or "Candax," ſignifying in their language "entrenchment," A. D. 812. From hence they made frequent excurſions, and, in ſpite of the efforts of Michael II. ſurnamed Balbus, or the Stammerer, they ſoon after reduced the whole iſland, and called it "Chandax," which was afterwards changed into Candia. In 962, Nicephorus Phocas drove the Saracens from this iſland, and reunited it to the empire of the Eaſt, of which it formed a part till the capture of Conſtantinople by the cruſaders in 1204. In recompence of the ſervices which the Venetians had rendered to Baldwin in the ſiege of this city, Candia, together with ſome other iſlands in the Archipelago, was given to them. In 1207, this iſland was ſubdued by the Genoeſe; and in 1211, Boniface, marquis of Montferrat, ſold it to the Venetians. In 1646, the Turks made a deſcent upon the iſland; and, having captured Canea, and proſecuting the ſiege of Candia, which was one of the moſt bloody and deſperate that was ever recorded in hiſtory, they compelled the Venetians to ſurrender it, A. D. 1669; and the whole iſland, a few fortreſſes excepted, was ceded to the conquerors. In 1715, the Turks made themſelves maſters of the Venetian forts; and ſince this time the whole iſland has belonged to them.

Sonnini ſuggeſts that, as the iſland of Candia extends from eaſt to weſt, whilſt the other iſlands of the ſame ſea lie, with reſpect to their length, in a north or ſouth direction, ſomewhat inclining towards the eaſt or weſt, it was detached from Africa by an inundation of the low lands which formerly united them: and this junction of Candia with the coaſt of Barbary acquires, he ſays, an additional degree of probability, when we direct our attention to the ſhallowneſs of the channel which ſeparates them, whoſe bottom every where affords ſoundings. Candia reſembles the other iſlands of this part of the Mediterranean, in having a chain of high mountains, called, from the ſnow that covers them in the winter, the "White Mountains," that traverſes its whole length. The iſland is divided into three pachaliks, or governments, the chief places of which are Candia, Canea, and Retimo. In the firſt of theſe towns is a pacha with three tails, ſeraſkier, or general in chief of all the forces of the iſland. In the other two is a pacha with two tails, independent of that of Candia, as to the adminiſtration of the police, but ſubject to him in every thing that concerns the military department. All three, in their turn, and in their reſpective provinces, ſuperintend the collection of the impoſt, and the ſafety of the places that are entruſted to them. They alſo cauſe juſtice to be done by the Cadis, and order their ſentences to be executed. Each pachalik is divided into a certain number of diſtricts, and each diſtrict compriſes a certain number of villages, of which ſome belong to the imperial moſques, and others to the ſultana-mother; and the greater number are granted for life to agas, or lords, in conſideration of a ſum of money paid into the imperial treaſury, and an annual quit-rent, which is lodged in the coffers of the treaſurer of Candia, for the maintenance of the fortreſſes and the pay of the troops of the country. All land owners pay to the aga, to the moſque, or to the ſultan, a ſeventh of the produce of their lands; and they are obliged to carry their olives to the mills, which the agas alone have a right to cauſe to be conſtructed. Oil pays a ſeventh. The police of the village belongs to the aga, who appoints, for ſubordinate adminiſtration, a ſoubachi, or ſubaltern tyrant, more greedy and more untractable than his maſter. No Greek can marry without the permiſſion of the aga, which is to be purchaſed by a preſent; and the aga ſometimes appropriates the female who is propoſed for marriage to himſelf; and when he wiſhes to part with her, he marries her to ſome Greek inhabitant of the village, who dares not refuſe her. Married men are not allowed to quit the iſland, unleſs they are mariners, or merchants; but bachelors may go to work in the Morea, or elſewhere, upon paying a tax of 60 parats, or two piaſtres a head before their departure. If a murder happen in a village, or within its territory, and the delinquent be unknown, the aga muſt pay to the pacha a ſum of money, which is levied on all the inhabitants, reſerving a part for himſelf. Taxes are arbitrary, and in their amount depend on the population and circumſtances of the inhabitants. For the death of a muſſulman, the fine is exorbitant, and is almoſt always attended by the death of ſeveral Greeks. The Turkiſh villages, as well as thoſe of the Greeks, are ſubject to the police of the aga; but thoſe which belong to moſques or to the ſultana-mother, are leſs oppreſſed than the others. The Greeks can neither occupy employments proceeding from the government, nor can they be admitted into any corps of troops, unleſs they have embraced the religion of Mahomet. Thus the iſland, which long proſpered under the laws of Minos, is now governed; and thus the inhabitants of a country where liberty in a manner took its birth, are bent under the yoke of the moſt ignominious ſlavery. Among the people, who at this day inhabit the iſland of Candia, we may reckon Abadiots, Muſſulmen by religion, Arabs by origin, and ſome remains of the Saracens whoſe anceſtors formerly occupied it. The Abadiots are ſwarthy, meagre, and of middling ſtature, and in their diſpoſition miſtruſtful, malicious, and vindictive; they always go armed like the Turks, and kill each other on the ſmalleſt provocation. They occupy 20 little villages to the ſouth of mount Ida, and form a population of about 4000 perſons. They afford an aſylum to the Turks and Greeks who have committed any crimes, whom they themſelves kill if they become troubleſome. When they have an opportunity, they rob the friars in the Greek monaſteries that lie within the reach of their villages. The inhabitants of the high mountains to the ſouth of Canea and Retimo are conſidered as the real deſcendants of the ancient Cretans, and are known by the name of "Sphachiots." They are diſtinguiſhed from the other Greeks by their tall ſtature, handſome look, love of liberty, courage, ſkill, and above all, by the hatred which they have vowed againſt the uſurpers of their iſland. Theſe Sphachiots have found means to preſerve their laws and their cuſtoms under the Romans, the Saracens, the Venetians, and the Turks. Obliged by the Turks to tranſport, in ſummer, from the tops of their mountains, the ice neceſſary for the conſumption of the inhabitants of Canea and Retimo, they paid no tax nor import; they had no agas; they never ſaw among them the agents of the Turkiſh government; and they formed a republic, in ſome meaſure independent, till, in 1769, the happineſs which they enjoyed on their mountains was interrupted by the part they took with the Ruſſians, and the Turks retaliated upon them their revolt by hoſtile meaſures that proceeded almoſt to their utter extermination. The amount of the population of this iſland conſiſting of Greeks and Turks is eſtimated by Olivier at 240,000.

The climate of Candia has from remote antiquity been deemed ſingularly healthful, which has been attributed to the abundance of its ſalutary plants. Hippocrates ſent his patients thither to breath the air charged with wholeſome vapours. The Turks in the iſland of Candia, under the happy influence of its climate, have there acquired a taller ſtature, muſcles more prominent and more ſtrongly marked, broader cheſt and ſhoulders, all the proportions which conſtitute beauty and ſtrength, together with an impoſing ſtep and carriage; although with all theſe advantages, the ſternneſs of their countenance gives to their majeſtic exterior a formidable impreſſion. The Greeks, on the other hand, are of a ſtature leſs tall, a corpulence leſs prominent, a ſtep leſs ſolemn, a make leſs robuſt, but more graceful; and they ſeem to have degenerated under a climate which is natural to them, and in which they are abandoned to ſlavery, which alike degrades both the form of the body and that of the mind. The ſame diſparity in the exterior attributes of the Turk and the Greek, is alſo obſerved among the women of the two nations. The Turkiſh women are there handſomer than in the other parts of the eaſt; whereas the female Greeks have, generally ſpeaking, fewer charms than they poſſeſs in ſeveral other countries. The dance of the Greeks of Candia is referred to a very remote antiquity. Homer (Il. l. xviii. ſub fin. Pope's verſion.) has deſcribed it; and it is the image of the labyrinth of Crete, of which it imitates the windings and turnings. It is ſerious and grave, though not deſtitute of ſimplicity and nobleneſs. Their ſongs are ſlow and languid, and the habit which the Greeks have of ſinging through the noſe renders their ſongs ſtill more drawling and leſs ſprightly.

With the exception of the leproſy brought to this iſland from Aſia, there are no contagious nor prevailing diſorders in Candia.

One of the beſt cultivated and moſt productive of the provinces of this iſland is *Kiſſamos*. To the ſouth of this province is *Selino*, to the north of theſe two provinces is *Cidonia*, and to the ſouth *Sphachia*. Three leagues from the town of Canea commences the province of *Apocorona*, which extends to the eaſt as far as *Armiro*, and to the ſouth as far as the mountains of Sphachia. This province is mountainous, and furniſhes abundance of oil, but a ſmall quantity of barley and wheat, and very little wine. It is more peopled by Greeks than by Turks. The province of *Retimo* is well cultivated and very productive. To the ſouth of this are the two provinces of *Aion-Vaſſali* and *Amari*, furniſhing wheat, barley, oil, and ſome fruits. The former, ſituate N.W. of the other, ſupplies alſo excellent cheeſe. In theſe provinces the Greeks are more numerous than the Turks. The firſt province that occurs in the north part of the iſland, after quitting the territory of Retimo, is called *Nilo-Potamo*. The province of *Candia* affords very little cotton, but abundance of wheat and barley, and a conſiderable quantity of raiſins, which laſt are ſhipped for the ſupply of Syria and Egypt. In this territory there are ſcarcely any olive-trees. The Turks are here as numerous as the Greeks. To the ſouth of Candia lies the province of *Meſſara*, which is reckoned the granary of Crete; and to the eaſt of Candia lies the province of *Mirabel*, to the ſouth of which is the province of *Hiera Petra*, or *Gera-Petra*. The province of *Settia* occupies the whole eaſtern part of the iſland. For a more particular account of each of theſe provinces, ſee Kissamos, Selino, &c.

Notwithſtanding the various alimentary productions furniſhed by this iſland, the Greeks live through the whole year on barley-bread, ſalted olives, and wild plants. The more delicate articles of ſubſiſtence they ſell in order to diſcharge the taxes, or to pay the too frequent extortions of their agas. Mutton and pork are every where excellent and cheap. Lambs and kids are likewiſe to be obtained in the three principal towns during ſeveral months of the year. The argali and wild goat are plentiful on the mountains. Beef is ſcarce, and the ox is little uſed but in rural labour. Poultry may be procured with eaſe, and at a cheap rate. Turkeys are ſold at a very moderate price; and the iſland abounds with a great variety of birds fit for food, as the quail, turtle, ring-dove, loriot, roller, thruſh, and fig-peckers. The woodcock paſſes the winter in this iſland, and the blackbird remains all the year. In ſpring and ſummer, larks, ortolans, and many ſmall birds ſupply the place of birds of paſſage. The hare and partridge are very common. There are few countries in the Levant that afford a greater variety of uſeful and intereſting vegetables than the iſland of Crete. Agriculture is ſubject to many diſcouragements and reſtraints in the iſland of Candia; and induſtry is checked by the oppreſſion and rapine of the agas, pachas, and janizaries. Such is more eſpecially the caſe in the villages and territories belonging to the Greeks. The Turks are leſs oppreſſed; and the Sphachiot, more ſure of enjoying the fruits of his labour, exerts a greater degree of energy and activity. Public granaries are very common near the principal towns; they were probably conſtructed in the time of the Venetians, and they conſiſt of large ſquare pits in maſonry, coated with a cement capable of ſecuring from moiſture the grain contained in them. The opening is narrow, and carefully cloſed. As the iſland does not grow a ſufficient quantity of corn for the ſupply of its inhabitants, a large quantity is annually imported from Volo, Salonica, the Morea, Syria, and Egypt. Wine is made only in a few diſtricts; in others, the inhabitants prefer carrying their grapes to the town, or drying them for trade. The mulberry-tree vegetates very well in Candia, and ſilk-worms thrive wonderfully; and yet the ſilk uſed in their meaneſt manufacture is brought from Syria. Some cloths, in ſilk and cotton, and in ſilk and flax, are manufactured and conſumed in the country. Flax, though tolerably plentiful, is not cultivated in ſufficient quantity for the uſe of the inhabitants; a great deal is drawn from Egypt. Cotton is little cultivated; that which is conſumed being brought from Smyrna and the environs of Epheſus. Seſamum is cultivated for the purpoſe of mixing its ſeed with bread, in order to give it flavour. One of the productions of Candia, which has preſerved its ancient reputation, is wine, which, in ſome diſtricts, is ſtill delicious. It is well known, that Homer has praiſed the wine of Crete, and that Jupiter drank no other nectar during his ſtay in this iſland. The malmſey, which is made in the environs of mount Ida, is much eſteemed; but all the Candian wines muſt be drank with caution, as they are of a fiery quality, and apt to fly quickly to the head and to ſhake the nerves. In ſeveral places foreſts of pines, cedars, and firs cover the declivity of the mountains, and crown the ſummit of the hills; and afford, by their ſtraight and tall ſtems, as well as by the reſin which exudes from them, abundant reſources for nautical purpoſes. On the mountains in the vicinity of Canea, and at the foot of mount Ida, grows a ſpecies of rock-roſe (*Ciſtus ladaniferus*, Linn.), which yields ladanum, or labdanum, ſerving for perfumes and the preparation of certain drugs. The horſes of Candia, the race of which originally came from Barbary, have much degenerated in form and beauty. Nevertheleſs, none can be compared to them for ſtrength and ſuppleneſs of limbs, and for being ſure-footed. The dogs of the iſland were formerly reckoned, on account of their fleetneſs and agility, the beſt in Greece, next to thoſe of Lacedæmonia. But, under the Turks, their race is degenerated. The dogs of Candia are a new ſpecies of large greyhounds, or courſing dogs, which, with a little attention, might be handſome animals; but in this land of tyranny and ſlavery theſe animals are neglected. It is ſaid that in Candia no carnivorous and ferocious animal exiſts; and it is certain that if ſuch quadrupeds once inhabited this iſland, their races have entirely diſappeared. But the ancients have blended exaggeration with their accounts, when they aſſert that birds of prey would not ſubſiſt here. It was alſo aſſerted, without foundation, that the iſland of Candia was exempt from ſerpents, and other venomous animals. Pliny, however, has made an exception in favour of the phalangium, or tarantula. Belon has obſerved, that three ſpecies of ſerpents were known here; and Sonnini ſays, that there exiſts a ſpecies of ſpider as dangerous as the tarantula, which lives in ſubterraneous retreats, and is of the ſpecies of the maſon, or mining ſpider, circumſtantially deſcribed by Latreille in the "Mem. de la Societe d'Hiſt. Nat." Whether the gecko (*lacerta gecko*, Linn.) be found on this iſland is not abſolutely certain; but it is not improbable, as it is met with in other countries of the eaſt, in the vicinity of the iſland of Candia, and particularly in Barbary and Egypt. The hydrophobia is ſaid to have occaſionally, though ſeldom, made its appearance in Candia; and Dapper mentions that this iſland has been frequently afflicted by mad dogs. The remedy purchaſed by the king of Pruſſia, and publiſhed in 1777, is known there. The inſect that furniſhed this ſpecific, which the Candiots employed from time immemorial as a ſovereign antidote to madneſs, is the *meloe*, or oil-beetle, (*Meloe proſcarabæus*, Linn.) the larva of which bears the name of "May-worm." In Candia it is reduced to powder, which the patient ſwallows; and it is ſaid to be of ſo active a nature, as to occaſion convulſions, pains in the bowels, inflammations, agony, bleedings at the noſe, bloody urine, and even death, when taken in too large a doſe. Such dangerous means of cure have been wiſely relinquiſhed by modern practitioners. The multiplication of bees is a branch of rural induſtry, which is encouraged in this iſland. The ancients indeed feigned that Jupiter had been fed on the honey obtained from the bees of mount Ida.

The only articles of exportation from this iſland are, oil, ſoap, wax, honey, cheeſe, raiſins, almonds, walnuts, cheſnuts, St. John's bread, linſeed, and liquorice-root. The imports ſupplied by the French conſiſt of woollen cloths, laces, and ſtuffs of Lyons, imperial ſerges of Niſmes, ſmall ſhot, tin, iron, ſteel, coffee, ſugar, nutmegs, cloves, indigo, cochineal, paper, and various articles of hard-ware. Venice and Trieſte ſupply glaſs-ware, hard-ware, and, particularly, planks for making ſoap-caſes; and Caramania, or Greece, furniſhes almoſt all the wood neceſſary for the ſoap-houſes. The iſlanders themſelves carry on ſome trade: from Salonica they draw corn, cotton, tobacco, and iron; from Conſtantinople, Burſa ſtuffs, Angora châlits, ſhoes, handkerchiefs, and copper utenſils. At Smyrna they take hides, Turkey leather or Morocco, cotton, quilted coverlids, Engliſh ſhaloons, and ſome French goods. At Gaza they take aſhes for their ſoap-houſes: at Aleppo, ſilk ſtuffs; and they purchaſe on the coaſt of Syria corn and ſilk. Egypt ſupplies them with corn and rice, flax, linen-cloths, and aſhes. Derna and Bengazi, on the coaſt of Africa, ſend butter known under the name of Mantegue, which is a mixture of butter and mutton-ſuet, uſed by the orientals in their ragouts and paſtry. Tunis and Tripoli exchange their caps and their corn for ſoap and ſequins. The wool is coarſe and ſhort, and wholly conſumed in the country. The hone is a well known article of commerce from Candia and Stancho.

The north coaſt of this iſland has the greateſt number of harbours and roadſteads; in which are many excellent anchorages; but the ſouth coaſt affords few places where a ſhip can reſt in ſafety. The rivers of the iſland are principally torrents ſwelled in winter by the rains, and in ſpring by the melting of the ſnow; but they have a conſiderable number of ſprings, which the inhabitants uſe for the watering of their lands. During the three ſummer months, the exceſſive heat of the ſun is conſtantly tempered every day, from eight or nine in the morning till the evening, by the rapid current of air which prevails from North to South on the northern coaſt of the iſland. This refreſhing wind, called "embat," takes its courſe, and is modified through the Levant, according to the direction of the coaſts and the extent of ſea which lies before them. In the iſland of Candia winter is, properly ſpeaking, no more than a rainy ſeaſon, during which the ſky is more charged with clouds, and the heat leſs powerful, but never ſuch as to make it neceſſary to have recourſe to artificial warmth. However, in this ſeaſon the mountains are covered with ſnow, and in ſome places it remains till the month of June. Sonnini's Travels in Greece, p. 209, &c. Olivier's Travels in the Ottoman Empire, vol. ii. p. 180, &c.

Candia, the *Khandak* of the Arabs, derived from *chandax* or *candax*, is a maritime town of the iſland above deſcribed, and, though leſs populous and commercial than *Canea*, reckoned its capital. Some geographers have ſuppoſed that its ſcite is that of the ancient *Cytæum*; others ſuppoſe it to have been *Matium*, and others again refer it to *Heraclea*. Olivier places Cytæum 4 leagues to the weſt, and Matium 2 leagues to the eaſt, and Heraclea 4 or 5 leagues to the eaſt; and Candia he imagines to have been port *Panormus*, which lay, according to Ptolemy, between Cytæum and Heraclea. Candia is ſituated on a pleaſant plain, interſected by beautiful hills, which ſhare its fertility, and the ground on which it ſtands is ſupported towards the ſea by a ſtrong wall built on rocks, which affords an agreeable walk. The approaches of the place are defended by ſea with ſeveral pieces of cannon, and it is guarded on the land ſide by walls of a ſolid conſtruction, a good ditch, and ſome advanced works. The form of the town, conſiſting of ſtraight ſtreets and regular ſquares, and the ſubſtantial conſtruction of the buildings, indicate that it is not the work of the Turks, but that it owes its exiſtence to the Venetians: at the ſame time its preſent ſtate announces the dreadful ravages of war, and the ſlower havock of want, ſo that the houſes conſtructed by them have diſappeared. Here are ſtill to be ſeen ruins which are the remains of the memorable ſiege which it ſuſtained for twenty-four years, from 1646 to 1670, againſt the Ottoman forces. The decline of its commerce has changed its flouriſhing ſtate and conſiderably reduced the number of its inhabitants, many of whom are removed to Canea, together with the foreign merchants. Although it is ſtill the ſeat of the general government of the iſland, its population is diſproportioned to its extent. It now contains ſcarcely 10 or 12000 Turks, 2 or 3000 Greeks, and about 60 Jews. The Greeks, who inhabited it before it became ſubject to the Turks, followed the Venetians at the time of its capitulation, and made their eſcape into the country: nor have they returned to ſettle in a town, where their exiſtence is inceſſantly threatened by the Janizaries, and their fortune frequently invaded by the Pachas. The handſomeſt churches damaged by the above-mentioned ſiege have been repaired and converted into moſques; but the fortifications have been carefully preſerved. To the ſouth-weſt of Candia, the firſt chain of mount Ida riſes in the form of a pyramid, and ſeems at a diſtance as a land-mark to navigators, who wiſh to anchor in the harbour of that town. The harbour is defended from the north wind by rocks, on which has been built a ſtrong jetty parallel to the coaſt: it is very ſecure; and might contain from 30 to 40 merchant-veſſels, if it were kept in proper order. But the Turks have ſuffered it to be choaked up, ſo that there are no more than eight or nine feet of water in the inſide of the harbour, and about 15 at its entrance. It affords accommodation only to a few ſmall barks of the country; and merchant-veſſels can only enter it in ballaſt, or with a fourth of their lading. To this and other circumſtances it is owing that the trade of Candia is almoſt annihilated. Navigators who frequent the harbour of Candia have been furniſhed by a long ſeries of obſervations with means of aſcertaining the ſtate of the atmoſphere in the open ſea, from the ſole inſpection of the chain of mountains which encircles the town to the ſouth. When the clouds collect in heaps above the moſt prominent of theſe hills, which bears the name of "Calepo," the weather is bad in the offing, and the wind almoſt always to the northward; navigators then take care not to quit the harbour. If, on the contrary, the ridge of the mountain is clear and free from vapours, they are certain of finding, without, the wind moderate and favourable for ſailing out of the gulf, and getting clear of the coaſt.

The environs of Candia preſent a few fertile plains that are cultivated, and ſome riſing grounds ſuſceptible of cultivation. At a little diſtance to the ſouth is ſeen the inſulated pyramidal mountain already mentioned, at the foot of which is a paſſage to the ruins of Gortyna, and its labyrinth: to the Europeans this mountain is known by the name of Jupiter's mountain. To the ſouth-weſt, mount Ida, covered with ſnow almoſt all the year, throws out on one ſide ſome branches towards the town; and, on the other, runs to join the mountains of Sphachia, covered in like manner with ſnow during eight or nine months. In this town there are 25 ſoap-houſes, which employ the greater part of the oils of the province, and of thoſe ſituated in the eaſt part of the iſland. Candia forms one of the three pachalicks of the iſland. See Candia. N. lat. 35° 19′. E. long. 25° 18′.

Candia, a town of Italy, in the Milaneſe; 12 miles W. of Vercelli.

Candia, a townſhip of America in Rockingham county, New Hampſhire, N. of Cheſter; about 36 miles W. of Portſmouth; incorporated in 1767, and containing 1040 inhabitants.

CANDIDA, in *Conchology*, a ſpecies of Arca, the ſhell of which is pellucid, rhomboid, produced in front, truncated behind, and decuſſated with ſtriæ; beaks remote; poſterior margin gaping, the opening ovate and ciliated. Chemnitz, &c. A native of the American and African ſhores. This kind is white, ſomewhat granulated, and covered with a blackiſh ſubfuſcous epidermis.

Candida, in *Zoology*, a ſpecies of Actinia, deſcribed by Mülleri as a native of the northern ſeas of Europe. This is ſmooth, with a rugoſe aperture, the tentacula reſembling briſtles, and diſpoſed at the margin.

CANDIDATE, a perſon who ſets up for ſome poſt or place, either of honour or profit.

The word is formed of *candidus*, white; on account of a white ſhining garment, *toga candida*, in which thoſe who aſpired to preferments in ancient Rome were habited, at the time of their appearing for the ſame, eſpecially at the public aſſemblies, in order to diſtinguiſh them from the crowd. The white gown worn by candidates was looſe and ungirded, nor was there any cloſe garment under it, which ſome interpret as done with deſign to avoid any ſuſpicion people might have of bribery; though Plutarch rather thinks it done to gain the affections of the people, by ſuing in ſuch an humble garb; or elſe that ſuch as had received wounds in the ſervice of their country, might more eaſily exhibit thoſe tokens of their courage and fidelity. The Roman candidates uſually declared their pretenſions a year before the time of election, which was ſpent in making intereſt and gaining friends. Various arts of popularity were practiſed for this purpoſe, and frequent circuits made round the city, and viſits and compliments to all ſorts of perſons, the proceſs of which formed what was called AMBITUS.

Candidate *of baptiſm*, in the *Ancient Church*, was called CATECHUMEN.

Candidates, in the College *of Phyſicians*, London, is the order of members, out of whom the fellows are choſen.

The candidates muſt be natives of England, doctors of phyſic, admitted to the degrees in our own univerſities, and ought to have practiſed phyſic four years before they are admitted into the order. The number of candidates is never to exceed twelve. See College.

Candidate, in *Academical Orders* or *Degrees*, denotes a perſon to whom, after full examination, and the performance of inaugural exerciſes, licence is granted to take up the higheſt or doctoral dignity when he pleaſes. See Degree, Doctor, Licentiate, &c.

Candidati *principis*, were thoſe who were recommended to any offices by the emperors. The *candidatus principis* was alſo an office in the court of the emperor of Conſtantinople, anſwering to a ſecretary of ſtate among us.

The *candidatus principis* was denominated *Quæſtor principis*, or *Auguſti*.

Candidati *milites*. Among the Romans, theſe were ſoldiers diſtinguiſhed by their figure, ſtature, and valour in combat. They were placed near the emperor, who was an eye-witneſs of their exploits. They ſerved him as his body-guards to protect and defend him. It is ſaid that Gordian the younger firſt inſtituted them as well as the Protectores and Scholares; which articles ſee.

CANDIDUM, in *Conchology*, a ſpecies of Buccinum, deſcribed by Martini. This ſhell is oblong, turbinated, ſolid, ſmooth, and white. Country uncertain.

Candidum, *promontorium*, in *Ancient Geography*, *Bas-el-Abeaoh*, a promontory of Africa, N. W. of that of Apollo; mentioned by Livy, Pliny, and Mela.

CANDIDUS, in *Entomology*, a ſpecies of Cerambyx, (*Saperda*, Fabr.) Colour white; thorax and body fuſcous, with two white ſtripes. Fabricius. The country of this inſect is unknown.

CANDIL, in *Commerce*, an Eaſt Indian weight equal to 540 pounds avoirdupois.

CANDIPATNA, in *Ancient Geography*, a town of India, on this ſide of the Ganges, in the country of the Arvarnians, according to Ptolemy.

CANDLE, a cotton or linen wick, looſely twiſted, and covered with tallow, wax, or ſpermaceti, in a cylindrical figure; which, being lighted at the end, ſerves to illuminate a place in the abſence of the ſun.

The word *candle* comes from *candela*, and that from *candor*, of *candeo*, *I burn*; whence alſo the middle age Greek [illegible].

A tallow candle, to be good, muſt be half ſheep's and half bullock's tallow; the fat of hogs makes them gutter, gives an ill ſmell, and a thick black ſmoke.

Tallow candles are of two kinds; the one dipped, the other moulded: the firſt, which are thoſe in ordinary uſe, are of an old ſtanding; the latter are ſaid to be the invention of the ſieur le Brez, at Paris. The manufacture of the two kinds is very different, excepting in what relates to melting of the tallow, and making the wick, which is the ſame in both.

Candles, *method of making*. The different kinds of tallow being weighed and mixed in their due proportion, are cut or hacked into pieces, to facilitate their melting, and thrown into a pot or boiler, having a cavity of ſome depth running round the top, to prevent its boiling over. Being thus perfectly melted and ſkimmed, a certain quantity of water is thrown in, proportioned to the quantity of tallow; this ſerves to precipitate the impurities of the tallow, which had eſcaped the ſkimmer, to the bottom of the veſſel. The tallow, however, intended for the firſt three dips, muſt have no water; becauſe, the dry wick imbibing the water readily, makes the candles ſpit and crackle in the burning. The melted tallow is now emptied through a ſieve into a tub, having a tap for letting it out, as occaſion requires. The tallow, thus prepared, may be uſed after having ſtood three hours; and will continue fit for uſe twenty-four hours in ſummer, and fifteen in winter. The wicks are made of ſpun cotton, which the chandlers buy in ſkeins; and they wind off three or four together, according to the intended thickneſs of the wick, into bottoms, or clues, from a certain number of which threads are drawn off, and then cut with an inſtrument contrived for that purpoſe, into pieces of the ſize and length of the candle required. The machine for cutting the cotton conſiſts of a ſmooth board adapted to reſt on the knees; (ſee *Plate*, *Candle-Making*, *fig.* 1.) on the upper ſurface of which are the blade of a razor, or a knife, A, and a pin or round piece of cane, B, placed at a certain diſtance from one another, according to the length of the cotton that is wanted: the cotton is then carried round the cane, B, and being brought to the razor, or knife, A, is inſtantly ſeparated from the ſeveral bottoms or balls. The next operation is that of "pulling the cotton," which is that of laying ſmooth the threads, removing all knots, &c. and thus rendering it fit for uſe. It is then put on the ſticks, or broaches, or elſe placed in the moulds, as the candles are intended to be either dipped or moulded. The broaches are rods about half an inch in diameter, and ſomewhat more than three feet long.

Candles, *making of dipped*. The liquid tallow is drawn off from the tub above mentioned, into a veſſel called the mould, ſink, or abyſs, of an angular form, perfectly like a priſm, except that it is not equilateral, the ſide on which it opens being only ten inches high; and the others, which make its depth, fifteen. On the angle, formed by the two great ſides, it is ſupported by two feet, and is placed on a kind of bench, in form of a trough, to catch the droppings, as the candles are taken out at each dip. At a convenient diſtance from this is ſeated the workman, who takes three ſticks, or broaches at a time, ſtrung with the proper number of wicks, viz. ſixteen, if the candles are to be of eight in the pound; twelve, if of ſix in the pound, &c. and holding them equidiſtant, by means of the ſecond and third finger of each hand, which he puts between them, he immerges the wicks two or three times for their firſt lay, and, holding them ſome time over the opening of the veſſel to let them drain, hangs them on a rack, or frame, where they continue to drain and grow hard. When cooled, they are dipped a ſecond time, then a third as before; only for the third lay they are immerged but twice, in all the reſt thrice. The operation is repeated more or leſs times, according to the intended thickneſs of the candles. With the laſt dip they neck them; i. e. plunge them below that part of the wick where the other lays ended. Such as we have above deſcribed uſed to be the laborious method of making common candles; till within 15 or 20 years paſt, when an invention was introduced which ſerved very much to diminiſh the labour and to facilitate the operation. This method of making dipped candles, as now practiſed by the manufacturers in London, is as follows: the wicks prepared as above are hung at equal diſtances upon the broaches; and when five of theſe are filled, they are put into holes in two pieces of wood, C, D, (*fig.* 2.); thus forming a frame full of wicks. The veſſel, A, (*fig.* 1.) is then filled with melted tallow. This veſſel is made of lead, and has a hole, B, under it for receiving a chaffing-diſh to keep the tallow warm; on each ſide of the veſſel are two leaves, C, D, for catching the droppings of the candles as they are dipped; over the veſſel is ſuſpended from the ceiling a framed lever, K, K, with two arched heads, L, L, at each end, in order to give a vertical motion to the ſcale, I, and frame, EFGH, the two croſs pieces, E, F, of which are for the leaves, C, D, of *fig.* 2. to reſt upon. The dipper then lays hold of the upper bar at G and H, and gently puſhes down the wicks into the melted tallow, and keeps them down till he finds that, by the tallow adhering to them, they are heavier than the weight in the ſcale I, previouſly adjuſted to the proper weight. The frame of candles is then removed and hung up to cool, which takes ſome days, according to the ſtate of the weather. When they are quite ſtiff, they are dipped again with a heavier weight in the ſcale I, and this operation is continued, till they are of the proper ſize. The workman, by means of this ſimple contrivance, has only to guide the broaches and candles, and not to ſupport the weight of them as in the old method.

It muſt be obſerved, that during the operation the tallow is ſtirred from time to time, and the ſtock ſupplied with freſh tallow. When the candles are finiſhed, their peaked ends, or bottoms, are taken off; not with any cutting inſtrument, but by paſſing them over a kind of flat brazen plate, heated to a proper pitch by fire underneath, which melts down as much as is requiſite.

Candles, *method of making mould.* Theſe candles are made in moulds of different materials; that generally uſed is pewter. Each candle has its mould, conſiſting of three pieces, the neck, ſhaft, and foot: the ſhaft is a hollow pewter cylinder, B, (*fig.* 6.) having the end *a* ſomewhat ſmaller than the other, that the candle may ſlide out eaſily, of the diameter and length of the candle propoſed; at the extremity of this is the neck, A, which is a little metallic cavity, in form of a dome, having a moulding withinſide, and pierced in the middle with a hole big enough for the wick to paſs through. At the other extremity is the foot, in form of a little tunnel, through which the liquid tallow runs into the mould. The neck is ſoldered to the ſhaft, but the foot is moveable, being applied when the wick is to be put in, and taken off again when the candle is cold. A little beneath the place where the foot is applied to the ſhaft, is a kind of ſtring of metal, which ſerves to ſupport that part of the mould, and to prevent the ſhaft from entering too deep in the table to be mentioned hereafter. Laſtly, in the hook of the foot, is a leaf of the ſame metal, ſoldered within ſide, which, advancing into the centre, ſerves to keep up the wick; which is here hooked on, preciſely in the middle of the mould. The wick is introduced into the ſhaft of the mould by a piece of wire, which being thruſt through the aperture of the hook, till it come out at the neck, the wick is tied to it; ſo that in drawing it back, the wick comes along with it, leaving only enough a-top for the neck; the other end is faſtened to the hook, which thus keeps it perpendicular, E E (*fig.* 5.) Ten or fifteen of theſe moulds, in this condition, are fixed in a frame pierced full of holes, the diameter of each being about an inch, by a ſcrew at the top of each mould, which attaches them to the upper board B of the frame. This board has three upright ſides and one ſloping, which forms a ſmall ciſtern for the tallow. When every mould in the frame has been provided with a wick, two wires, *c c*, (*fig.* 5.) are paſſed through the two ends of the ciſtern at the top of the frame, and the loops of the ſeveral wicks. The ends of the wicks which hang out of the mould are pulled tight, their tops are put over the centers of the moulds, and the friction of the mould keeps them in this poſition. Theſe moulds are filled with tallow out of a ciſtern, A (*fig.* 4.) the outſide of which is wood, and lined with lead; within which is another ciſtern of lead for containing the melted tallow, prepared as above, with about two inches ſpace between them all round to be filled with hot water for keeping the tallow warm. In the bottom of the veſſel are three ſmall ſhuttles, B, C, D, communicating with the inner veſſel, and ſerving to fill the moulds, E E, before deſcribed. After the frame is filled and the tallow has acquired its due conſiſtence, the two wires, *c c*, are withdrawn, and the looſe tallow in the ciſtern at the top of the frame ſcraped out; they are ſet out in the open air to cool, and when thoroughly cold, the candles are pulled out of the mould by a bodkin put through the loops of the wicks where the wires, *c c*, paſſed before.

Thoſe who aim at perfection in their work, bleach or whiten their candles, by faſtening them on rods or broaches, and hanging them out to the dew, and earlieſt rays of the ſun, for eight or ten days: care being taken to ſcreen them in the day-time from the too intenſe heat of the ſun, and in the night from rain, by waxed cloths. Tallow-chandlers make other candles, which are intended to burn during the night without the neceſſity of being ſnuffed. The wick of theſe has been uſually made of ſplit ruſhes; but of late, very ſmall cotton wicks have been ſubſtituted for the ruſh; theſe are much more eaſily lighted, are leſs liable to go out, and, on account of the ſmallneſs of the cotton wick, they do not require the aid of ſnuffers. The price of candles uſed formerly to be regulated by the maſters and wardens of the tallow-chandlers' company, who were accuſtomed to meet at their hall every month for the purpoſe; but now the price of every article belonging to the trade is fixed at the weekly markets.

Candles, *wax*, are made of a cotton or flaxen wick, ſlightly twiſted, and covered with white or yellow wax. Of theſe there are ſeveral kinds; ſome called tapers, uſed to illuminate churches, and in proceſſions, funeral ceremonies, &c. and others uſed on ordinary occaſions.

As to the firſt kind, their figure is conical, ſtill diminiſhing from the bottom, which has a hole to receive the point in the candleſtick, to the top, which ends in a point: the latter kind are cylindrical. The firſt are either made with a ladle, or with the hand.

Candles, *wax, manner of making with the ladle.* The wicks being twiſted, and cut off at the proper length, a dozen of them are tied by the neck, at equal diſtances, round an iron circle, ſuſpended directly over a large baſon of copper tinned, and full of melted wax: a large ladle full of this wax is poured gently, by inclination, on the tops of the wicks, one after another; ſo that running down, the whole wick is thus covered; the ſurplus returning into the baſon, where it is kept warm by a pan of coals underneath it. They thus continue to pour on the wax, till the candle arrive at its deſtined ſize: ſtill obſerving, that the three firſt ladles be poured on at the top of the wick, the fourth at the height of $\frac{3}{4}$, the fifth at $\frac{1}{2}$, and the ſixth at $\frac{1}{4}$: by which means the candle arrives at its pyramidal form. The candles are then taken down hot, and laid aſide of each other, in a feather-bed folded in two, to preſerve their warmth, and keep the wax ſoft: they are then taken and rolled, one by one, on an even table, uſually of walnut-tree, with a long ſquare inſtrument of box, ſmooth at the bottom. The candle being thus rolled and ſmoothed, its big end is cut off, and a conical hole is made in it.

Candles, *wax, manner of making by the hand.* The wick being diſpoſed, as in the former, they begin to ſoften the wax, by working it ſeveral times in hot water, contained in a braſs caldron, tinned, very narrow and deep. A piece of the wax is then taken out, and diſpoſed, by little and little, around the wick, which is hung on a hook in the wall, by the extremity oppoſite to the neck; ſo that they begin with the big end, diminiſhing ſtill, as they deſcend towards the neck. In other reſpects, the method is the ſame here as in the former caſe; only that they are not laid in the bed, but are rolled on the table, juſt as they are formed. It muſt be obſerved, however, that in the former caſe, water is always uſed to moiſten the ſeveral inſtruments, to prevent the wax from ſticking; and in the latter, lard, or oil of olives, for the hands, table, &c.

Candles, *wax cylindrical,* are made either with the ladle, or drawn. The firſt kind are made of ſeveral threads of cotton, looſely ſpun, and twiſted together, covered with the ladle, and rolled, as the conical ones, but not pierced.

Candles, *wax, drawn,* are ſo called, becauſe actually drawn, in the manner of wire, by means of two large rollers, or cylinders of wood, turned by a handle, which turning backwards and forwards ſeveral times, paſs the wick through melted wax, contained in a braſs baſon; and at the ſame time through the holes of an inſtrument, like that uſed for drawing wire, faſtened at one ſide of the baſon: ſo that, by little and little, the candle acquires any bulk, at pleaſure, according to the different holes of the inſtrument through which it paſſes: by this method, may four or five hundred ells at length be drawn, running. The invention of this was brought from Venice by Pierre Bleſimare of Paris, about the middle of the 17th century.

The aſcent of the tallow up the wick in a burning candle, may be reſolved into the ſame principle of filtration, or attraction, as that of water up a heap of aſhes, or even up a capillary tube. The wick of a candle is but ſlightly twiſted, that all its hairs may be eaſily come at; which being very ſmall, ſoon take the flame: and the flame by its heat rarefying the air, and diſſolving the tallow underneath, makes the globules thereof aſcend into the rarefied ſpaces of the wick, and theſe, with the air about it, prove food for the flame.

A patent was granted in 1799, to Mr. William Bolts of London, for new modes of improving the form, quality, and uſe of candles. The moſt material alteration in Mr. Bolts's invention from the common method of making candles, conſiſts in ſaving the greater part of the wick by rendering it moveable; and for this purpoſe it is kept conſtantly ſoaking in the tallow as it melts, ſo that the cotton is conſumed very ſlowly as in lamps fed with oil. The patentee employs two methods for accompliſhing this object; one is that of making candles entirely ſolid, without any wick paſſing through them; and applying the wick, which is very ſhort, upon the top of the ſolid candle, where it burns like that of a lamp; the heat which it affords when firſt lighted being ſufficient to furniſh the firſt ſupply of melted tallow, and to continue it as long as any part of the candle remains unconſumed. In order to keep the wick conſtantly applied, it is faſtened to a ſmall projecting ſpring, into which it is firmly fixed; and the ſurface of the candle is always kept in contact with the wick, either by cauſing the wick ſtand to paſs round the candle like a collar, which moving freely on the candle, will ſink in proportion as this is conſumed, or by making the wick ſtand immoveable, and putting a ſpiral ſpring at the bottom of the candleſtick, which conſtantly protrudes the candle upwards againſt the wick in proportion as the tallow is conſumed. His ſecond method of conſtructing the candles is that of forming them in the uſual ſhape, but with a perforation through their whole length; and the wick in this caſe is a ſmall tuft of cotton, which is put into the opening at the top of the hollow candle, and to its lower part is attached a thread which paſſes down through the perforation to the bottom of the candle, where it penetrates the candleſtick, and is wound round a key or pivot, and by turning this pivot, the wick that is attached to the upper part of the thread will be pulled down in proportion as the candle conſumes. This method prevents the guttering of candles, as all the tallow that is melted is readily abſorbed by the wick. By a ſmall variation in the form of the candle, it may be made to ſerve the purpoſe of an Argand's lamp; for which end it is compoſed of a hollow cylinder of tallow, including another cylinder alſo perforated; and the wick, which is of a circular form, is here placed between the inner and outer cylinders. In all theſe caſes, the wick is compoſed of thread, placed longitudinally, and not twiſted, as is the caſe with the common wicks, which undoubtedly aſſiſts the capillary attraction of the melted tallow. Theſe wicks have alſo the advantage of not requiring to be ſnuffed, for removing the carbonaceous matter which eſcapes unconſumed from the tallow. Another advantage attending theſe detached wicks, is the eaſe with which their bulk may be proportioned to that of the candle, and to the fuſibility of the material of which it is compoſed. The patentee alſo propoſes another improvement, which is that of ſubjecting the melted tallow or other material to a conſiderable preſſure, during the act of cooling; which is done by means of a condenſing machine, preſſing the ſurface of the liquid ſubſtance, and then giving it a greater degree of firmneſs and ſolidity when cold. The patentee has likewiſe deſcribed, and illuſtrated by a drawing, the contrivance which he has adopted for caſting the hollow cylindrical candles. For a detail of other circumſtances that occur in his patent, we refer to his ſpecification in the Repertory, vol. xii. p. 368.

Candles, *laws relating to.* Every maker of candles for ſale, other than wax candles, ſhall take out an annual licence at 1l. 24 Geo. III. c. 41. 43 Geo. III. c. 69. And every perſon making wax or ſpermaceti candles ſhall take out a licence at 6l., and for dealing in, or ſelling ſuch candles ſhall pay 10s. 6d., and renew the ſame annually, under a penalty of 20l. 24 Geo. III. c. 36. 43 Geo. III. c. 69. But no perſon who hath paid ſuch licence duty for making, ſhall be obliged to take out a licence for ſelling alſo, during the ſame year. 24 Geo. III. c. 41. By 24 Geo. III. c. 74., no perſon, reſiding within the limits of the head-office, ſhall be permitted to make candles, unleſs he occupy a tenement of 10l. a year, aſſeſſed in his own name, and for which he pays the pariſh rates; and elſewhere, unleſs he be aſſeſſed and pay to church and poor. By 43 Geo. III. c. 69., in lieu of any ſubſiſting duties of exciſe, the following duties are impoſed; viz. for every pound avoirdupois of candles, except thoſe of wax and ſpermaceti, made in Great Britain, 1d.; and for every pound of wax or ſpermaceti candles ſo made, $3\frac{1}{2}$d. All places for making or keeping of candles, and of materials for the ſame, and furnaces, moulds, &c. for melting ſuch materials, are forbidden to be uſed without notice previouſly given in writing at the next office of exciſe, under a penalty of 50l., and forfeiture of all candles and materials, furnaces, &c. which have not been entered. 8 Ann. c. 7. And by 11 Geo. c. 30., makers of candles who make uſe of ſuch places or utenſils without entry incur a forfeiture of 100l. Officers ſhall be permitted, at all times by day, and alſo in the night with a conſtable, to enter the houſe, melting-houſe, &c. of a maker of candles, and to take an account of the quantity, when all cheſts, &c. ſhall be opened; and the penalty of obſtructing or moleſting ſuch officer is 100l.; or if candles, &c. be found in unentered places, the offender ſhall be convicted in the penalty of 100l. 11 Geo. c. 30.; ſee alſo 24 Geo. III. c. 11. and 27 Geo. III. c. 31. Any maker of candles ſhall give notice in writing to the proper officer of his intention to begin a courſe of dipping and preparing for the ſame, with a declaration of the time when he intends to commence his operation, and a ſpecification of the number of ſticks, moulds, &c. which he propoſes to uſe, under a penalty of 50l. 10 Ann. c. 26. 11 Geo. c. 30. 24 Geo. III. c. 11. Such notice ſhall be given, within the limits of the head-office, 6 hours, within any city or market town, 12 hours, and elſewhere 24 hours, before he ſhall begin, on pain of forfeiting 50l. 25 Geo. III. c. 74. If he does not begin and proceed at the time mentioned, or within 3 hours next after, ſuch notice ſhall be void. Having begun, he ſhall continue working without interruption, till the whole courſe is finiſhed, on pain of forfeiting 50l. 26 Geo. III. c. 77. Every candle-maker ſhall provide ſufficient locks and faſtenings to every furnace, copper, mould, &c. to be ſecured by the officer, when they are not uſed; and he ſhall give notice in writing to the ſaid officer, 6 hours before the time when he wiſhes to uſe them, within the limits of the chief office, 12 hours in any market town, and 24 hours elſewhere; any offence againſt the proviſions of this act incurs a penalty of 100l. 27 Geo. III. c. 31. The officer ſhall charge for materials that are miſſing, after he has taken account of the ſame; and obſtruction incurs a forfeiture of 20l. Candles that are ſpoiled in making ſhall be defaced by the officer, and he ſhall make allowance for the duty. No maker of candles ſhall, on pain of 20l., remove candles before they are ſurveyed; and thoſe that have not been ſurveyed are to be kept ſeparate from the others, on pain of 5l. 8 Ann. c. 9. On ſuſpicion, that candles are privately made, or concealed to evade the duty, the ground of which has been ſtated on oath before two commiſſioners or one juſtice reſiding near the place, the officer may be empowered by ſpecial warrant, granted by ſuch juſtices or commiſſioners, to enter the place ſuſpected, and to ſeize as forfeited all candles that are found, and all materials for making them; and the perſon ſo offending, or obſtructing the officer, ſhall forfeit 100l. 5 Geo. III. c. 43. 23 Geo. II. c. 24. If any chandler ſhall mingle candles not weighed by the officer with thoſe that have been weighed, or remove any before weighing, or conceal any candles or materials, he ſhall forfeit 100l. 11 Geo. c. 30. Any perſon who is found aſſiſting in privately making candles ſhall forfeit 20l.; and every perſon making candles ſhall once in every week enter the ſame in writing at the next exciſe-office, with their weight, number, ſize, and quantity; on pain for every neglect of entry to forfeit 20l.; and in one week, after ſuch entry, he ſhall clear off the duties, on pain of double duty, nor ſhall he carry out candles till the duty hath been paid, on pain of double value. 25 Geo. III. c. 74. Perſons buying, receiving, or having in their poſſeſſion candles, not charged with the duty, ſhall forfeit the ſame, and treble value. 26 Geo. III c. 77. Nor ſhall any perſon expoſe to ſale any candles, unleſs in his public ſhop or warehouſe, public fair or market, on pain of 5l. 8 Ann. c. 9. No candles ſhall be imported, otherwiſe than in ſome package containing at leaſt 224lb. of neat candles, on pain of being ſeized and forfeited, and the maſter of the veſſel ſhall forfeit 50l. 23 Geo. II. c. 21. 42 Geo. III. c. 93. And no candles imported otherwiſe than according to 23 Geo. II. c. 21., ſhall be entered for exportation. 42 Geo. III. c. 93. All wax candles ſeized on importation or otherwiſe, and condemned for non-payment of the duties, ſhall be rendered unfit for uſe. 24 Geo. III. c. 36. Candles for which the duty hath been paid may be exported, with a draw-back of the duty. 8 Ann. c. 9. 43 Geo. III. c. 69. If any maker of candles ſhall obſtruct any officer in the execution of the powers given him by any act for ſecuring the duties on candles, he ſhall for every ſuch offence forfeit 100l. 24 Geo. III. c. 11. Every maker ſhall keep juſt ſcales and weights, and permit and aſſiſt the officer in the uſe of them, on pain of 10l. 8 Ann. c. 9.; and if he uſe ſcales and weights that are inſufficient, he ſhall forfeit 100l. 10 Geo. III. c. 44.; and by 28 Geo. III. c. 37., the ſame ſhall be forfeited, and may be ſeized by any officer of exciſe. Obſtruction of the officer in weighing or the hindrance of his taking a juſt account of ſtock, ſubjects to a forfeiture of 100l. 26 Geo. III. c. 77.

CANDLES, *Obſervations on the manufacture, comparative value, and uſe of different.* The Roman candles were at firſt little ſtrings dipped in pitch, or ſurrounded with wax; though afterwards they made them of the papyrus, covered likewiſe with wax; and ſometimes alſo of ruſhes, by ſtripping off the outer rind, and only retaining the pith. For religious offices, wax candles were uſed; for vulgar uſes, thoſe of tallow. Serv. ad. Æn. l. i. v. 731. Plin. Nat. Hiſt. l. xvii. c. 37. Lord Bacon propoſes candles of divers compoſitions and ingredients, and alſo of different ſorts of wicks; with experiments on the degrees of duration, and light of each. Good houſewives are ſaid to bury their candles in flour, or bran, which, it is ſaid, increaſes their durability, almoſt one half. Some ſpeak of perpetual candles made of Salamander wood. Bac. Nat. Hiſt. Cent. 4. c. 369. and Cent. 8. c. 744.

The two ſubſtances moſt commonly uſed in the manufacture of candles are wax and tallow. Wax owes its whiteneſs, and the greater conſiſtency it acquires, to an abſorption of the vital part of the atmoſphere; and in this circumſtance it ſeems principally to differ from tallow, or concrete oil. But as wax is already combined with a portion of vital air or oxygene, it does not burn with ſo luminous a flame as tallow or oil. But it poſſeſſes a very great advantage in the fabrication of candles, ariſing from its freezing point being placed at a conſiderably higher temperature than that of the other ſubſtance. Tallow melts at the 92d. degree of Fahrenheit's thermometer; ſpermaceti at the 133d. degree; and bleached wax at 155°. Hence it will not be difficult to explain the chief advantage of wax candles compared with thoſe of tallow. Oils, it ſhould be conſidered, do not take fire, unleſs they be previouſly volatilized by heat: and this is effected by means of the wick of a candle, or lamp. The oil riſes between the fibres of the wick by the capillary attraction. Heat, being applied to the extremity of the wick, volatilizes and ſets fire to a portion of the oil. While this is diſſipated by combuſtion, another portion paſſes along the fibres, or ſupplies its place by becoming heated and burned likewiſe. In this way a conſtant combuſtion is maintained. A candle, however, differs from a lamp in one very eſſential circumſtance; viz. that the oil, or tallow, is liquefied only as it comes to be in the vicinity of the conflagration; and this fluid is retained in the hollow of the part, which is ſtill concrete, and forms a kind of cup. The wick, therefore, ſhould not, on this account, be too thin; becauſe if this were the caſe, it would not carry off the fluid as faſt as it becomes fuſed; and the conſequence would be, that it would run down the ſides of the candle: and as this inconvenience ariſes from the fuſibility of the oil, it is plain that a more fuſible candle will require a larger wick; or that the wick of a wax candle may be made thinner than that of one of tallow. The flame of a tallow candle will of courſe be yellow, ſmoky, and obſcure, except for a ſhort time after ſnuffing. When a candle with a thick wick is firſt lighted, and the wick ſnuffed ſhort, the flame is perfect and luminous, unleſs its diameter be very great; in which laſt caſe, there is an opake part in the middle, where the combuſtion is impeded for want of air. As the wick becomes longer, the interval between its upper extremity, and the apex of the flame is diminiſhed; and conſequently the oil, which iſſues from that extremity, having a leſs ſpace of ignition to paſs through, is leſs completely burned, and paſſes off partly in ſmoke. This evil increaſes, until at length the upper extremity of the wick projects beyond the flame and forms a ſupport for an accumulation of ſoot which is afforded by the imperfect combuſtion, and which retains its figure, until, by the deſcent of the flame, the external air can have acceſs to the upper extremity. But in this caſe, the requiſite combuſtion which might ſnuff it, is not effected; for the portion of oil emitted by the long wick is not only too large to be perfectly burned, but alſo carries off much of the heat of the flame, while it aſſumes the elaſtic ſtate. By this diminiſhed combuſtion, and increaſed efflux of half-decompoſed oil, a portion of coal or ſoot is depoſited on the upper part of the wick, which gradually accumulates, and at length aſſumes the appearance of a fungus. The candle does not then give more than one-tenth of the light which the due combuſtion of its materials would produce; and, on this account, tallow candles require continual ſnuffing. But if we direct our attention to a wax candle, we find that as its wick lengthens, the light indeed becomes leſs. The wick, however, being thin and flexible, does not long occupy its place in the centre of the flame; neither does it, even in that ſituation, enlarge the diameter of the flame, ſo as to prevent the acceſs of air to its internal part. When its length is too great for the vertical poſition, it bends on one ſide; and its extremity, coming in contact with air, is burned to aſhes; excepting ſuch a portion as is defended by the continual afflux of melted wax, which is volatilized, and completely burned, by the ſurrounding flame. Hence it appears, that the difficult fuſibility of wax renders it practicable to burn a large quantity of fluid by means of a ſmall wick; and that this ſmall wick, by turning on one ſide in conſequence of its flexibility, performs the operation of ſnuffing upon itſelf, in a much more accurate manner than it can ever be performed mechanically. From the above ſtatement it appears, that the important object to ſociety of rendering tallow candles equal to thoſe of wax, does not at all depend on the combuſtibility of the reſpective materials, but upon a mechanical advantage in the cup, which is afforded by the inferior degree of fuſibility in the wax: and that, in order to obtain this valuable object, one of the following effects muſt be produced: either the tallow muſt be burned in a lamp, to avoid the gradual progreſſion of the flame along the wick; or ſome means muſt be deviſed to enable the candle to ſnuff itſelf, as the wax-candle does; or the tallow itſelf muſt be rendered leſs fuſible by ſome chemical proceſs. With a view to the firſt of theſe objects, a cylindrical piece of tallow was inſerted into a metallic tube, the upper aperture of which was partly cloſed by a ring, and the central part occupied by a metallic piece nearly reſembling that part of the common lamp which carries the wick. This piece was provided with a ſhort wick. The cylinder of tallow was ſupported beneath in ſuch a manner that the metallic tube and other part of this lamp were left to reſt with their whole weight upon the tallow at the ring or contraction of the upper aperture. In this ſituation the lamp was lighted, and it burned for a conſiderable time with a bright clear flame, more uniformly intenſe than that of a candle, and ſuperior to the ordinary flame of a lamp in its colour and the perfect abſence of ſmell. After ſome minutes it began to decay, and ſoon afterwards went out. Upon examination it was found, that the metallic piece which covered the wick had fuſed a ſufficient quantity of tallow for the ſupply during the combuſtion; that part of this tallow had flowed beneath the ring, and to other remote parts of the apparatus, beyond the influence of the flame; in conſequence of which, the tube and the cylinder of tallow were faſtened together, and the expected progreſſion of ſupply prevented. In every lamp for burning conſiſtent oils, it ſeems probable, ſays Mr. Nicholſon (ubi infra,) that the materials ought to be ſo diſpoſed as to deſcend to the flame upon the principle of the fountain reſervoir. Although this conſtruction failed, a contrivance of a ſimilar nature would be of very great public utility. With regard to the ſecond object above ſpecified, Mr. Nicholſon is led by various conſiderations to imagine, that the ſpontaneous ſnuffing of candles made of tallow or other fuſible materials, will ſcarcely be effected but by the diſcovery of ſome material for the wick, which ſhall be voluminous enough to abſorb the tallow, and at the ſame time ſufficiently flexible to bend on one ſide. The moſt promiſing ſpeculation reſpecting this moſt uſeful article, ſeems to regard the cup which contains the melted tallow. This is apt to break down by fuſion, and thus to ſuffer its fluid contents to eſcape. The Chineſe have a kind of candle about half an inch in diameter, which, in the harbour of Canton, is called a "lobchock." The wick is of cotton, wrapped round a ſmall ſtick or match of the bamboo cane. The body of the candle is white tallow; but the external part to the thickneſs of about one thirtieth of an inch conſiſts of a waxy matter coloured red; this covering gives a conſiderable degree of ſolidity to the candle and prevents its guttering, becauſe it is leſs fuſible than the tallow itſelf. The ſtick in the middle might probably be of advantage in throwing up a leſs quantity of oil into the flame than would have been conveyed by a wick of cotton ſufficiently ſtout to have occupied its place unſupported in the axis of the candle. Mr. Nicholſon ſays that he formerly made a candle in imitation of the "lobchock." For this purpoſe he adapted the wick in the uſual pewter mould; he then poured in wax, which was immediately afterwards poured out; the film of wax, adhering to the inner ſurface of the mould, ſoon became cool; and the candle was completed by filling the mould with tallow. When it was drawn out, it was found to be cracked longitudinally on its ſurface, which he attributed to the contraction of the wax, by cooling, being greater than that of the tallow: or it might have been owing to the too ſudden cooling of the wax before the tallow was poured in. The experiment was not repeated. After all, the moſt deciſive remedy for the imperfection of this cheapeſt, and in other reſpects beſt material for candles, would undoubtedly be a diminution of its fuſibility: with this view Mr. Nicholſon made ſome experiments. The object is, in a commercial view, entitled to aſſiduous and extenſive inveſtigation. Chemiſts in general, ſuppoſe the hardneſs or leſs fuſibility of wax to ariſe from oxygen; and to this object attention ſhould be directed in the inquiry. Nicholſon's Firſt Principles of Chemiſtry, p. 517. Nicholſon's Journal, Vol. I. p. 70.

The Chineſe obtain from the tallow tree (*Croton ſebiferum*, Linn.) a kind of vegetable fat, with which they make a conſiderable proportion of their candles; which are firmer than thoſe of tallow, and free from all offenſive odour; but they are not equal to thoſe of wax, or ſpermaceti. Cheap candles are alſo made of tallow, and even of greaſe of too little conſiſtence to be uſed, without the contrivance of being coated with the firmer ſubſtance of the tallow tree or of wax. The ſurface of theſe candles is ſometimes painted red. Their wicks are made of different materials. For their lamps, they uſe the amianthus, which burns without being conſumable in fire, or the artemiſia, and carduus marœus, with which tinder is alſo made; but for candles, they uſe a light inflammable wood, in the lower extremity of which is pierced a ſmall tube to receive an iron pin, which is fixed on the flat top of the candleſtick, and thus ſupports the candle, without the neceſſity of a ſocket. The candle-makers at Munich have for ſeveral years paſt prepared tallow candles with wooden wicks, which afford about the ſame quantity of light as a wax candle, burn alſo with great ſteadineſs and uniformity, and never crack or run. Theſe wicks are formed of very thin ſlips of wood, bound round to a conſiderable thickneſs with very fine unſpun cotton, but ſuch that the ſize of the wick does not much exceed that of the wick of a common candle. The candle-makers either purchaſe or prepare for themſelves theſe ſlips of wood, which are ſomewhat ſquare and not completely rounded, and are made of pine, willow, and other kinds of wood, but moſt commonly of fir. Some take ſhoots of the pine-tree a year old, or common fir twigs of the ſame age, ſcrape off the bark, and reduce them to the ſize of a ſmall ſtraw; they then rub over theſe rods with wax or tallow, till they are covered with a thin coating of either of theſe ſubſtances; after which they roll them on a ſmooth table in a very fine carded cotton, drawn out to about the length of the rod or candle-mould. After this preparation the wick will have acquired the ſize of the barrel of a ſmall quill; and the more accurately the ſize of the wick is adapted to that of the candle-mould, ſo much the clearer and longer will the candle burn. Theſe wicks are then placed very exactly in the middle of the mould, and retained in that poſition; and good freſh tallow, previouſly melted with a little water, is then poured round them; but old and rancid tallow will not run if the wicks be properly made. Theſe candles not only burn longer than the common ones, but they do not flare, and they are leſs prejudicial to the eyes of thoſe who are accuſtomed to read or write at night. They muſt be ſnuffed with a pair of ſharp ſciſſars, and in doing this care muſt be taken not to damage or break the wick.

It has been ſuggeſted by Dr. Franklin, that the flame of two candles joined gives a much ſtronger light than both of them ſeparate. Probably the union of the two flames produces a greater degree of heat, by which the vapour is attenuated, and the particles of which light conſiſts more copiouſly emitted. Prieſtley's Hiſt. of Viſion, &c. p. 807. For a compariſon of the light of a candle with that of a lamp, ſee Lamp. For the method of eſtimating the intenſity of candle-light, &c. ſee Light and Photometer.

Dr. Ingenhouſz has deſcribed in the Philoſophical Tranſactions (vol. 68.) a method of lighting a candle by a ſmall electrical ſpark. For this purpoſe he uſes a ſmall phial, having 8 or 10 inches of metallic coating, or even leſs, charged with electricity; and the operation may be performed at any time of the night by a perſon, who has an electrical machine in his room. "When I have occaſion to light a candle," ſays he, "I charge a ſmall coated phial, whoſe knob is bent outwards, ſo as to hang a little over the body of the phial; then I wrap ſome looſe cotton over the extremity of a long braſs pin or a wire, ſo as to ſtick moderately faſt to its ſubſtance. I next roll this extremity of the pin wrapped up with cotton in ſome fine powder of reſin, which I always keep in readineſs upon the table for this purpoſe, either in a wide-mouthed phial or in a looſe paper; this being done, I apply the extremity of the pin or wire to the external coating of the charged phial, and bring as quickly as poſſible the other extremity wrapped round with cotton to the knob; the powder of reſin takes fire and communicates its flame to the cotton, and both together burn long enough to light a candle. As I do not want more than half a minute to light my candle in this way, I find it a readier method than kindling it by a flint and ſteel, or calling a ſervant. I have found, that powder of white or yellow reſin lights eaſier than that of brown. The "farina lycopodii" may be uſed for the ſame purpoſe; but it is not ſo good as the powder of reſin, becauſe it does not take fire quite ſo readily, requiring a ſtronger ſpark not to miſs; beſides, it is ſoon burnt away. By dipping the cotton in oil of turpentine, the ſame effect may be as readily obtained, if you take a jar ſomewhat greater in ſize. This oil will inflame ſo much the readier if you ſtrew a few fine particles of braſs upon it. The pin duſt is the beſt for this purpoſe; but as this oil is ſcattered about by the exploſion, and when kindled fills the room with much more ſmoke than the powder of reſin, I prefer the laſt."

For the method of lighting candles by phoſphoric tapers or matches, ſee Phosphorus.

Candle, a term ſometimes uſed in *Medicine* and *Surgery*. Thus, medicinal candles, *candelæ fumales*, are compoſitions of odoriferous, aromatic, and inflammable matters, as benzoin, ſtorax, olibanum, turpentine, and the like, mixed up with a third or more of the charcoal of willow or lime-tree, reduced to a proper conſiſtence with mucilage of tragacanth, and formed into maſſes in ſhape of candles. The *effluvia* and odours of theſe candles, when burnt, are ſuppoſed to be ſalutary to the breaſt, &c. For candles in ſurgery; ſee Bougie.

Candle, *corpſe*, *canwyll corph*, in Welſh, a name given to a light or flame, reſembling that of a candle, which, according to an opinion very commonly received in the dioceſe of St. David's in South Wales, proceeds from the houſe, and even ſometimes from the bed, where a ſick perſon lies a ſhort time before his death, and purſues its way to the church where the corpſe is to be interred, preciſely in the ſame track which the corpſe is afterwards to follow.

Candle, *ſale* or *auction by inch of*. See Inch *of Candle*. There is alſo a kind of excommunication by inch of candle; wherein the time a lighted candle continues burning is allowed the ſinner to come to repentance; but after which he remains excommunicated to all intents and purpoſes.

Candle-*berry tree*, in *Botany*, ſee Myrica *Cerifera*. For the wax of this tree, ſee Wax.

Candle *bombs*, denote ſmall glaſs bubbles, with a neck of ſlender bore about an inch long, through which a ſmall quantity of water is introduced, and the orifice is then cloſed up. When this ſtalk is applied to the wick of a burning candle, the flame ſoon rarefies the water into ſteam, the elaſticity of which breaks the glaſs with a loud exploſion.

Candle, *philoſophical*, or *candle of the chemiſts*, as it is ſometimes called, conſiſts of a bladder having its orifice furniſhed with a tube of metal ſome inches in length, and capable of being adapted to the neck of a bottle, containing a compoſition formed in the proportion of 3 ounces of oil or ſpirit of vitriol, and 12 ounces of common water, to which, when heated, is added an ounce or two of filings of iron. When the vapour or elaſtic air produced by the ſolution is diſcharged, apply the neck of the bottle to the orifice of the bladder, from which the air has been previouſly expelled by preſſure, and it will be filled with the elaſtic fluid produced by the diſſolution of the iron. When it is full, withdraw it, and apply to the orifice the flame of a torch, which will ſet fire to the vapour and cauſe it to burn ſlowly; and if the bladder be compreſſed, it will yield a fine flaming ſtream of a yellowiſh green colour.

Candles, *ruſh*, are made of the pith of a ſort of ruſhes, peeled or ſtripped of the ſkin, except on one ſide, and dipped in melted greaſe. Theſe are uſed among the poor in ſome parts of Great Britain.

Candle-*wood*, ſlips of pine about the thickneſs of the finger uſed in New England, and other colonies, to burn inſtead of candles, giving a very good light.

The French inhabitants of the iſland of Tortuga uſe ſlips of yellow ſantal wood for the ſame purpoſe, and under the ſame denomination of *bois de chandelle*, which yields a clear flame, though of a green colour. The nations of Otaheitee uſe, as a ſubſtitute for candles, the kernels of an oily nut annexed, one above another, to a ſkewer that paſſes through them; the nuts anſwer the purpoſe of tallow, and the ſkewer that of a wick.

CANDLEMAS, a feaſt of the church, held on the 2d of February, in memory of the Purification of the Bleſſed Virgin.

It takes its name either from the number of lighted candles uſed by the Romiſh church, in the proceſſions of this day; or becauſe, before maſs, the church conſecrated candles for the whole year. This ceremony was prohibited in England, by an order of the council in 1548.

Candlemas is alſo called, in ancient writers, *Hypapante*; and among the moderns, the *Purification*.

Some will have this feaſt to have been inſtituted by pope Gelaſius, in lieu of the heathen lupercalia; and that proceſſion was thereon made with lighted candles round the fields and grounds, by way of exorciſm. Hence Bede ſays, "It is happy for the church to have changed the luſtrations of the heathens, held in the month of February, around the fields, for the proceſſions with hallowed candles, in remembrance of that divine light wherewith Chriſt illuminated the world, whence he was ſtyled by Simeon, a *light to lighten the Gentiles*." Others aſcribe the origin of candlemas to pope Vigilius, in the year 536, and ſuppoſe it inſtituted for the feaſt of Proſerpine, held with burning tapers by the heathens in the beginning of February.

In Scotland, candlemas is one of the four terms of the year. See Term.

In England, this is no day in court, for the judges do not ſit; and it is the grand day in that term of all the inns of court, in which the judges anciently obſerved many ceremonies, and the ſocieties ſeemed to vie with each other in ſumptuous entertainments, accompanied with muſic and all kinds of diverſions.

Candlemas *Iſles*, in *Geography*, two iſlands in the South Pacific Ocean, diſcovered by captain Cook in 1775. S. lat. 57° 10'. W. long. 27° 13'.

Candlemas *Shoals* lie about 2° of latitude due N. of Port Praſlin (which ſee), and were diſcovered, named, and paſſed by Mendana, in 1569.

CANDLESTICK, a houſehold utenſil, contrived to hold one or more lighted candles. Larger and more ſtately candleſticks, contrived for holding a great number of candles, are called *branches*, and *girandoles*; and when made of glaſs, *luſtres*.

In the year 1800, Mr. Raybould, of London, obtained a patent for candleſticks on a new principle, which will admit and firmly hold candles of various ſizes. The candleſtick of his invention is a hollow pillar of metal as uſual; the candle is fixed into a ſocket compoſed of a broad circular ring, formed of two half cylinders cut down perpendicularly, and fixed in the ſame ſtand, ſo as to form a complete cylinder when joined together. Their approach to each other is regulated by a ſcrew, ſo that they may be preſſed upon a candle of any ſize, and will hold it firmly. The candle ſlides up and down the candleſtick by means of a ſmall knob which is fixed to the ſocket containing the candle, and projects on the outſide through a longitudinal ſlit in the candleſtick from the top to the bottom. The candle ſocket is kept up to any height by a ſpring which projects from its lower part, and preſſes on the outſide of the hollow pillar, which forms the ſtem of the candleſtick. *Fig*. 7, *Plate of Candle-making*, repreſents one of Mr. Echardt's patent candleſticks; it is calculated to ſet the candle at any height as it is conſumed: to accompliſh this the upper part A ſlides into that of B, and the part B ſlides up and down in that of C. In order that theſe ſlides may keep in the place they are ſet, the rim D, *fig*. 7, unſcrews, and is repreſented ſeparately in *fig*. 8. To the bottom of the rim is ſoldered a copper cylinder, which goes withinſide of the tube *c*; in three or four places on this cylinder an oblong piece of the metal F is cut out, except at the upper end; it is then bent inwards, to give it a ſufficient ſpring againſt the ſliders A, B, to ſteady it: this contrivance is the ſame as is uſed in ſliding teleſcope tubes. *Figs*. 9, 10, 11, and 12, repreſent different contrivances for making the nozle of the candleſtick fit different ſized candles; in *fig*. 9, the two leaves A, B, which compoſe the nozle, are ſo fixed to the part *c*, as to have a tendency to ſpring from each other; but they can be brought together to fit the candle, by ſliding the ring D upwards. In *fig*. 10, the two pieces of iron plate A, B, are incloſed in a common veſſel, and are riveted to it at *c*; they may be cloſed by the ſcrew D, and their own elaſticity opens them when the ſcrew is ſlackened. In *fig*. 11, the ſize of the nozle A is diminiſhed by three ſegments of a circle *a b*, and another not ſeen, which, when the rim B, on the outſide, is turned one way, they move into, and diminiſh the ſize of the nozle A; but when it is turned the other, they draw back fluſh with the inſide of the tube A. This is effected by the mechaniſm, repreſented in *fig*. 12, where *a*, *b*, *c*, are the ſegments moving on centres; on the inſide of the rim B, C, are three knobs *h*, *h*, *h*, which, when they are moved round one way, preſs on the projections *a*, *b*, *c*, on the long end of the ſegments, and move them into the cavity A; but when turned the other, they preſs the knobs on the ſhort end of the ſegments, and draw them back.

The *golden candleſtick* was the richeſt utenſil in the Jewiſh tabernacle. It was made of ſolid gold, and weighed a talent; and, according to Cumberland, the value of it, excluſive of the workmanſhip, was 5076 pounds. It contained ſeven lights, ſix branching out in three parts on each ſide of the upright ſtem, and one on the top of it. Each branch was adorned with cups, knobs, and flowers, alternate and equidiſtant; and on the top of each was fixed a lamp, in form of an almond, which might be put on or taken off occaſionally; and in theſe were put the oil and the wick, or the cotton, which was drawn in and out by tongs or ſnuffers; under them were ſnuff-diſhes for receiving the ſparks, or refuſe of the oil that fell from the lamps. This candleſtick was placed in the antichamber of the ſanctuary, on the ſouth ſide, and ſerved to illuminate the altar of perfume, and the tabernacle of the ſhew-bread: and it was the buſineſs of the prieſt to light the lamps every evening, at the time of incenſe, and to extinguiſh them at the ſame time every morning. In Solomon's temple there were ten golden candleſticks of the ſame form with that deſcribed by Moſes; five on the north, and five on the ſouth ſide of the holy place. But after the Babyloniſh captivity, the golden candleſtick was placed in the temple, as it had been before in the tabernacle of Moſes; and when the Temple was deſtroyed, it was depoſited in the Temple of Peace, built by Veſpaſian; and the repreſentation of it ſtill remains on the triumphal arch, at the foot of mount Palatine, on which Veſpaſian's triumph is delineated.

CANDLESTICK, *water*, a kind of jet or fountain raiſed on a foot which ſupports a little baſon reſembling the diſk of a candleſtick, down which the water falls into another larger baſon.

CANDO, CUNDI, or CONDI, in *Commerce*, a long meaſure uſed in ſeveral parts of the Eaſt Indies, particularly at Goa, the capital of the Portugueſe ſettlements there.

Silk and woollen ſtuffs are meaſured by the *varre*, and linen by the *cando*. The *cando* uſed in Pegu is equal to the Venetian ell.

CANDOLLEA, in *Botany*, a genus formed by Mirbel for ſome ſpecies ſeparated from *acroſtickum*.

Gen. Ch. Fructification diſpoſed regularly in dots: involucres lodged in ſmall cavities. It contains A. *heterophillum*, *lanceolatum*, and *polypodioides* of Linnæus, and A. *longifolium* of Burman, all natives of the Eaſt Indies. See ACROSTICHUM.

CANDUARRE *Corle*, in *Geography*, a diſtrict or county in the ſouth-eaſtern part of the iſland of Ceylon. See CEYLON.

CANDURA, a cape of the iſland of Rhodes, which forms with cape Tranquillo, the moſt conſiderable and the moſt ſouthern promontory of the iſland, a large open bay. A river alſo, bearing the ſame name, diſcharges itſelf into the ſea, in the vicinity of this cape, after watering the interior parts of the iſland.

CANDY, a very conſiderable province in the iſland of Ceylon, ſituate in the centre of the iſland, and formerly honoured with the royal reſidence. The king ſtill holds his court there; and though all the other provinces have been more or leſs encroached upon, no part of Candia has ever been reduced to permanent ſubjection under a foreign power. The European dominions, however, which lie towards the coaſt, completely encircle the territories of the king of Candy, that occupy the greater part of the interior of the iſland. But ſince the Candians have been driven by their invaders into the mountains of the interior, it has been their policy carefully to prevent any European from ſeeing thoſe objects which might tempt the avarice of his countrymen, or from obſerving the approaches by which an army could penetrate their mountains. If an European by any accident was carried into their territories, they took every precaution to prevent him from eſcaping; and the guards ſtationed every where at the approaches, as well as the wide and pathleſs woods which ſeparate the interior from the coaſt, rendered ſuch an attempt almoſt completely deſperate. The dominions of the native prince are cut off on all ſides from thoſe occupied by the Europeans, by almoſt impenetrable woods and mountains. The paſſes which lead through theſe to the coaſts are extremely ſteep and difficult, and ſcarcely known even to the natives themſelves. Beyond the woods and mountains the country preſents a ſcene widely differing in ſoil, climate, and appearance from that which lies within 10 or 20 miles from the ſea-coaſt; and it ſeems to have advanced but a few ſteps beyond the firſt ſtate of improvement, when compared with the highly cultivated fields, not far diſtant, which ſurround Columbo. The country gradually riſes toward the centre of the iſland, and the woods and mountains that ſeparate its ſeveral parts become more ſteep and impervious. In theſe faſtneſſes the native prince ſtill preſerves thoſe remains of territory and power, which have been left him by ſucceſſive invaders. His dominions are of courſe much reduced in ſize; for beſide the whole of the ſea-coaſts, which were of any value, the Dutch, in their various attacks during the laſt century, have contrived to get into their power every tract from which they could derive either emolument or ſecurity. Thoſe provinces which he ſtill retains are Noureculva and Hotcourly, towards the north and north-weſt; while Matuly, comprehending the diſtricts of Bintana, Velas, and Panoa, with a few others, occupies thoſe parts that lie more to the eaſtward. To the ſouth-eaſt lies Ouvah, a province of ſome note, which gives to the king one of his titles. The weſtern parts are chiefly included in the provinces of Cotemal and Hotteracorley. Theſe different provinces are ſubdivided into "corles," or diſtricts, and entirely belong to the native prince. In the higheſt and moſt centrical part of the native king's dominions lie the "corles," or counties of Oudanour and Tatanour, in which are ſituated the two principal cities. Theſe countries take the pre-eminence of the reſt, and are both better cultivated, and more populous than any of the other diſtricts; and they are diſtinguiſhed by the general name of "Condé Udda;" "condé," or "candé," in the native language ſignifying a mountain, and "udda" the greateſt or higheſt. This province of Condé Udda is even more inacceſſible than the others, and forms a kind of ſeparate kingdom of itſelf. On every ſide it is ſurrounded by lofty mountains covered with wood, and the paths that lead to it are little more than the tracts of wild beaſts. Guards are ſtationed all round it to prevent both entrance and eſcape. The chief cities are Candy, Digliggy Neur, and Nilemby Neur, which ſee. The ruins of other towns, apparently larger and better built, prove that the kingdom of the Candians was once in a more flouriſhing condition, and gradually tending, by the natural courſe of things, to civilization and opulence, when the invaſion of the Europeans deprived them of all thoſe means by which they could have acceſs to foreign nations, and an opportunity of importing either arts or manners into their own. In the northern part of the kingdom lies the province of Noure Calava, where may ſtill be diſcovered the ruins of the once famous and ſplendid city of Anurodgburro; ſtanding almoſt at the northern extremity of the Candian dominions, and bordering on the province of Jafnapatam. In former ages this was the reſidence of the kings of Ceylon, and has for a long time been the place of their burial. Tradition reports, that they reigned in regular ſucceſſion for 90 generations of the ſame family, from the time of the flood, and that they lived to a great age, like the ancient patriarchs. After their death they are ſuppoſed to have been carried up to heaven, and to have been ſince employed as tutelary deities to the inhabitants of the iſland. They were revered as deities, and all buried in a large temple, or tomb, near their ancient city of Anurodgburro, the remaining veſtiges of which indicate an uncommonly excellent architecture for the age in which it was erected. In the vicinity of this town ſtood formerly the ſtately temples and pagodas of the Ceyloneſe worſhip, as appears by the maſſy pillars and hewn ſtones which ſtill remain. The Portugueſe, when they became maſters of the town, ſacrilegiouſly deſtroyed its religious edifices, and tranſported the choiceſt materials to fortify Columbo and the other towns which they erected on the ſea-coaſts;—an act which the Ceyloneſe ſtill record with horror. The whole of the king's country, the plains around Anurodgburro excepted, preſent a conſtant interchange of ſteep mountains and low vallies. The exceſſive thickneſs of the woods, that cover the greateſt part of the country, occaſions heavy fogs and unwholeſome damps. The vallies are generally marſhy, and abounding with ſprings, which excellently adapt them to the cultivation of rice and the rearing of cattle. The inſalubrity of the climate, after the rainy ſeaſon, counteracts theſe advantages. The principal difference between the climate of the interior and that of the coaſts is occaſioned by the ſtagnation of the atmoſphere in the former. The depth of the vallies and the thickneſs of the woods concur in preventing the free circulation of the air; ſo that the night is conſtantly attended with very cold damps, which are ſucceeded by days equally noxious on account of their hot and ſultry vapours. Hence it happens, that an European on coming to the interior is very ſubject to the hill or jungle fever; a diſeaſe reſembling our ague and intermittent fever, accompanied with a violent dyſentery, which never leaves the perſon attacked till he removes to the ſea-coaſt, where the climate is more cool and refreſhing in the day, and more free from the cold and damps of the night. The country of Candy can never derive any improvement from internal navigation; as the ſeveral large rivers that interſect it are rendered, during the rainy ſeaſon, ſo rapid and impetuous by the torrents which fall into them from the ſurrounding hills, that no boat can venture upon them, while in the oppoſite they are almoſt completely dried up. Its largeſt rivers are the *Malivagonga* and *Mulivaddy*, which ſee. The rainy ſeaſon varies in different parts of the interior. The S.W. quarter is ſubject to the influence of the weſtern monſoons, while the N.E. is but ſlightly touched by thoſe from the oppoſite quarter. The high range of mountains that croſſes the country of Candy divides the iſland into two different climates; ſo that there has been a continued drought on one ſide of them for years, while it has rained on the other without intermiſſion. The eaſtern parts are leſs ſubject to the influence of the monſoons than thoſe to the weſt, and conſequently much leſs deluged with rains. Among the mountains of the interior, the ſeaſons do not exactly correſpond to either of the monſoons; and among them it rains inceſſantly in March and April, at which period it is dry in the low lands.

The diſpoſition and character of the Candians derive their caſt from their ſituation. Although they are ſubject to complete deſpotiſm, they are proud of being free from a foreign yoke, and of being ſlaves only to a maſter of their own race. They are in their air and aſpect grave and haughty, and regard with contempt the Cingleſe in our ſervice, as a mean deſpicable race, who barter their natural rights for peace and protection. Nevertheleſs, they are more courteous and polite, and at the ſame time more crafty and treacherous than their countrymen of the low-lands. They are alſo more athletic, and being accuſtomed from their infancy to bear arms, and to watch the different poſts where danger is apprehended, they acquire a military air, which diſtinguiſhes them from the Cingleſe. Their houſes are alſo neater and better built. The dreſs of the higher order of the Candians conſiſts of ſeveral folds of cotton cloth, or calico, drawn cloſe round their waiſts; while another piece, after being wrapped round the body, is tucked up at the back by one end, and by the other drawn together between the legs, or hanging down ſtraight to the ancles: their arms, ſhoulders, and cheſt are bare. On their heads they wear a ſort of turban, broad and flat at the top, narrow towards the lower part, and ſtiffened with "conjee," a ſpecies of ſtarch made of rice. Over their ſhoulders, or round their waiſts they wear a belt, to which a dagger or ſhort hanger is ſuſpended. Before them they wear a purſe, which holds betel-leaf, areka-nuts, and tobacco; and they are commonly attended by a boy, with an ivory or tortoiſe-ſhell box filled with theſe articles. They conſtantly uſe an umbrella of talipot-leaf when they walk abroad in the day. They all wear rings on their fingers; but are prohibited by royal authority from uſing them in their ears. The chief diſtinction, with regard to dreſs, between the higher order of the Candians and the Cingleſe, conſiſts in the form of the cap, and the immenſe quantity of cloth worn round the waiſt of the former. The dreſs of the lower orders among both is in every reſpect the ſame, the diſtinction of the cap excepted. The Candian men in general are better dreſſed than the Cingleſe, and alſo fairer in their complexion. The women are not eaſy of acceſs to the Europeans; but it is ſaid, that there is no material difference in the manners, appearance, or dreſs of the Candian and Cingleſe females.

The Candians are diſtributed into different claſſes, ſcrupulous of their reſpective precedence. The firſt claſs comprehends the nobles, who never contaminate their blood by intermarriage with perſons of an inferior rank. This claſs is known by the name of "Hondrews." The next rank includes artiſts, as painters, ſmiths, carpenters, and goldſmiths. Their dreſs is the ſame with that of the Hondrews, but they are not permitted to eat with the nobles, or to mix in their ſociety. Thoſe who are employed in the lower occupations, as they are deemed, of barbers, potters, waſhers, weavers, &c. form a third caſt, with which the common ſoldier ranks. The fourth caſt includes the peaſantry and labourers of all deſcriptions, who either cultivate the land for themſelves, or are forced to work for others. All theſe four caſts continue unmingled; the ſon purſuing the profeſſion of his father from generation to generation. Beſides theſe caſts, there is in Candia, as well as in other parts of India, another wretched claſs, conſiſting of ſuch, who by any crime or neglect of ſuperſtitious rites have, according to the decree of the prieſts, forfeited their caſt, and are condemned to infamy, pertaining to themſelves, and entailed on their deſcendants through all generations. None of any other caſt will intermarry with them; they are not allowed to exerciſe any trade or profeſſion, nor to hold intercourſe but with ſuch as themſelves; and if they accidentally touch any thing, it is reckoned polluted and accurſed. Not allowed to work, they are reduced to the neceſſity of begging for their ſubſiſtence. Theſe unhappy people are obliged to pay the loweſt of the Candians as much reverence as eaſtern ſervility ordains the latter to pay to their ſovereign.

The government of Candy is an abſolute deſpotiſm, and reſiſtance to the will of the king is attended with certain and immediate deſtruction. Nevertheleſs, the Candians hold in veneration fundamental laws of remote antiquity, the violation of which renders the ſovereign amenable to the juſtice of his country as well as the meaneſt ſubject. By theſe fundamental laws the monarchy is elective, and the people may ſet aſide the next branch of the royal family, and elect the more diſtant, or even a ſtranger; though the throne has been in general, for many ages, poſſeſſed by the ancient Candian royal family, which is now very nearly extinct. The king of Candy yields to no eaſtern prince in the number and extravagance of his titles, which it is needleſs to recount. They claim, however, from his ſubjects correſponding reverence. No one dares approach him without proſtrating himſelf three times before the throne, and at each act of proſtration reciting his titles. Perſons of the higheſt rank are prohibited from coughing or ſpitting in his preſence, and every one maintains before him inviolable ſilence. His progreſs, however, is always attended by a number of performers on various inſtruments, ſuch as tom-toms, or drums of various ſizes, ſhrill and ſqualling clarionets, pipes, flageolets, a ſort of bag-pipes, and pieces of braſs and iron jingled by way of triangles. Among other attendants of the monarch are people furniſhed with long whips, made of hemp, coya, graſs, or hair, with a thong or laſh 8 or 12 feet in length, without any handle; and whoſe buſineſs it is to run before the proceſſion with ſtrange geſtures, in order to clear the way, and to announce his majeſty's approach. As the government is deſpotic, all ſorts of promotion depend on the king's pleaſure; nevertheleſs, reſpect is uniformly manifeſted to the inſtitution of caſts, and officers of a certain rank muſt always be choſen out of a certain claſs. The king's regular troops, or ſtanding army, are always near his perſon, and do duty in the interior; while the defence of the frontiers is entruſted to the adjoining inhabitants, who form a ſort of militia, and watch over the entrances into the country. The higheſt officers of the ſtate are the "Adigars," or prime miniſters, two in number, who ſhare the whole power of the court. Theſe are uſually ſelected from oppoſite factions, and of different diſpoſitions, to prevent an union which might overwhelm the royal power. The adigars are the ſupreme judges of the realm; before them all cauſes are brought, and they pronounce final judgment; though from their ſentence an appeal, ſeldom of any avail, lies to the king himſelf. The diſtinguiſhing badge of the adigars conſiſts of a certain number of officers, who compoſe their train, and who carry a ſort of ſtaves, and a ſeal of hard clay, indicating the king's commiſſion, and never failing to command obedience to any mandate that is iſſued. The embaſſies to the European government at Columbo are entruſted to theſe prime miniſters; and they are alſo charged with the reception of our ambaſſadors. Next in rank to the adigars are the "Diſſauvas," who are the governors of the "corles," or diſtricts, and alſo the principal military commanders: they attend the king's perſon, collect the revenues, and maintain order and diſcipline. But though they poſſeſs great authority, as well as the other officers of ſtate, none of them are allowed to puniſh capitally without the cognizance of the king, whoſe excluſive prerogative it is to pronounce ſentence of death. The diſſauvas, whilſt they retain their office, are allowed by the king a certain portion of land for their ſervices; but under pretence of collecting contributions for their royal maſter, they are chargeable with grievous oppreſſion. Subordinate to theſe are inferior officers reſident in the ſeveral diſtricts in which they are appointed, as their ſuperiors generally reſide at court and attend the perſon of the king. To theſe again there is another inferior rank of officers, who fulfil the duties of conſtables and police officers. The whole plan of government forms a regular ſyſtem of oppreſſion, which is ſeverely felt by the lower orders of the people, whoſe property is wholly at the mercy of the rapacious officers of the court.

The principal revenues of the king ariſe from preſents or contributions brought him by the people, or rather irregularly enforced by his officers, two or three times a year. Theſe contributions conſiſt of money, precious ſtones, ivory, cloth, corn, fruit, honey, wax, arms, and other articles of their own manufacture, as ſpears, arrows, pikes, targets, talipot-leaves, &c. The oppreſſion principally experienced by the lower claſſes of the people is alſo extended to perſons of ſuperior rank. On certain feſtivals obſerved in great ſtate, all the "Mahondrews" and principal people are required to attend, and none muſt approach the royal preſence empty-handed. After depoſiting their preſents at the palace-gate they are admitted into the preſence of the king, and received according to the value of their offering. Beſides theſe ſtated modes of extortion, there are others no leſs oppreſſive. Any perſon who is known to poſſeſs any articles of value is required to impart a portion to the royal treaſury; and artiſts are frequently employed by the king to manufacture for him arms and different articles in ſilver and gold, altogether at their own expence. All the Candians are obliged to take arms without diſtinction at the command of the ſovereign. His regular troops, as they are called, may conſiſt of about 20,000 men. Like other deſpots who are afraid to truſt their own ſubjects, the king always keeps about his perſon a body of Malabars, Malays, and others who are not his own natural ſubjects. In theſe he repoſes his chief confidence, and he employs them as his conſtant body-guard. Beſide this corps of foreign guards, who do perpetual duty at the royal palace, about 8000 of his regular troops and a number of the nobles are quartered in the neighbourhood, ready to be aſſembled at a moment's notice. The reſt of the military force lies ſcattered through the country. Their pay and ſubſiſtence conſiſt of a ſmall allowance of rice and ſalt, a piece of cloth annually given for their dreſs, and an exemption from taxes and all other ſervices, and a ſmall piece of ground which they cultivate for their maintenance. The uſual military puniſhment is compulſion to level a piece of hill, or clear the channel of a river. For more trivial offences the ſoldiers are curtailed of their pay and allowances. Diſtruſt and jealouſy, the conſtant attendants of arbitrary power, pervade the whole military ſyſtem. Officers are encouraged by the king to act as ſpies againſt each other, and they are forbidden to correſpond, or even to ſee each other, except at times when public exigency requires their being aſſembled. They are chiefly prevented from forming any intercourſe or combination with Europeans; and for this purpoſe a continued chain of poſts and watches is eſtabliſhed around all the outſkirts of his dominions. This ſyſtem of vigilance is ſo ſtrictly obſerved, that no one is permitted to paſs from one diſtrict to another without examination and a paſſport, bearing different impreſſions according to the profeſſion of the bearer. The natives univerſally travel on foot; riding on horſeback being a royal privilege, ſeldom uſed by the monarch himſelf. No horſes indeed are kept in the interior except thoſe belonging to his majeſty: nor are any horſes reared in the interior. The Candians have no fixed and eſtabliſhed laws; though they boaſt of an ancient code, which remains in the hands of the king, who is its ſole interpreter. His authority ſuperſedes every other deciſion. The trials of the Candians are ſummary; and their puniſhments, unleſs the king interpoſes, immediate. Their capital puniſhments are always attended with ſome circumſtances of aggravation; ſuch as having the criminal daſhed to pieces by elephants, pounding him in a large mortar, or impaling him on a ſtake. Impriſonment is a ſpecies of puniſhment never inflicted on a Candian; and every ſpecies of confinement conveys ideas peculiarly horrible to their imagination. The great ſafe-guard of juſtice among the Candians is the natural mildneſs and honeſty of their diſpoſitions, in which they excel all other Indians. The Candians, precluded from intercourſe with foreign countries, and proud of immemorial independence, might be ſuppoſed to enjoy amidſt their native mountains and woods, a life of tranquillity and happineſs, not to be found among thoſe buſy nations, that are inflamed by luxury and agitated with the thirſt of gain. But this is far from being the caſe. The oppreſſion of their governors, the conſtant dread of Europeans, and the ſuperſtitious fears ariſing from the nature of their climate, by which they are continually haunted, deprive this iſolated people of all the enjoyments which ſeem congenial to their ſituation. Much of the gloom that overhangs the minds of the Candians originated with the oppreſſive exactions and deſtructive inroads of the Dutch. It is to be hoped, ſays Captain Percival, that our countrymen, by a generous and well regulated policy, will ſpeedily diminiſh their ſources of unhappineſs.

Percival's Account of the Iſland of Ceylon, 4to. 1805. See CEYLON.

CANDY, the capital of the king of Candy's dominions and the royal reſidence, is ſituated in the diſtrict of Tatanour, in the midſt of lofty and ſteep hills covered with thick jungle. The narrow and difficult paſſes, by which it is approached, are interſected with thick hedges of thorn; and hedges of the ſame ſort are drawn round the hills in the vicinity of Candy, like lines of circumvallation. The only paſſage through theſe is by gates of the ſame materials, called by the natives "Caravetties," and ſo contrived as to be drawn up and let down by ropes. When the Candians are obliged to retreat within theſe barriers, they cut the ropes, and then it is impoſſible to force a paſſage except by burning down the gates, which, from their green ſtate, and the conſtant annoyance of the enemy, would prove an enterpriſe of ſome time and difficulty. Theſe hedge-rows form the chief fortifications of Candy. The river Malivagonga alſo nearly ſurrounds the hill on which it ſtands: the river is here broad, rocky, and rapid; a very ſtrict guard is kept on it, and every one who paſſes or repaſſes is cloſely watched and examined. Although the caravetty neareſt Candy has a rampart or breaſt-work, on which ſome of their artillery is occaſionally mounted, it could make but a feeble reſiſtance to the approach of a regular army; ſo that Candy is indebted for its principal fortifications to nature. The city itſelf is a mean and miſerable place, ſurrounded by a mud wall of no ſtrength. Our chief knowledge of this city is derived from the embaſſy of general Macdowal, deputed to the king of Candy by governor North, in the year 1800, of which captain Percival has given a journal, in an appendix to his account of Ceylon: but the information thus obtained muſt neceſſarily be imperfect; as the ambaſſador and his ſuite were admitted only by torch-light, and always retired before break of day. From what they could obſerve the city conſiſts of a long ſtraggling ſtreet built on the declivity of a hill, about two miles long, with leſſer ſtreets branching off on both ſides: the houſes were mean and low, chiefly of mud, but their foundations were raiſed about 5 feet above the level of the ſtreet, ſo that they appeared lofty to paſſengers. The reaſon of this mode of conſtruction is to enable the king to hold his aſſemblies of the people, and to have his elephant or buffalo fights in the ſtreet without interfering with the houſes. Some of the houſes at the upper end of the ſtreet, belonging to the principal inhabitants, are tiled and white-waſhed. When the king paſſes along the ſtreet, none of the inhabitants are allowed to appear before their houſes or in the paths on a level with them, as this would be attended with the heinous indecorum of placing a ſubject higher than the prince deſcended of the ſun. At the upper end of this ſtreet ſtands the palace, built of a kind of cheenan or cement perfectly white, and containing a great number of rooms, the walls of which are painted in a grotesque manner, and covered with inſcriptions: in one room is a gigantic figure of braſs of Buddou in a ſitting poſture, with two ſmaller ones at his feet. The palace is ſurrounded with high ſtone walls, conſiſting of two ſquares, one within the other. In the inner of theſe, to which there is acceſs by a large arched gateway, are the royal apartments, where the court is held, and audiences are given. The hall of audience, or ſtate-room, is a long viranda, with alternate arches and pillars along its ſides, ſomewhat reſembling the aiſle of a church. At the farther end of this hall is placed a kind of platform or throne, covered with a carpet and ſurrounded with ſteps, where the king ſits in ſtate. His feet, and the lower part of his body are concealed from view by a ſmall partition in front. On occaſion of general Macdowal's reception, the courtiers were ſeen below the arches on each ſide of the hall, ſome proſtrate, others ſitting in ſilence and croſs-legged. The king was dreſſed in a robe of fine muſlin, embroidered with gold, drawn cloſe in ſeveral folds round the waiſt, and flowing from thence down like a lady's gown. His arms were bare from the elbows downwards. On his fingers were many broad rings ſet with precious ſtones of different ſorts, and a number of gold-chains were ſuſpended round his neck over a ſtiff frilled piece of muſlin reſembling Queen Elizabeth's ruff. His head was covered with a turban of muſlin ſpangled with gold, and ſurmounted by a crown of gold, by which he is diſtinguiſhed from all the other Aſiatic princes. Round his waiſt was a rich ſaſh, from which was ſuſpended a ſhort curved dagger or ſabre, with the handle richly ornamented, and the ſcabbard of gold fillagree-work. During the conference, which laſted three hours, roſe-water was frequently ſprinkled round from curiouſly wrought veſſels of gold; and perfumes were handed about on ſalvers of gold and ſilver fillagree-work. To one propoſal made on this occaſion, viz. that leave might be given to make a road, and to open a communication from Trincomalee to Columbo through the territories of the king a little north of Candy, he peremptorily refuſed to accede; but he expreſſed his decided averſion from any intercourſe or connexion exiſting between his ſubjects and the Europeans; profeſſing at the ſame time a deſire to live on amicable terms with the Britiſh, whoſe power he acknowledged to be far ſuperior to that of the Dutch. On January 31ſt, 1803, general Macdowal began his march with a conſiderable force into the Candian territory, and on the 20th of February, after encountering many difficulties, arrived at Candy. The king and his chief adigar precipitately withdrew, after having ſet fire to the palace and the temples. The Britiſh troops ſoon extinguiſhed the fire, and took poſſeſſion of the city. Although the Candians ſoon afterwards appeared in conſiderable force, they were quickly diſperſed after a dreadful ſlaughter. Before the Britiſh general left Candy, he adopted various meaſures to ſecure his new conqueſts. After ſome time, viz. in June, 1803, when it was thought tranquillity was eſtabliſhed, and in the midſt of a truce, Candy was attacked by the natives under the command of the firſt adigar; and the commanding officer, whoſe troops were become unfit for duty by the ſickneſs that prevailed among them, was under a neceſſity of capitulating, and of evacuating the fort, under a ſolemn ſtipulation that the garriſon ſhould be allowed to proceed, with arms and ammunition, and without moleſtation to Trincomalee, and that the ſick ſhould alſo be taken care of. In defiance of this agreement, after the commanding officer left the fort, all the Engliſh ſoldiers who accompanied him were treacherouſly murdered. Shortly after this maſſacre, the king of Candy, finding that the Britiſh force on the iſland was weak, determined to attack our forts on the coaſt; but all his efforts were ineffectual; and the Britiſh ſettlements were ſoon reſtored to ſecurity. Candy, or Kandi, lies in the centre of the country, 80 miles diſtant from Columbo, and about 160 miles from Trincomalee. N. lat. 7° 18′. E. long. 80° 46′.

CANDY, in ſpeaking of *Sugar*, denotes a preparation of that ſubſtance, made by melting, and cryſtallizing it ſix or ſeven times over, to render it hard and tranſparent. See SUGAR.

CANDY-*tuft*, in *Botany*. See IBERIS.

CANDYBA, in *Ancient Geography*, one of the moſt conſiderable towns of Aſia Minor in Lycia, which, according to Steph. Byz. derived its name from Candybus, ſon of Deucalion.

CANDYING, denotes an operation in *Pharmacy*, as well as *Confectionary*: thoſe ſimples which are preſerved in ſubſtance by boiling in ſugar being ſaid to be *candied:* though the performance of it is now transferred to the confectioner from the apothecary, to whom it originally belonged.

CANDYS, in *Ancient Geography*, a town of Aſia; in Media. Ptolemy.

CANE, in *Botany*. See Arundo *Bambos*, or *Bamboo.*

Cane, *ſugar*. See Saccharum.

Cane, in *Commerce*, the ſame with reed, called among botaniſts arundo, which ſee.

Canes make a conſiderable article in commerce. There are imported two ſorts, viz. *walking* and *rattan canes*.

Canes, *walking*, are ſaid by Bradley to be joints of the roots of a ſort of reed, called *canna Indica.* This plant ſhoots in joints of about three or four feet long, near the ſurface of the ground, and at every knot produces great numbers of fibres, by which it receives its nouriſhment. The joints are made ſtraight by the fire, which occaſions thoſe ſhades or clouds frequently ſeen in them. Bradley thinks the cane-tree might be propagated here by planting ſome of the roots with their knots in artificial bogs, &c.

Canes may be ſtained like tortoiſe-ſhell, by a mixture of aqua fortis and oil of vitriol laid on them at ſeveral times over live coals, to cauſe it to penetrate the deeper, and afterwards giving them a gloſs with a little ſoft wax, and a dry cloth. Boyle.

Canes, *rattan*, are a ſmaller ſort brought from China, Japan, and Sumatra, very tough; which being ſplit, are uſed for making of cane chairs. They are the produce of a reed called *rattang Malabarica minor*, or leſſer rattan. The ſpecific name is rotang, whence rattan, and in the Malayan language ſignifies a ſtaff or walking ſtick. Theſe when dry, being ſtruck againſt each other, will give fire, and are uſed accordingly in ſome places in lieu of flint and ſteel. Being twiſted together they make cordage of them. The Chineſe and Japaneſe veſſels are ſaid to have their cables made of them, which are leſs liable to rot in the water than hemp. Phil. Tranſ. N° 244, p. 326, and N° 267, p. 717. See Calamus.

The canes, or canas, in the juriſdiction of Guayaquil in South America, are remarkable for both their length and thickneſs, and the water contained in their tubes. Their uſual length is between 6 and 8 toiſes; and the largeſt do not exceed 6 inches in diameter. The wood or ſide of the tube is about 6 lines in diameter; ſo that when the cane is opened, it forms a board near $1\frac{1}{2}$ foot in breadth; and, therefore, it will not appear ſtrange that houſes ſhould be conſtructed of ſuch materials. From the time of their firſt appearance, till they attain their full perfection, when they are either cut down, or of themſelves begin to dry, moſt of their tubes contain a quantity of water, with this remarkable difference, that at full moon they are entirely, or very nearly, full, and with the decreaſe of the moon, the water ebbs, till at the conjunction little or none is to be found. During its decreaſe, the water appears turbid; but about the time of full moon, it is clear as cryſtal. The water is found to be an excellent preſervative againſt the ill conſequence of any bruiſes; at leaſt it is drunk by all who come from the mountains, where ſuch accidents are unavoidable. The canes, being cut, are left to dry, or, as they ſay, to be cured; whence they acquire ſuch a degree of ſtrength, that they ſerve for rafters, beams, floorings, or even maſts for balzas. Ships which load with cacoa are alſo cieled with them, to preſerve the timber from the great heat of that fruit. They are alſo uſed as poles for litters, and in a variety of other ways. Juan and De Ulloa's voyage to South America, by Adams, vol. i. p. 209.

Cane, *fiſhing-rod*. See Reed.

Cane, *Indian*. See Canna.

Cane-*apple*, in *Natural Hiſtory*, a name given by the common people of Ireland to the *arbutus*, or ſtrawberry-tree. See Arbutus.

Cane, Canna, a long meaſure, frequent in Italy, Spain, and the ſouth parts of France; of greater or leſs length, according to the places where it is uſed. It is called by the Latins *calamus*, and in ſcripture a *reed*.

At Naples, the canna is equal to ſeven feet $3\frac{1}{2}$ inches, Engliſh meaſure; the canna of Thoulouſe, and the Upper Languedoc, is equal to the *vara* of Arragon, and contains five feet $8\frac{3}{4}$ inches; at Montpellier, in Provence, Dauphiné, and the Lower Languedoc, to ſix Engliſh feet $5\frac{1}{2}$ inches.

Cane, in *Ancient Geography*, a port-town of Arabia Felix, attributed by Ptolemy to the Adramites, who formed a claſs of the Sabæans.—Alſo, a promontory near this town, on the Red Sea.—Alſo, a promontory of Aſia minor, near the Caicus.

Cane, in *Geography*, a river of Hindooſtan, which runs into the Jumnah, 20 miles S.E. of Corah.

Cane, in *Rural Economy*, a term ſometimes uſed to ſignify a hollow place where water ſtands. It alſo implies a wood of alder, or other aquatic trees, in a moiſt boggy ſituation.

CANEA, in *Geography*, a maritime town of the iſland of Candia, or Crete, ſituate at the eaſtern extremity of a large bay, on the north ſide of the iſland, and ſuppoſed to have been built on the ſite of Cydonia, a flouriſhing city of ancient Crete, although no veſtige of ancient edifices be now perceived. Canea, after reſiſting the efforts of the Ottoman army conſiſting of 60,000 men for 50 days, during which ſiege the Turks are ſaid to have loſt 25,000, was compelled to capitulate in the year 1645. Although it is much leſs extenſive than Candia, the capital, it is the moſt populous and the moſt trading town of the whole iſland. In this place are reckoned upwards of 4000 Turks, 2 or 3 thouſand Greeks, 150 Jews, 4 French houſes, and ſome Italian houſes, which latter are under the protection of the emperor of Germany, or the republic of Raguſa. The form of its buildings reſembles that of the houſes of the Eaſt: in lieu of roofs, inclined and forming a ridge, they have a flat covering without tiles or ſlates, and conſtituting a terrace: moſt of them have only one ſtory. The ſtreets are laid out by the line; ſome of them are tolerably wide; in the public ſquares are fountains that flow with an abundant ſtream. The town is ſurrounded by a ſtrong wall and a wide ditch. It has but one gate on the land ſide. The harbour is defended by batteries in a good condition. To the left, on entering, is ſeen a jetty parallel to the coaſt, behind which a conſiderable number of veſſels might anchor if the bottom were cleanſed. The largeſt are obliged to remain near the entrance of the harbour, expoſed to the waves of a rough ſea when the northerly winds blow with violence. If during theſe northerly gales, they happen to have run into it, it is not poſſible for them to get out; but they are obliged to ſteer for the very narrow mouth of the harbour, where the waves riſe in heaps and frequently ſo high as to clear the mole, and to ſpread and break in the baſon. This baſon, through the negligence of the Turks, is choked up: it can ſcarcely admit veſſels of 200 tons burden: the arſenal and fine docks which the Venetians had conſtructed oppoſite to the jetty are falling into ruins and unfit for uſe. In the environs of Canea, there are ſome beautiful plains that are tolerably fertile and almoſt entirely cultivated; and they preſent to view gardens of orange-trees, foreſts of olive-trees, a few ſcattered vineyards, and fields appropriate to the culture of wheat, barley, cotton, ſeſamum, maize, melons, and different legumes. On the weſt of the town, beyond the little deſert iſland of *San Theodoro*, on which the Venetians had erected a battery for preventing a deſcent on the beach, is ſituate Platania, an extenſive, ſolitary, and rural walk, where grow ſpontaneouſly plane trees that excite aſtoniſhment by their ſize and number. Each of theſe ſupports one or two vine-plants, which embrace the whole compaſs of the tree, and furniſh in abundance, without care or culture, grapes with large ſtones of an excellent quality. A ſmall river alſo traverſes and waters this agreeable foreſt. The banks of the rivulets in the vicinity of Canea are commonly covered with oleanders and myrtles; and a great variety of trees bearing fruit, and of plants perfuming the air with their flowers, render the environs of this town peculiarly pleaſant and inviting.. The famous fraxinella or dittany of Crete, celebrated by the ancients, profuſely clothes the rocks in the neighbourhood. It is collected by the peaſants and formed into ſmall bundles, and brought to the markets of Canea and other towns, where it is much eſteemed for its permanent odour and other virtues that are aſcribed to it. But the moſt uſeful productions, and thoſe which yield the chief revenue of the town and pachalik of Canea, are the olive-trees, that yield a great quantity of fruit, from which is expreſſed an oil, forming an important branch of the commerce of Candia; although it is here badly manufactured: the inhabitants being ignorant of the art of refining it, and rendering it agreeable to the taſte. It is purchaſed by the Europeans only for their ſoap-houſes and manufactories. At Canea there are 20 ſoap houſes, which employ the oils of the provinces of Kiſſamos, Selino, and Cidonia; and theſe are ſo plentiful, that the French houſes eſtabliſhed in this town diſpatched to Marſeilles, during the year of the gathering and the following, to the value of from one to two millions of French livres. About a quarter of a league to the eaſt of Canea is a riſing ground, leading to calcareous hills, which advance into the ſea and form a peninſula terminated by Cape *Melecca*. Among theſe hills on a beautiful ſituation lies the monaſtery of the "Trinity," which is inhabited by a great number of friars, all of whom almoſt apply themſelves to the culture of the land. In the environs of the monaſtery are ſome ſuperb orchards of olive-trees, a few vineyards, and fields deſtined to the cultivation of different ſpecies of corn. Here are alſo many bees and a great number of goats and ſheep. In the garden was ſeen a ricinus or palma Chriſti planted twelve years ago, which indicated by its vigour that moſt of the plants of the warmeſt climates might be introduced into this iſland. Further towards the cape lies the monaſtery of "St. John." In the vicinity of Canea are huts erected for the accommodation of perſons infected with the leproſy, who are prohibited from all intercourſe with healthful perſons, and who ſubſiſt on the produce of a ſmall garden adjoining to their cottage, or poultry they rear, and on the alms of paſſengers. On the edge alſo of the road that leads to the only gate which Canea has on the land ſide, are expoſed the bodies of criminals, who have undergone the terrible puniſhment of empalement. They are ranged on each ſide of the road; and in this dreadful rank are ſeen men whoſe bodies are longitudinally tranſpierced by a ſtake, ſome dead, others expiring: ſome ſmoking their pipe with as much ſangfroid as if they were ſitting on cuſhions, railing at the Europeans, and living as long as 24 hours, in the moſt excruciating torments. In a field near Canea, Sonnini witneſſed the dance, mingled with ſinging, called "Romeca" which the preſent Greeks have received from their anceſtors, and which they have preſerved nearly with all its appendages. Canea is about 70 miles W. of Candia. N. lat. 35° 28'. E. long. 24° 15'.

CANEBEUM, in *Ancient Geography*, a town of Aſia Minor in Caria, mentioned by Steph. Byz. who ſays, that it was alſo called *Cyon*.

CANEFIELD, in *Geography*, a town of North America, in the ſtate of South Carolina; 6 miles N.N.W. of Queenborough.

CANELLA, in *Botany*. Murray Syſt. Veg. 443. Schreb. 817. Willd. 942. Gært. 486. Vent. 3. p. 160. (Winterania, Linn. gen. 598. Juſſ. p. 263. Winterana, Lam. Illuſt. pl. 399. Venterane, Boſ. nouv. dict.) Gen. Ch. *Cal.* one-leafed, deeply divided into three lobes; lobes roundiſh, concave, permanent. *Cor.* Petals five, longer than the calyx, oblong; nectary pitcher-ſhaped, the length of the petals. *Stam.* Filaments none; anthers twenty-one; (ſixteen, Schreb. from 12 to 20. Gært.) linear, parallel, adhering longitudinally to the outſide of the nectary. *Piſt.* Germ. ſuperior, within the nectary, egg-ſhaped, three-celled; ſtyle cylindrical, the length of the nectary; ſtigmas two or three, blunt, convex, wrinkled. *Berry* three-celled, one or two of the cells generally abortive. *Seeds* two, roundiſh-kidney-ſhaped. Eſſ. Ch. Calyx three-lobed. Corolla five petalled; anthers adhering to a pitcher-ſhaped nectary. Berry three-celled.

Sp. C. *alba*. Cluſ. exot. lib. 4. cap. 4. Swartz in Linn. Tranſac. vol. i. tab. 8. Woodville Med. Bot. p. 318. tab. 117. (C. peruana, and C. tubis minoribus alba, Bauh. pin. p. 409. 2, 3, and 4. Park theat. 1581. C. cubane, Johnſ. dendr. 165. C. cinnamomea, Pluk. phyt. tab. 160. f. 7. C. winterana, Gært. fruct. tab. 77. fig. 2.) A tree. *Stem* from 10 to 50 feet high, ſtraight, branched only at the top; bark whitiſh; branches erect, not ſpreading. *Leaves* petioled, alternate, but not regularly, oblong, acuminate, entire, thick, dark green, ſhining. *Flowers* in terminal, compound corymbs, violet, ſmall, ſeldom opening; lobes of the calyx roundiſh, concave, incumbent, ſmooth, membranous; petals concave, erect, thick, deciduous. *Berry* globular, fleſhy, ſmooth, black. *Seeds* fixed to the central angle of the cells, regularly two in each cell, but one or two cells are generally abortive, and ſometimes only one diſcernible, of different ſhapes, according to the number of abortive germs and cells, always black, ſmooth, and ſhining. Swartz and Gært. The whole tree is very aromatic, and when it is in bloſſom perfumes the whole neighbourhood. The flowers dried and ſoftened again in warm water have a fragrant odour, nearly approaching to that of muſk. The leaves have a ſtrong ſmell of laurel. The berries have a faint aromatic taſte and ſmell, and are greedily eaten by the white-bellied and bald-pate pigeons (*Columba jamaicenſis* and *leucocephala*), who acquire from them that peculiar flavour which is ſo much admired. Its bark, which in taſte is moderately warm, aromatic, and bitteriſh, and has an agreeable ſmell, reſembling that of cloves, was formerly a common ingredient in the food and drink of the Caraibs, and at preſent is a neceſſary addition to the meagre pot of the negroes. It is brought to Europe in long quills, which are about three quarters of an inch in diameter, ſomewhat thicker than cinnamum, and both externally and internally of a whitiſh or light brown colour, with a yellowiſh hue, and commonly intermixed with thicker pieces, which are probably obtained from the trunk of the tree. Its virtues are extracted moſt powerfully by proof ſpirit. It has long ſuperſeded the uſe of the Cortex winteranus, with which it was confounded, firſt by John Bauhin, and afterwards by Linnæus, who, in the firſt edition of the Species Plantarum, united the two plants under the name of *laurus winterana*, but in the enſuing editions made it a diſtinct genus, and called it *winterania.* The true codex winteranus brought by captain Winter from the ſtraits of Magellan in the latter end of the 16th century, and deſcribed by Cluſius, was, in conſequence of this miſtake, very rare, and imperfectly known in Europe for nearly a century, but has been recently brought again to light by the late Dr. Fothergill, with the aſſiſtance of the late Dr. Solander. See WINTERA *aromatica.*

The bark of canella alba, which has been received into the London and Edinburgh Pharmacopœias, inſteadof the old bark of Winter, has been ſuppoſed to poſſeſs conſiderable medicinal virtues, and to be an uſeful medicine in the ſcurvy and ſome other complaints; but is now conſidered merely as an aromatic, and is chiefly employed for the purpoſe of correcting, and rendering leſs diſagreeable, the more powerful and nauſeous drugs. It is, therefore, an ingredient in the Pulv. Aloet. Pharm. Lond. and in the Tinctura amara, Vinum amarum, Vinum rhei, &c. of the Pharm. Edinb. See Swartz's Botanical Hiſtory of the Canella Alba, in the Tranſactions of the Linnæan Society, vol. i. p. 96. t. 2. p. 318. and Woodville's Medical Botany, vol. ii. p. 318. This tree is too tender to live in England out of a ſtove. It may be raiſed from freſh ſeeds procured from the Weſt Indies, but is not readily propagated either by layers or cuttings.

CANELLA, in *Geography*, formerly called the *kingdom of Cota*, a large diſtrict of the iſland of Ceylon, containing a great number of cantons, principally occupied by the Dutch, and famous for the quantity of cinnamon, which it produces. It has ſeveral towns, forts, and harbours, on the coaſt. The interior is inhabited by the natives, and it has rich mines of rubies, ſapphires, topazes, cats-eyes, and other precious ſtones.

CANELLA *Alba*. The canella of the Materia Medica, is the inner bark of the *canella*, (which ſee) a very common tree in the Weſt Indies. This bark is brought over in long quills, much thicker than cinnamon, ſmooth, and brittle, and of a white or whitiſh yellow colour. To the taſte it is extremely pungent, and ſomewhat bitter, and is not very grateful. It yields its ſenſible qualities both to water and ſpirit, and has the common chemical characters of all the aromatic barks On account of its extreme pungency it is ſeldom uſed.

CANELLI, a town of Piedmont, in the county of Aſti; 12 miles S.S.E. of Aſti.

CANELOS, a town of Portugal, in the province of Tra-los-Montes; 5 miles N.N.E. of Lamego.

CANEM, or KANEM, a name ſometimes given to the country of Africa, called *Bornou*, which ſee. See alſo KANEM.

CANENTELOS, or CARANTONUS, *Charento*, in *Ancient Geography*, a river of Gallia Aquitaniæ. Ptolemy.

CANENTES, in *Natural Hiſtory*, a name uſed by ſome of the older writers for a ſpecies of foſſil ſhell not known to us in its recent ſtate, but deſcribed by Klein under the name of the *tubulus marinus concameratus*, and by other of the late authors under thoſe of *polythalamium* and *orthoceratites*.

CANEPHORÆ, Κανηφοροι, from κανης, *a reed*, and φερω, *I bear*, in *Antiquity*, were two virgins of quality at Athens kept in Minerva's temple in the Acropolis, who at the feaſt of the Panathenæa, carried baſkets on their heads with ſomething ſecret or myſterious therein, and delivered to them by the prieſteſs. The baſkets were uſually crowned with flowers, myrtles, &c.—The canephoræ, in theſe ceremonies, always marched the firſt, the prieſt next, and the choir of muſic followed.

The learned are at variance about the contents of the baſkets borne by the canephoræ. Some will have it, that neither they, nor the prieſteſs herſelf, knew what was in them. Others conjecture that they contained the things neceſſary for ſacrifice, &c.

There were alſo canephoræ in the ceremonies of Ceres and Bacchus. Thoſe in the Bacchanalia carried golden baſkets, in which were divers ſorts of firſt fruits, &c. Among ancient monuments, we find mention of divers figures of canephoræ. In that famous cornelian, called Michael Angelo's ring, there are three canephoræ with their baſkets on their heads.

The appellation canephoræ was alſo given to virgins at Athens, when becoming marriageable, they preſented certain baſkets full of little curioſities to Diana, in order to procure leave to quit her train, and change their ſtate of life.

CANEPHORIA was a ceremony, which made part of a feaſt celebrated by the Athenian virgins on the eve of their marriage day. The canephoria, as practiſed at Athens, conſiſted in this; that the maid, conducted by her father and mother, went to the temple of Minerva; carrying with her a baſket full of preſents, to engage the goddeſs to make the marriage happy: or rather, as the ſcholiaſt of Theocritus has it, the baſket was intended as a kind of honourable amends made to that goddeſs, the protectreſs of virginity, for abandoning her party; or it was a ceremony to appeaſe her wrath.

CANEPHORUS, in *Botany*, (κανηφορος, baſket-bearing, ſo called from the ſhape of its compound flowers.) Juſſ. 208. Willd. 356. Boſc. nouv. dic. Claſs and order, *pentandria monogynia*. Nat. Ord. *rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth common tubular, toothed, incloſing from three to ſix ſeſſile flowers on a chaffy receptacle; perianth partial, five or ſix-cleft. *Cor.* monopetalous, bell-ſhaped, five or ſix-cleft. *Stam.* Filaments none; anthers five or ſix, oblong. *Piſt.* Stigma two-cleft. *Fruit* pea-ſhaped, inferior, two-ſeeded. Juſſ.

Eſſ. Ch. Calyx common tubular, toothed, many-flowered. Perianth five or ſix-cleft. Corolla bell-ſhaped, five or ſix-cleft. Fruit inferior, two-ſeeded. Willd.

Sp. 1. C. *axillaris*, Lam. Ill. Pl. 151. fig. 1. "Leaves roundiſh, egg-ſhaped; flowers ſolitary, axillary." Leaves oppoſite, narrowing into ſhort petioles, entire. 2. C. *capitata*, Lam. Illuſt. Pl. 151. fig. 2. "Leaves lanceolate; flowers terminal, aggregate, involucred." *Leaves* oppoſite, nearly ſeſſile; entire. *Flowers* three or four together; leaflets of the involucre numerous, briſtle-ſhaped. Both ſpecies found by Commerſon in the iſland of Madagaſcar.

CANES, in Egypt and other Eaſtern countries, a poor ſort of buildings for the reception of ſtrangers and travellers. People are accommodated in theſe with a room at a ſmall price, but with no other neceſſaries; ſo that, excepting the room, there are no greater accommodations in theſe houſes than in the deſerts, but that there is a market near.

CANES *Venatici*, in *Aſtronomy*, the *Grey-hounds*, two new conſtellations, firſt eſtabliſhed by Hevelius, between the tail of the Great Bear, and Bootes' arm, above the Coma Berenices. The firſt is called *Aſterion*, being that next the Bear's tail: the other *Chara*. They comprehend 23 ſtars, of which Tycho only obſerved two. In the Britiſh catalogue they are 25.

CANESCENS, in *Entomology*, a ſpecies of *Apis* mentioned by Lepechin in his travels through Siberia. This inſect is hoary, ſnout incurved, horny, projecting from a conic veſicle: abdomen with obſcure blotches. Inhabits near the Caſpian ſea.

Canescens, a ſpecies of Cantharis found in Saxony. The thorax is yellow: ſternum and elytra obſcure cinereous. Schall.

Canescens, in *Ichthyology*, a ſpecies of Chætodon that inhabits South America and India. The tail of this fiſh is bifid: firſt and ſecond ray of the dorſal fin ſpinous, the third very long; mouth bidentated. Gmel. Linn. Syſt. &c. Figured by Seba, v. 3. pl. 25.

Canescens, in *Ornithology*, a ſpecies of Motacilla, that inhabits New Holland, the plumage of which is hoary-brown above, and white beneath; head black; front ſtreaked with white; breaſt and vent lineated with black; ſpot on the wings, and edge of the tail-feathers at the baſe tawny. Called by late writers the Van Diemen's warbler.

CANET, in *Geography*, a town of France, in the department of the Eaſtern Pyrenées; 5 miles E. of Perpignan.—Alſo, a town of France, in the department of Herrault; 10 miles S.E. of Lodeve.

CANETE. See Cagnate.

CANETHUM, in *Ancient Geography*, a mountain of Greece in Bœotia.—Alſo a place of Greece, in the iſland of Eubœa.

CANETO, in *Geography*, a town of the duchy of Mantua, ſeated on the river Oglio; 20 miles W. of Mantua. N. lat. 40° 55′. E. long. 10° 45′.

CANEVAS, *Fr.* an outline for a poet or muſician to colour. The French chiefly uſe the term in writing words to favourite airs in a ballet; which, after being danced to inſtruments, is impreſſed more deeply in the memory of the audience by being ſung. The word ſeems to be uſed with more propriety when applied to a ſlow and pathetic air, left by the compoſer, as a mere ſketch for the finger to grace and embelliſh. See Cantabile.

CANFRANC, in *Geography*, a town of Spain, in Arragon, 3 leagues N. of Jaca.

CANGA, called by the Portugueſe Cangua, and in China *Cha*, in the *Chineſe Police*, a wooden clog or collar borne on the neck, by way of puniſhment for divers offences.

The canga is compoſed of two pieces of wood notched, to receive the criminal's neck, and this frame of wood has alſo two ſmall holes for the hands of the offender. The load lies on his ſhoulders, and is more or leſs heavy according to the quality of his offence. Some cangas weigh 200 pounds; but moſt of them from 50 to 60 pounds. It is a kind of permanent and ambulatory pillory, which the culprit is ſometimes ſentenced to wear for weeks or for months. The duration of this puniſhment for having broken the peace, or diſturbed a family, or for being a notorious gambler, is generally three months. Although he is ſuffered to walk about, or ſtationed for a certain ſpace of time either in ſome public ſquare, or at the gate of a city or a temple, and occaſionally to reſt under this heavy and degrading burden; yet if the offender is thought by the ſubordinate officer of the civil magiſtrate to have reſted too long, he is beaten with a whip made of leather thongs till he riſes. The mandarins condemn to the canga. When the time of his puniſhment is expired, he is again brought before the mandarin, who exhorts him in a friendly manner to amend, frees him from the canga, and diſcharges him after he has received twenty heavy blows.

CANGANI, *promontory of*, in *Ancient Geography*. See Cangani.

CANGAREE, in *Geography*, a river of America, in South Carolina, formed by the union of the Saluda and Tyger; about 5 miles N.W. from Columbia.

CANGE, Charles Du Fresne Du, in *Biography*, an eminent linguiſt and antiquary, was born in 1610, at Amiens, where, after attending the bar for ſome time at Paris, he devoted himſelf to the ſtudy of the learned languages, and of ancient and modern hiſtory. In 1645, he obtained the poſt of treaſurer of France; and continued at Amiens, blending literary avocations with the functions of his office, till a peſtilence, which prevailed in his native city, in 1668, obliged him to remove to Paris, where he enjoyed peculiar advantages for the proſecution of his ſtudies. Here he was held in high eſtimation for his extenſive learning, for the modeſty and diffidence with which he always expreſſed himſelf concerning his own talents and literary performances, and for the condeſcenſion and affability, which eminently diſtinguiſhed his ſocial intercourſe. After having enjoyed, for 50 years, without intermiſſion, a good ſtate of health, he was ſeized, in 1688, with a retention of urine, which, in a few months, terminated his life. Of his learned works, which were numerous, the following are the principal; viz. "Hiſtory of the Empire of Conſtantinople under the French Emperors," Paris, 1657, fol. "Hiſtory of St. Louis, King of France, by the Sieur de Jouville, illuſtrated with new Remarks and hiſtorical Diſſertations, &c." Paris, 1668, fol. "Joannes Cinnamus's Six Books of the Hiſtory of the Affairs of John and Manual Comnenus, Gr. and Lat. with hiſtorical and philoſophical Notes, &c." Paris, 1670, fol. "A Memoir upon the Plan of a new Collection of the Hiſtorians of France," inſerted in Le Long's Bibliotheque Hiſtorique de la France." "Gloſſarium ad Scriptores mediæ et infimæ Latinitatis, &c." Paris, 1678, 3 vols. fol.; Francof. 1681 and 1710, 3 vols. fol.; reprinted in 1733, by the Benedictines of St. Maur, and augmented with 4 new volumes by the abbé Carpentier. To this work Du Cange owes his chief reputation. It is of ſingular uſe to thoſe who ſtudy the writings and records of the middle ages, and abounds with many intereſting and amuſing anecdotes. "Cyrilli, Philoxeni, alterumque Veterum, Gloſſaria, Latino-Græca et Græco-Latina," 1679, fol. "Hiſtoria Byzantina, duplici Commentario illuſtrata, &c." Paris, 1680, fol. containing the genealogies of the emperors of Conſtantinople, and an accurate deſcription of the ſtate of that city under theſe emperors. "Joannis Zonaræ Annales ab Exordio Mundi ad Mortem Alexii Comneni, &c." Paris, 1686, 2 vols. fol. "Gloſſarium ad Scriptores mediæ et infimæ Græcitatis; accedit Appendix ad Gloſſarium mediæ et infimæ Latinitatis, uná cum brevi etymologico linguæ Galliæ ex utroque Gloſſario," Paris, 1688, 2 vols. fol. "Chronicon Paſchale a Mundo condito ad Heraclii Imperatoris annum vigeſimum," Paris, 1689, fol. Whilſt this work was in the preſs, the learned author died; and it was completed and publiſhed by M. Baluze. His MSS., which were numerous, are preſerved in the king's library. Gen. Dict. Nouv. Dict. Hiſtor.

CANGI, Ceangi, or Cangani, in *Ancient Geography*, a people of Britain, concerning whoſe ſituation antiquarians have been much perplexed. Camden diſcovered ſome traces of them in many different and diſtant places, as in Somerſetſhire, Wales, Derbyſhire, and Cheſhire; and others have found as plain veſtiges of them in Devonſhire, Dorſetſhire, Eſſex, Wiltſhire, &c. Mr. Baxter, (Gloſſ. Brit. p. 73, &c.) ſeems to have diſcovered the true cauſe of this perplexity, by obſerving that the Cangi, or Ceangi, were not a diſtinct nation ſeated in one particular place, but ſuch of the youth of many different nations as were employed in paſturage, in feeding the flocks and herds of their reſpective tribes. Almoſt all the ancient natives of Britain had their Ceangi, the keepers of their flocks and herds, who ranged about the country in great numbers, as they were invited by the ſeaſon, and plenty of paſture for their cattle. Hence we find traces of their name in many different parts of Britain; but chiefly in thoſe parts which were beſt adapted to paſturage. Theſe Ceangi of the different Britiſh nations, naturally brave, and rendered ſtill more hardy by their way of life, were conſtantly armed for the protection of their flocks from wild beaſts; and theſe arms they occaſionally employed in the defence of their country and their liberty.

CANGIAGIO, or CAMBIASO, LUCA, called LUCHETTO, in *Biography*, one of the moſt eminent of the Genoeſe painters, was born at Oneglia, near Genoa, in 1527, and, being of a volatile diſpoſition, was laid under reſtraint by his father, who was his teacher in the art of painting. At the age of 17, he was employed in painting the front of a houſe in freſco; but whilſt he was commencing his work, ſome Florentine painters who were actually engaged, conceived him to be a mere grinder of colours, and when he took up his pallet and pencils, they wiſhed to have prevented his proceeding with it, leſt he ſhould ſpoil the work. However, after a few ſtrokes of his pencil, they were convinced of their miſtake, and reſpected his ſingular abilities. In the exerciſe of his art, he was uncommonly expeditious and rapid, and as he worked equally well with both hands, his performances were numerous and ſpeedily executed. Of Cangiagio it is remarked, that he practiſed three different modes of painting at three different periods of his life. His firſt manner was gigantic and unnatural, which he corrected, in conſequence of the remonſtrances of his friend Aleſſi, the celebrated architect, for his beſt ſtyle, in forming which he conſulted nature with attention, and digeſted his thoughts in ſketches, before he began to paint. His third manner was diſtinguiſhed by a more rapid execution, to which he recurred in order to make more ample proviſion for his wife and family. The death of his wife was followed by a violent paſſion for her ſiſter, to whom he committed the care of his children. With a view of obtaining a diſpenſation from pope Gregory XIII., he took a journey to Rome, in 1576, and enforced his requeſt by preſenting two pictures to his holineſs. The pope, however, inſiſted that he ſhould diſmiſs his ſiſter-in-law from his houſe. After this unſucceſsful application, he proſecuted the exerciſe of his profeſſion at or near Genoa, and performed ſome admirable works in the convent of St. Bartholomew of the Armenians. He was afterwards invited by Philip II. to adorn the Eſcurial; and he complied with the invitation, in hopes of intereſting this powerful monarch in favour of his unallowed and diſquieting paſſion. But the king's courtiers deterred him from communicating his requeſt, much as his performances were admired, to a prince ſo *religious*. Theſe repeated diſappointments preyed upon his mind, and brought on a lingering complaint, which terminated in his death, at the Eſcurial, in 1585. "A great facility of hand, ſkill in drawing, eſpecially fore-ſhortened figures, and fertility of invention, were the characteriſtic excellencies of this painter; but he failed in grace, ſelection, and the truth of nature." In the royal collection at Paris there are a "Sleeping Cupid," as large as life, and likewiſe "Judith with her Attendant," which do honour to this maſter. In the Pembroke collection at Wilton, there is a picture, repreſenting Chriſt bearing his croſs, which is aſcribed to Cangiagio. D'Argenville. Pilkington.

CANGIAMILA, FRANCIS, EMANUEL, canon of the church at Palermo, and inquiſitor of the iſland of Sicily, where he died, in 1763, publiſhed "Embryologia ſacra, ſive de officio ſacerdotum, medicorum, et aliorum circa æternam parvulorum in utero exiſtentium ſalutem," Palermo, 1761, fol. By the canons of the church of Rome, it has been decreed, that children may be efficaciouſly baptized before they are born, if the water can be made to touch any part of their bodies, or the membranes in which they are involved; and ſurgeons are cautioned to ſee this ceremony performed, whenever, from the difficulty of the labour, the life of the child ſhall appear to be in danger. On the other hand, they are admoniſhed, that to open the head of a child before it is certainly known to be dead, with a view of preſerving the life of the mother, is to commit murder, and conſequently not to be allowed. An abridged edition of this work was publiſhed by the abbe Dinouart, in 1761, and 1766, 12mo. Haller Bib. Anat. Eloy. Dict. Hiſt.

CANGIANO, in *Geography*, a town of Naples in the province of Principato Citra; 27 miles N. of Policaſtro.

CANGOXIMA, CANGOXUMA, or COGOXIMA, is a ſea port on the moſt ſouthern verge of the iſle of Japan. It was the firſt at which the Portugueſe landed, and they afterwards choſe to make it the centre of their commerce, on account of its advantageous ſituation and commodious harbour. The entrance into it is, indeed, dangerous by reaſon of a number of rocks, that lie at ſome diſtance from it; on one of which is ſeated a ſtrong caſtle, ſaid to have been built by Ongoſchio, the grandfather of the emperor Gongon, or Gonjin, with a view of ſecuring the city, which is the key of the kingdom of Saxuma, and of the whole iſland. At the entrance of the haven was conſtructed a ſquare lighthouſe, ſituate on a very high rock, which is viſible at ſea at the diſtance of above 20 miles; and at the foot of the rock is a convenient road for ſhipping. The quay is guarded by a ſtone dyke, which runs into the ſea, and has a ſtone rampart breaſt-high, covered with copper. In each of 2 large wings built at one end of it are ſtationed 500 men, who keep watch night and day, to check the kings of Saxuma, who often revolted in order to avoid paying tribute to the emperors. The town is watered by a river which deſcends from the mountains into a canal formed for receiving it, and from thence it falls with great rapidity into the ſea. On the ſouth ſide of the river is a cuſtom-houſe for receiving duty, beſides other large and ſumptuous magazines belonging to the emperor.

CANHAR, a river of Hindooſtan, which runs into the Soane, 5 miles S.W. of Bidjigur.

CANI, two ſmall flat iſlands of Africa, in the Mediterranean, near the coaſt of Tunis, ſituate about 4 leagues to the north-north-weſt of the cape Pil-loe, and very nearly in the middle way to cape Blanco. Theſe iſlands ſeem to occupy the ſituation aſſigned by Ptolemy to his Inſula Dracontia. N. lat. 37° 45′. E. long. 10° 30′.

CANI, *Grotto del.* See GROTTO *del Cani.*

CANJA, in *Nautical Language*, a veſſel employed on the Nile, and repreſented by Mr. Bruce as commodious, ſafe, and expeditious in ſailing. That which he deſcribes (Travels to Africa, Vol. I. p. 43.) was about 100 feet from ſtem to ſtern, with two maſts, main and foremaſt, and two monſtrous latine ſails, the main-ſail-yard being about 200 feet in length; about 30 feet in the beam, and about 90 feet in keel. The keel is not ſtraight, but a portion of a parabola whoſe curve is almoſt inſenſible to the eye, but having this advantageous effect in ſailing, that as the bed of the Nile, when the water becomes low, is full of ſand-banks under water, the keel under the ſtem, where the curve is greateſt, firſt ſtrikes upon theſe banks and is faſt, but the reſt of the veſſel is afloat; ſo that by the help of oars and aid of the ſtream, furling the ſails, you eaſily get off; whereas, if the keel were ſtraight, and the veſſel advanced with the preſſure of its immenſe main-ſail, it muſt remain immoveable upon the bank, and be wrecked. When this veſſel is proceeding up the ſtream, before the wind, the yard and ſail are never lowered. The ſailors climb and furl it as it ſtands. When they ſhift the ſail, they do it with a thick ſtick like a quarter-ſtaff, which they call a "noboot," put between the laſhing of the yard and the ſail; they then twiſt this ſtick round till the ſail and yard turn over to the ſide required. When the veſſel returns, they take out the maſt, lay down the yards, and put by their ſails, ſo that the boat deſcends like a wreck broadſide forwards; otherwiſe being ſo heavy a-loft, were ſhe to touch with her ſtem going down the ſtream, ſhe would not fail to carry away her maſts, and perhaps be ſtaved to pieces. The cabin of this veſſel has a very decent and agreeable dining-room, about 20 feet ſquare, with windows that have cloſe and latticed ſhutters, ſo that they may be opened at pleaſure in the day-time, and admit the freſh air; but they ſhould be carefully kept ſhut at night. See *Plate of Ship*.

CANIADERAGO, in *Geography*, a lake of North America, in the county of Otſego or Oſwego, and ſtate of New York. It is as large as the Oſwego lake, and 6 miles weſt of it. From this lake iſſues a ſtream, called Oaks creek, which falls into Suſquehannah river, about 5 miles below Oſwego. The beſt cheeſe in the ſtate is made on this creek. N. lat. 42° 43′. W. long. 75°.

CANICODEO, *creek*, a ſouth-weſt head-water of Tioga river in New York, which interlocks with the head-waters of Geneſſee river, and joins Coneſteo creek, 26 miles W.N.W. from the Painted Poſt.

CANICULA, in *Ichthyology*, a ſort of SQUALUS, or Shark, that ſwarms in all the European ſeas, and preys on fiſh. The Engliſh fiſhermen are well acquainted with this voracious creature by the name of the Spotted Dog-fiſh, the head, back, ſides, and fins being marked with large diſtinct black ſpots on a browniſh ground, with only the belly and lower part of the ſides white. This fiſh ſeldom exceeds the length of four, or at moſt, five feet. The ſkin, when dried, is uſeful for various purpoſes. The ſpecies is known by having the noſtrils ſurrounded by a lobe and vermiform appendage, and the ventral fins diſtinct; a character that muſt be attentively conſidered, in order to determine the *Squalus Canicula* from its very analogous ſpecies *Squalus Catulus*, the latter differing principally in being of a ſmaller ſize, and having the ventral fins united. Vide Donov. Brit. Fiſhes.

Obſ. This is the Linnæan Squalus Canicula, Squalus conducta of Oſbeck; Catulus major of Jonſton, and Rouſſette of moſt French writers.

CANICULA, in *Aſtronomy*, is a name given to one of the ſtars of the conſtellation CANIS *major*; called alſo ſimply the *Dog-ſtar*; by the Greeks, Σειριος, *Sirius*.

Pliny and Galen alſo give the appellation Procyon to the *Canicula*; though, in propriety, PROCYON is the name of another ſtar, in the Leſſer Dog.

*Canicula* is the tenth in order in the Britannic Catalogue; in Tycho's and Ptolemy's it is the ſecond. It is ſituate in the mouth of the conſtellation, and is of the firſt magnitude; being the largeſt, and brighteſt, of all the ſtars in the heavens.

From the heliacal riſing of this ſtar, that is, its emerſion from the ſun's rays, which now happens about the 11th day of Auguſt, the ancients reckoned their *dies caniculares*, or dog-days.

The Egyptians and Ethiopians began their year at the riſing of *Canicula*; reckoning to its riſe again the next year, which is called the *Annus Canarius*.

CANICULAR *days*, properly denote a certain number of days, preceding and enſuing the heliacal riſing of Canicula, or the Dog-ſtar, in the morning; to which the ancients aſcribed an extraordinary influence.

This opinion, equally erroneous and ſuperſtitious, ſeems to have originated with the Egyptians, who, obſerving the riſing of the Dog-ſtar, which anciently took place in Egypt about the time of the ſun's arrival at the ſummer tropic, when the Nile began to riſe, upon the overflow of which the fertility of their country depended, were induced to pay divine honours to this ſtar. They imagined that it not only indicated the time of the Nile beginning to riſe, but that it was the efficient cauſe of its overflowing, or of the fertility connected with this circumſtance. From the colour of the ſtar at its firſt appearance, they formed prognoſtics what kind of ſeaſons they were to expect; ſo that if it were of a golden colour, they thought it preſaged a fruitful year; but if it appeared pale and dim, they regarded it as a bad omen, that portended a ſcarcity. They fancied alſo, that the Dog-ſtar riſing with the ſun and joining his influence to the fire of that luminary, was the cauſe of the extraordinary heat which uſually falls out in that ſeaſon; and accordingly they gave the name of the *dog-days* to about ſix or eight weeks of the hotteſt part of ſummer. The Greeks, in imitation of the Egyptians, their maſters in idolatry and ſuperſtition, as well as ſcience, held the ſame opinion, that the dog-ſtar was the cauſe of that ſultry heat ſo often pernicious to the health and life of man. Homer, (Iliad l. xxii. v. 30.) comparing the ſhining of the armour of Achilles, whoſe fury was ſo fatal to the Trojans, to the pernicious blaze of the Dog-ſtar riſing at the end of ſummer, calls it an ill omen, "portending heat intenſe to wretched mortals;" or as the ſenſe of the paſſage is well expreſſed by Pope:—

> ————————"his burning breath
> "Taints the red air with fevers, plagues, and death."

When the father of the poets had expreſſed himſelf in this manner, it is no wonder that others ſhould ſpeak of the rage of the dog-ſtar, as ſome of them do of the fury of the lion, (Hor. l. iii. Od. 9. Virg. Æn. l. x. v. 270.) becauſe a ſtar of the firſt magnitude, called the Lion's heart, riſing in the time of the dog-days, was alſo thought to contribute towards the great heat of that ſeaſon.

Some authors tell us, from Hippocrates and Pliny, that on the day the Canicula firſt riſes in the morning, the ſea boils, wine turns ſour, dogs begin to grow mad, the bile increaſes and irritates, and all animals grow languid; and that the diſeaſes ordinarily occaſioned in men by it are burning fevers, dyſenteries, and phrenſies. Although Hippocrates had a ſentence or aphoriſm that ſeems to forbid the uſe of purging medicines in the dog-days, we muſt not conclude from hence that great phyſician and philoſopher to have thought the influence of the Dog-ſtar conſiderable. It is probable, that he only meant to point out the hot time of the year, commonly marked by the riſing of the Dog-ſtar. The Romans ſacrificed a brown dog every year to Canicula at its riſing, to appeaſe its rage. They ſuppoſed Canicula to be the occaſion of the ſultry weather, uſually felt in the dog-days.

As to the dog-days attended to by ſome with ſo much ſuperſtitious regard, it is pleaſant to obſerve what variety of opinions have prevailed both among the ancients and moderns about the beginning and the end of them. This variety is, in ſome inſtances, owing to the ignorance of the writers, who did not know or conſider that the Dog-ſtar varies in the time of its riſing in any one year as the latitude varies, and that it is always later and later every year in all latitudes; ſo that in time, this ſtar, by the ſame rule, may chance to be charged with bringing froſt and ſnow, when he riſes in winter. In an ancient calendar preſerved by Bede, the beginning of the dog-days was placed on the 14th of July. In one prefixed to the common prayer, printed in the time of queen Elizabeth, they are ſaid to begin on the 6th of July, and to end on the 5th of September; and this was continued from that time till the reſtoration, when that book was reviſed, and the dog-days omitted. From that time to the correction of the Britiſh calendar, our almanacs had the beginning of the dog-days on the 19th of July, and the end on the 28th of Auguſt: but ſince that correction, the times of the beginning and end have been altered; and the former was placed at the 30th of July, and the latter at the 7th of September. The dog-days have been commonly reckoned for about 40 days, viz. 20 days before, and 20 days after the heliacal riſing; and almanac-makers have uſually ſet down the dog-days in their almanacs to the changing time of the ſtar's riſing; and thus they had at length fallen conſiderably after the hotteſt ſeaſon of the year; till of late, a very proper alteration has been introduced into the almanacs, and they have been made to commence with the 3d of July, and to terminate with the 11th of Auguſt. The propriety of this alteration will be evident, if we conſider, that the ancients meant to expreſs by the dog-days, the hotteſt time of the year, which is commonly during the month of July, about which month, the Dog-ſtar roſe heliacally in the time of the moſt ancient aſtronomers, whoſe obſervations have been tranſmitted to us: but the preceſſion of the equinoxes has transferred this heliacal riſing to a much later and cooler part of the year; and becauſe Heſiod tells us that the hot time of the year ends on the 50th day after the ſummer ſolſtice, which brings us to about Auguſt 10, or 11, the above-mentioned alteration ſeems to be not only neceſſary, but very proper.

CANICULAR *year*, denotes the Egyptian natural year, which was computed from one heliacal riſing of Canicula to the next. This is alſo called annus canarius, and annus cynicus; by the Egyptians themſelves the Sothic year, from Soth, a denomination given by them to Sirius. Some alſo call it the heliacal year.

The canicular year conſiſted ordinarily of 365 days, and every fourth year of 366 days, by which it was accommodated to the civil year. The reaſon of their choice of Canicula before the other ſtars, to compute their time by, was not only the ſuperior brightneſs of that ſtar, but becauſe its heliacal riſing was in Egypt a time of ſingular note, as falling on the greateſt augmentation of the Nile, the reputed father of Egypt. Epheſtion adds, that from the aſpect of Canicula, its habit and colour, the Egyptians drew prognoſtics concerning the riſe of the Nile; and, according to Florus, predicted the future ſtate of the year. So that the firſt riſing of this ſtar was yearly obſerved with great attention. Bainbrigge, Canicul. cap. 4. p. 26.

As the Egyptian year of 365 days was about ſix hours ſhorter than the true ſolar year, the heliacal riſing of Sirius gradually advanced, at the rate of nearly one day in the interval of four years; ſo that in 1461 years, it completed a revolution, by riſing on every ſucceeding day of the year, and returning to the point originally fixed for the beginning of the firſt month, called *Thoth*, or *Soth*. This period, equal to 1460 Julian years, was termed the great Egyptian year, or "Canicular cycle." Cenſorinus (De Dei Nat. c. 18.) informs us, that in the conſulate of Antoninus Pius, and Brutius Præſens, A.D. 138, the canicular year was renewed. If we reckon backwards 1460 Julian years, we come to the year B. C. 1322, when the ſun was in 14° of Cancer, that is, 14 or 15 days after the ſummer ſolſtice, which happened on July the 5th. Again, in the beginning of the Nabonaſſarean æra, i. e. B. C. 747, the Thoth, or firſt day of the Egyptian year, had receded to the 26th of February, from July the 20th, when Sirius had been obſerved to riſe heliacally in Egypt. This interval of 144 days, multiplied by four, gives 576 years. The canicular year muſt, conſequently, have begun 576 years earlier than the æra of Nabonaſſar, viz. in the year B. C. 1322, or 1323, which nearly correſponds with the former date. In this matter, great accuracy cannot be expected, as the obſervation of the heliacal riſing or ſetting of a ſtar depends upon the ſtate of the atmoſphere, the difference of latitude, the ſituation of the obſerver, and other circumſtances. Bailly (Hiſt. de l'Aſtron. l. vi. c. 8.) fixes the date of the eſtabliſhment of this period in the year B. C. 2782, on the authority of a paſſage ſaid to have been extracted out of Manetho's hiſtory, which intimates, that the ſhepherds invaded Egypt in the 700th year of the Sothic cycle; and in a vague tradition, that it commenced when Sirius roſe heliacally at the ſummer ſolſtice. But the grounds of this opinion are ſuch as to entitle it to no great regard.

CANICULATUS, in *Conchology*, a ſpecies of MYTILUS that inhabits New Zealand. The ſhell is ſmoothiſh, and brown without, the interior ſurface tinged with various colours, and the ſocket of the hinge grooved. Martyn. &c.

CANICULUM, or CANICULUS, in the *Byzantine Antiquities*, a golden ſtandiſh, or ink veſſel, decorated with precious ſtones, wherein was kept the ſacred *encauſtum*, or red ink, wherewith the emperors ſigned their decrees, letters, &c. The word is by ſome derived from *canis* or *caniculus*; alluding to the figure of a dog, which it repreſented; or rather becauſe it was ſupported by the figures of dogs. By Salmaſius it is derived from κανιον, an inkhorn. The caniculum was under the care of a particular officer of ſtate, hence called *caniclinus* or *canicleus*, who was in great requeſt. Du-Cange will have the *caniclinus* to have been the ſame with the LOGOTHETA.

CANIGOU, in *Geography*, an eminence of the Pyrenées, about 1440 French toiſes.

CANINA, a town of European Turkey, in Albania; ſituate in a diſtrict of the ſame name on the ſea-coaſt, near the gulf of Venice. N. lat. 40° 28′. E. long. 19° 50′.

CANINA, in *Zoology*, a ſpecies of ASCIDIA that inhabits the Atlantic and northern ſeas. It is of an elongated ſhape, round and flaccid, with a red pouch. Müll. Zool. Dan. Obſ. This is the *ſac-animal* of Dicquemar, and *Mentula marina* of Redi. Bohadſch calls it *Tethyum faſciculatum*.

CANINA, a ſpecies of BOA, deſcribed by Linnæus as having 203 abdominal plates, and 77 caudal ſcales. This beautiful ſnake is an inhabitant of South America; where it frequently rolls itſelf round trees, from whence it can the more readily perceive and dart upon its prey. The uſual length of this ſnake is about four feet, and its thickneſs moderate in proportion. Its head is large, and bears ſuch a ſtriking reſemblance to that of a dog that Linnæus gave it the ſpecific name of canina, in alluſion to that circumſtance. The colour of the whole animal on the upper parts is of a fine ſaxon-green, with ſeveral ſhort, undulating, tranſverſe white bars down the back, the edges of which are of a deeper green than the ground-colour of the body: the abdomen is white.

Boddaert ſpeaks of a ſpecimen of this boa in which the abdominal plates amounted to 208 inſtead of 203, at the ſame time that the ſub-caudal ſcales were exactly the ſame in number as Linnæus deſcribes them. That examined by Gronovius differed in both particulars from the Linnæan ſpecimen, having 205 abdominal plates and 79 ſub-caudal ſcales.

Laurenti deſcribes this ſpecies under the title of boa thalaſſina:

laſſina: Seba by thoſe of Serpens Bojobi braſilienſis, Tetrauchoatl Tleola, and Luſitanis Cobre verde.

There is another kind of ſnake very cloſely allied to the above ſpecies, that inhabits the Eaſt Indies, and is ſuppoſed by Gmelin to be a variety only of the ſame ſnake. Laurenti calls it Boa aurantiaca, and Seba Serpens Bojobi ceylonica: the ground colour is of a fine orange: the dorſal bands pale yellow, edged with red, and the abdomen pale yellow.

CANINANA, the name of a ſpecies of ſerpent found in America, and eſteemed one of the leſs poiſonous kinds. It grows to about two feet long, and is green on the back, and yellow on the belly. It feeds on eggs and ſmall birds; the natives cut off its head and tail, and eat the body as a delicate diſh. Ray.

CANINE, in a general ſenſe ſomething that relates to dogs.

Canine *appetite, appetentia et fames canina.* See Bulimia.

Canine *laughter, riſus caninus*, that wherein the lips are drawn far back, and the mouth much extended.

Canine *ligament*, is that whereby the prepuce of the human penis is faſtened to the glans, otherwiſe called the frænum.

Canine *madneſs, rabies canina.* See Hydrophobia.

Canine *ſulphur*, a ſort of native ſulphur, diſcovered near Reggio, intermixed with earthy or ſtony matters; thus called by reaſon that dogs are ſo fond of it, as to dig it out of the earth.

Canine *teeth; canini dentes.* See Teeth.

Caniné, in *Geography*, a town of Africa, in the kingdom of Angola; ſeated on the river Lucala, S. lat. 8° 56′. E. long. 17° 28′.

Canini, Angelo, in *Biography*, a learned grammarian of the ſixteenth century, was born in a ſmall city in Tuſcany, called Anglara, or Anghiari; and employed himſelf for ſeveral years in teaching the Oriental languages in Venice, Padua, Bologna, Rome, Spain, and France. At Paris he had for his ſcholar, Andrew Dudith, an Hungarian, afterwards celebrated for his learning and embaſſies. At length he entered into the ſervice of William du Prat, biſhop of Clermont; and he died in Auvergne in 1557. His "Inſtitutiones Linguæ Aſſyriacæ atque Thalmudicæ, una cum Æthiopicæ atque Arabicæ Collatione, &c." Paris, 1554, 4to. are much eſteemed. His "Greek Grammar," or "Helleniſmi." Paris, 1555, 4to. has been highly commended; and by Tanaquil Faber of Saumur, who prefers Caninius before all other grammarians, it is denominated "The Treaſure of Helleniſm." "A Latin Tranſlation of Simplicius's Commentary upon Epictetus's Manual," printed at Venice in 1546, fol. is attributed to this author. Gen. Dict.

Canini, in *Ancient Geography*, a country of Rhætia, ſuppoſed to be that of the Griſons.

Caninus *muſculus*, in *Anatomy*, the ſame as *elevator labii ſuperioris*, which ſee.

CANIOPOLIS, in *Ancient Geography*, the name of an ancient epiſcopal town of Thrace, mentioned in the acts of the council of Sardica, held in 347.

CANIPSA, or Capsina, a town of Arabia Felix, ſeated on the Perſian gulf; W. of the mouth of the river Lar. Ptolemy.

CANIS, in *Zoology*, a ſpecies of Ascaris, that infeſts the inteſtines of the common dog. This kind is diſtinguiſhed by having the tail pointed, the head flat, and furniſhed on each ſide with a wing-like membrane, and the ſpermatic veſſels curled. Wern. Verm. Inteſt. &c.

Canis, a genus of the Mammalia Feræ, diſtinguiſhed by the following character: fore teeth, upper ſix; lateral ones longer, diſtant; intermediate ones lobate; lower ſix, lateral ones lobate: tuſks ſolitary and incurvated; grinders ſix, ſeven, or more than in others.

This genus comprehends the common dog, *familiaris*, and its varieties, with the ſpecies Lupus, Mexicanus, Thous, Hyæna, Crocuta, aureus, Meſomelas, Lycaon, Vulpes, Alopex, Corſac, Karagan, cinereo-argenteus, virginianus, Lagopus, and Cerdo, which ſee reſpectively.

Canis *Major, the Great Dog*, in *Aſtronomy*, a conſtellation of the ſouthern hemiſphere, below Orion's feet, though ſomewhat to the weſtward of him; whoſe ſtars Ptolemy makes 29; Tycho only obſerved 13; Hevelius 51; in the Britannic Catalogue they are 31.

It is unneceſſary to advert to the fables of the Greeks concerning the elevation of the dog to the heavens, as the origin of this conſtellation, as well as of its other name Sirius, is more probably to be found in the ſuperſtition of the Egyptians; who, as we have already obſerved, (See Canicular *days*), carefully watched the riſing of this ſtar, and judging by it of the ſwelling of the Nile, called the ſtar the centinel and watch of the year. Hence, according to their mode of hieroglyphic writing, they repreſented it under the figure of a dog; they alſo called this ſtar Iſis, the name given to their great goddeſs, and Thoth, the name of their god Mercury, whom for his ſagacity in the invention of letters, arts, and ſciences, they ſometimes painted in the form of a dog, or of a man with a dog's head, and worſhipped him under the name of "Anubis," which ſee. They called the ſame ſtar "Sothis," or Siothi," which, in the Egyptian language, according to Kircher, ſignifies holy. Sidor and Siris are alſo other names for the Nile, from whence Voſſius derives Sirius, the Greek name of this ſtar, which was imagined to have ſuch dominion over that river; and alſo Oſiris, the name of one of their principal deities.

Canis *Minor, the Little Dog*, a conſtellation of the northern hemiſphere; called alſo by the Greeks, *Procyon*, and by the Latins *Antecanis* and *Canicula*. This, as well as the former, is one of the old 48 conſtellations. According to the fables of the Greeks, it is one of Orion's hounds: but the Egyptians were probably the inventors of this conſtellation, as well as Canis Major; and they might have given it this figure to expreſs a little dog, or watchful creature, preceding and conducting, as it were, the larger, or riſing before it; hence the Latins have denominated it *Antecanis*, which ſee. The ſtars in the conſtellation Canis Minor are in Ptolemy's Catalogue 2; in Tycho's 5; in Hevelius's 13. In the Britiſh Catalogue they are 14, of which the principal is Procyon.

Canis *flumen*, or Cynos *flumen*, the river of the dog, in *Ancient Geography*, a river of Arabia Felix, which diſcharged itſelf into the Perſian gulf: probably the ſame with the *Lar* of Ptolemy.

Canis *Carcharius*, in *Ichthyology*. See Squalus Carcharis.

Canis *Galeus*. See Squalus Galeus.

Canis *Volans*, in *Zoology*, a name indiſcriminately given by old writers to the vampire and ternate bat, Veſpertilio Spectrum and Vampyris. Canis volans was alſo called veſpertilio cauda nulla, both the above being of the tailleſs kind of bats. Canis volans ternatanus orientalis of Seba is the Great Bat; Canis volans maxima aurita ex Nova Hiſpana of the ſame writer is the Vampire of Buffon.

CANISBAY, in *Geography*, a ſmall fiſhing town of Scotland, in the county of Caithneſs, and moſt northern part of Scotland; 11 miles N. of Wick.

CANISCHA, a town of Hungary, taken by the Turks in 1600 and retained by them till the year 1690, when it was captured by the imperial troops after a blockade of 2 years, and ceded to the emperor by the peace of Carlowitz; 96 miles S. of Vienna.

CANISIUS, Henry, in *Biography*, a native of Nimeguen, who became profeſſor of canon law at Ingolſtadt, and who was no leſs diſtinguiſhed for his piety and modeſty than for his erudition. He died in 1610. Among his works in law and antiquities, which are highly eſteemed, we may mention his "Summa Juris Canonici;" "Commentarium in Regulas Juris;" "Prælectiones academicæ de Decimis primitiis, &c." and his "Antiquæ Lectiones," 6 vols. 4to. containing a collection of curious pieces relating to the hiſtory and chronology of the middle ages, printed by J. Baſnage, in 7 tomes, 4 vols. fol. Amſterd. 1725; with learned prefaces and remarks by the editor; and notes, with various readings, by Capperonier. Nouv. Dict. Hiſtor.

CANISOLA, in *Geography*, a town of the iſland of Cherſo, in the Adriatic; 22 miles N. of Cherſo.

CANISTER, *Great*, a ſmall iſland in the bay of Bengal, near the coaſt of Siam. N. lat. 12° 58′. E. long. 97° 40′.—*Little Caniſter*, another ſmall iſland in the ſame bay and near the ſame coaſt; 2 leagues S. from the former.—*Weſt Caniſter*, a ſmall iſland in the ſame bay, near the ſame coaſt. N. lat. 12° 37′. E. long. 97° 16′.

CANISY, a town of France, in the department of the Channel, and chief place of a canton, in the diſtrict of St. Lo, 4 miles S.W. of St. Lo. The place contains 838, and the canton 9060 inhabitants; the territory includes 90 kiliometres and 12 communes.

CANITZ, *baron of*, in *Biography*, a German poet and ſtateſman, was of an ancient and illuſtrious family in Brandenburg, and born at Berlin in 1654. After having completed his early ſtudies, he travelled to France, Italy, Holland, and England; and upon his return, he was charged with important negociations by Frederic II. He was alſo employed by Frederic III. Although he was more extenſively known as a politician than a poet, his poems have been much admired by his countrymen, and they were publiſhed for the tenth time in 1750, 8vo. Moſt of them were of the moral elegiac kind, expreſſive either of the tendereſt ſentiments of conjugal affection, or of ſuch reflections as naturally occurred to a contemplative and virtuous mind on the various events of life. Horace is ſaid to have been his model, and his compoſitions are written in a pure and delicate ſtyle. He was eminently learned and ingenious, virtuous and benevolent. Having attained the office of privy counſellor of ſtate, he employed the influence acquired by his diſtinguiſhed character and high ſtation in giving encouragement to literature and the fine arts. The diſeaſe which terminated his life was tedious and lingering, and he obſerved the ſlow but certain approaches of his laſt enemy with the calmneſs and fortitude that became the chriſtian philoſopher. When his phyſicians had pronounced his caſe to be hopeleſs, he ordered a ſkull to be brought to him, and dictated ſome poetical meditations on this object in connection with his own circumſtances, which are juſtly deemed the moſt beautiful of his productions. He retained his cheerfulneſs to the laſt; and juſt before his death, deſired to be led to the window, which he opened: when, having gazed ſome minutes at the riſing ſun, he exclaimed, "O! if the view of a part of the creation can be thus beautiful and reviving, how infinitely delightful muſt be that of the Creator!" He ſpoke, and died, in 1699, at the age of 45. Bildniſſe, &c. or Portraits of celebrated German literati, &c. Berne, 1793.

CANKER, in *Gardening*, a vegetable diſeaſe common in fruit and other trees, produced by a ſort of ulceration in the bark ariſing from bruiſes, the old or dead wood remaining on the trees, and various other cauſes. It is obſerved by the author of the Philoſophy of Gardening, that this diſeaſe may be termed *gangrena vegetabilis*, and that it is a phagedenic ulcer of the bark, which is very deſtructive to apple-trees and pear-trees, as it ſpreads round the trunk or branches, and deſtroys them. Mr. Knight has obſerved "it to be moſt frequent and fatal to thoſe trees the fruit of which has been long in faſhion, having been perpetually propagated for a century or two by ingrafting; which he believes to be a continuation of the old tree, though nouriſhed by a new ſtock; and that the canker is thus a diſeaſe of old age like the mortification in the limbs of elderly people, and ariſes from the irritability of a part of the ſyſtem."

But it ſeems more probable in the opinion of the firſt writer, that "it is an hereditary diſeaſe, as the buds of trees being a lateral progeny, and more exactly reſembling their parents, muſt be more liable to the diſeaſes gradually acquired, or increaſed, by the influence of ſoil or climate, and have not the probability of improvement which attends the progeny of ſexual generation. It is nevertheleſs frequently produced on trees by external violence, as a ſtroke with a ſpade given by a careleſs labourer who is digging near them; but this probably may more eaſily affect the old grafts above-mentioned. When a deſtruction of the bark is thus produced by external violence, it may poſſibly, he ſuppoſes, be cured by the application of a piece of living bark from a leſs valuable tree bound upon it."

It is likewiſe recommended, that "the edges of theſe gangrenous ulcers of the bark ſhould be nicely pared off with a knife, ſo as to admit the air and to prevent the depredations of inſects, and the lodgment of moiſture, which might promote the putrefaction of the ſtagnant juices, and ſpread the gangrene. This ſhould be ſo managed as only to cut away the dead lips of the wound, but not ſo as to injure the living bark. Some thick white paint may then be ſmeared on the naked alburnum, or ſap wood, on a dry day, which may prevent inſects from inſerting their eggs into it, and producing maggots, which erode and deſtroy the wood, and may alſo prevent the dews and rain from rotting it. The paint ſhould, nevertheleſs, be ſo ſpread as not to touch the edges of the wound, as it might injure their growth by its poiſonous quality. A quarter of an ounce of ſublimate of mercury, "*hydrargyrus muriatus*" rubbed with about a pound of white lead-paint renders it more noxious to inſects."

Mr. Forſyth thinks it a miſtake that it always depends upon the nature of the ground, as ſour clays or ſhingly gravels. He contends that it invariably proceeds from the branches to the roots of the trees, and never in the contrary direction.

In the cure of this diſeaſe, when extenſive, he adviſes the careful paring off with a draw-knife or other convenient inſtrument of "all the diſeaſed parts of the bark." And that as the inner white bark is frequently infected, this muſt alſo be cut away, till no appearance of infection remains. The infection in the inner bark appears like dots made with a pen, all of which muſt be cut clean out; for if any part of the canker be left, it will infect the new wood and bark. Wherever you ſee gum oozing out, you may reſt aſſured that the canker is not quite eradicated; which, if ſuffered to remain, will ſpread till the whole tree becomes a maſs of gum and canker, and will be killed in a very ſhort time. When the trunk is become hollow, cut the looſe rotten part clean out, till you come to the ſound wood, taking care to round the edges of the hollow part; then apply the compoſition in a liquid ſtate, laying it on with a painter's bruſh wherever the cankered bark has been pared off or the dead wood cut out, till theſe places are entirely covered with it; when that is done, ſhake ſome of the powder of wood aſhes and burnt bones over the compoſition, and pat it gently down with your hand." See Composition.

He contends, "that if the foregoing directions be carefully followed, the canker will be completely eradicated, and the hollow trunk in time be filled up with ſound wood. When the ſtem is much decayed, he thinks it will be abſolutely neceſſary to open the ground, examine the roots, and cut off all the rotten parts. When you have cut out all the rotten and decayed parts below ground, and ſcraped the hollow clean, make up a maſs of the compoſition, mixed with ſome clay, like what is uſed for grafting; then fill the hollow part with it to within two inches of the ſurface of the ground, treading it in with your foot, or preſſing it in with the hand as cloſe as you poſſibly can, to prevent the wet from penetrating to the roots, and leave the ſurface of the compoſition ſloping from the tree towards the outſide of the border to throw the wet off, which will prevent the freſh part of the root from rotting; then cover the root over with mould level with the reſt of the border;" and, "when you have examined all the old wounds, where large limbs have been cut off, you ſhould next examine the old bark; and if you ſhould find the outſide of it wrinkled and cracked, pare it off, as it is always, when in that ſtate, very much hurt by the canker. This ſhould be done with the draw-knife, or other ſharp inſtrument; then apply the compoſition as before directed, which will bring on a fine ſmooth bark under it. In the ſucceeding winter or ſpring, you will ſee all the plaſter with the old part of the bark that was left in the hollow parts of the tree, or where old branches had been amputated, peeling off and ſhewing the ſmooth bark underneath. You ſhould then ſcrape off, with a wooden or bone knife, what old bark remains in the hollows where the draw-knife could not reach, without cutting too much away. When that is done, mix up ſome freſh cow-dung with ſoap-ſuds and urine, making it very thin, and give the tree a coat of this mixture all over where the bark has been ſcraped off; the cow-dung will adhere to it, and heal the parts where you were obliged to ſcrape to the inner bark. This waſh will, he ſays, remain till the freſh bark comes on; then it will be diſcharged of itſelf, during the ſummer, or the next ſpring, leaving a new freſh bark where the old and cankery was taken off. Next ſpring, if any of the old bark remains, you may repeat the ſame operation, which will cauſe all the remaining old bark to ſlough off like a ſcab from a wound of a human body. By theſe means, he contends, that you will keep your trees in a fine flouriſhing healthy ſtate, and, in general, prevent them from becoming bark-bound. If any of them, notwithſtanding, ſhould be bark-bound, you muſt ſcarify them, by taking a ſharp knife, and running the point of it ſtraight down the middle of the ſtem from top to bottom, taking care to run your knife through the outer bark only; then, with a bruſh, or your finger, rub in ſome of the compoſition, to prevent the inciſion from bringing on the canker."

This operation will cauſe the tree to expand the bark and become very flouriſhing.

And it is adviſed to remember to cut off all the ends of the ſmall ſhoots where the canker had injured them laſt year.

Cut off alſo the old fruit ſtalks, and all the ſmall dead ſtubs, which, if left, will never fail to bring on the canker.

The rough, or cankery bark, or that ſide of trees which is next the wall, ſhould be ſcraped or pared off with a tool made in the form of a ſickle. "It is much," he ſays, "to be regretted, that fruit-trees in general, throughout this kingdom, are in a mutilated, unfruitful ſtate. After gentlemen have purchaſed the young trees from nurſeries, and planted them in their orchards and gardens, they think, ſays he, that every thing neceſſary is done; when, in fact, the greater part of the work is yet to come. In packing a carriage, the ſtems and branches are very frequently bruiſed; in that caſe, the injured parts of the bark and wood muſt be carefully cut out, and the compoſition immediately applied: this may be done when you head the trees, which operation ſhould be performed in April, May, or even June, when the buds begin to ſhoot; but by no means cut off any of the ſhoots, except thoſe that are broken or bruiſed very much. When this is neglected, the canker will follow to the great injury, if not death, of the trees.

"How common, continues he, is it to ſee, in all parts of the country, great numbers of trees ſo affected with this diſeaſe, as not to produce fruit enough in twelve or fourteen years to pay half the expence attending them; whereas, if they were to be managed according to the foregoing directions, they would more than pay all the expence in three years. It is common, when young trees do not thrive, either to blame the nurſery-men for ſending bad or diſeaſed trees, or to attribute their unthriving ſtate to the nature of the ſoil; whereas the fact is, that this frequently ariſes from the inattention or miſmanagement of the perſon who plants and ſuperintends them.

"If the injured and diſeaſed parts be not cut out at an early period, the trees will not thrive, but will become cankery and ſtunted, and cannot be recovered afterwards without a great deal of labour and trouble; whereas, if the directions given for heading trees the firſt year, and cutting out the diſeaſed parts, be attended to, the trees will flouriſh and bear large crops of fine and well-flavoured fruit."

Canker, in *Surgery*, is a popular name for thoſe ſmall eroding ulcers which take place ſpontaneouſly in the cheeks, lips, and gums. This troubleſome ſpecies of ſore is probably connected for the moſt part with a ſtate of debility in the patient; as it is cured by tonic remedies given internally, accompanied with aceſcent diet and country air. It is alſo ſometimes uſeful to touch the ulcer with diluted acids, or a ſtrong ſolution of alum in water.

Canker, in *Veterinary Science*, a dreadful diſeaſe incident to the feet of horſes, and not of unfrequent occurrence, being very troubleſome to cure, and of unſightly appearance, exciting the ſame ſenſations in the mind of horror and diſlike, as do the loathſome animals whoſe names have been applied to it; hence the term *cancer* or *canker*, the *crab*, and the French term *crapaud* or *toad*, and in more ancient times *lupus* or the *wolf*.

We venture, however, to aſſert, that there is nothing ſpecifically poiſonous generated in the ſores of this deſcription, as in the human cancer, though it has been ſo imagined by many; from having ourſelves been frequently inoculated with the ſecretions from theſe ſores, (as have, no doubt, thouſands of others,) without, perhaps, an inſtance of any contagion ariſing from it; nor in the cure is there any ſpecific neceſſary, as in the cancerous, rabid, or venereal poiſonous ulcers.

It may be defined, perhaps, as a ſimple ulceration of the *corniferous*, or horn-bearing parts of the foot, attended with more or leſs weakneſs of the parts in forming horn, and generally of irritation from the horny edges ſurrounding the ſore; nor in the indications of cure is there any ſpecific neceſſary, as we have before obſerved; but the greateſt diligence and attention are requiſite in deſtroying thoſe cauſes of irritation, and in procuring and encouraging the natural growth of the horn over the expoſed parts, which, in old caſes, is found difficult enough.

In deſcribing the ſituation and appearance of this diſorder, we may obſerve, that all parts of the foot that are covered with horn may become the ſeat of this complaint, and its appearance will vary indefinitely, depending upon the greater or leſs degrees of weakneſs of the ſore, or irritation from the ſurrounding horn. The moſt uſual appearance, however, is a light, puffy, fungus, eaſily bleeding when touched, and riſing higher than the edges of the ſurrounding horn, giving out a thin watery diſcharge, with a diſpoſition in the ulcer to ſpread and run under the contiguous horn, and if not timely checked, it will extend itſelf over the whole foot, when the hoof falling off the horſe is neceſſarily loſt. On the other hand, where the proper means of correcting this ulceration are uſed, the contiguous horn is removed, the fungus is reduced, the parts become dry, horn again extends itſelf over the diſeaſed ſurface, and the foot becomes as perfect as it was before.

The time often required to correct the morbid diſpoſition in the part itſelf, and afterwards in procuring the natural growth of the horn, is ſo truly tedious, as, in very bad caſes, to make the expences of keep and cure more than overbalance the value of the horſe, and it would be to the diſadvantage of his proprietor to attempt it; in other caſes it is ſo eaſily ſubdued as to be well worth the time and expence of curing.

The narrative of a caſe or two will be a more impreſſive way of deſcribing the treatment of this complaint than any expoſition in general terms; and for this purpoſe we ſhall ſelect a ſucceſsful and an unſucceſsful caſe, ſuch as they occurred to us; and here let me remark, in doing that juſtice, we wiſh to hold an example of to every one in theſe matters, that among the ſhoeing-ſmiths there are many who take great pride in the cure of this diſorder, and whoſe practice, pretty much confined to this object, has rendered very expert; and as much depends on the adroit uſe of the drawing-knife in removing the horn from the ulcerated parts, they would have vaſtly the advantage over a young practitioner in this reſpect, though in other reſpects their treatment ſhould be the ſame, though theſe have ſometimes failed in bad caſes, or the long protracted cure has rendered it of no real advantage to the proprietors. The diſeaſe, we may obſerve, is almoſt always artificially induced, and may be prevented, which is of vaſtly more advantage to know than the mode of its cure.

The foot of the horſe may be conſidered as partaking ſomewhat of the nature of a gland, which is giving out and ſecreting horn, and whoſe ulceration will be attended with other phænomena than occur in the ulceration of fleſhy, or other parts of the animal ſtructure, and this peculiarity will render a different treatment neceſſary.

The following is a ſtatement of the treatment of a ſucceſsful caſe of this diſorder, with ſome obſervations as the caſe proceeds.

A black draft horſe that had been under the care of a ſhoeing-ſmith about nine or ten months to be cured, without ſucceſs, was put under our care in a truly deplorable condition. The ſole and frog were almoſt one extended ſurface of diſeaſe, ſecreting a white curdy fluid, which was poured out in great abundance about the ſides of the frog: this fluid was probably formed of the union of lymph, and the veſſels throwing out imperfect horn which became partially diſſolved in it; the ſame appears to be ſecreted in running thruſh, and if allowed to remain long on the part, becomes highly fetid.

The edges of the horn encircling the ſore were found to be detached, undermined, and black within; theſe were every where removed by thinning away the horn with a ſharp drawing knife, and when pared ſo thin and ſoft that the drawing knife would no longer lay hold of it, a lancet blade made rather ſtronger than thoſe uſually are for bleeding, and ſtuck in a handle, was uſed for thinning away the remaining part, and to diſſect ſmall bits of horn in ſituations where the drawing knife would not conveniently reach. This tedious proceſs was purſued on every ſide of the ſore which was found to extend to the wall of the foot, and took up a conſiderable time, the effuſion of the leaſt blood being cautiouſly avoided, as this would flow over and obſcure the parts to be cut. The foot was then ſmeared over with egyptiac, or the cupreous acetite, and honey, boiled together, though we found it equally, or ſuperiorly efficacious for this purpoſe when made of blue vitriol and treacle, at a much leſs expence, which may be acceptable information to thoſe who may have to uſe a large quantity of it: over this dreſſing, pledgets of tow dipped in tar and plentifully ſoaked with it are laid, till they cover it to a conſiderable depth. A hollow ſhoe having been previouſly tacked on by a few nails, an iron plate is paſſed under it, and this is faſtened in by iron ſplents between it and the ſhoe, and driven moderately tight with a hammer: ſimilar dreſſings are applied to the heels and ſides of the foot if requiſite, and then bound on tight by tar cords. Theſe dreſſings require to be removed every 48 hours, or when the diſeaſe is very virulent, every day: if on removing the dreſſings they appear tolerably free from moiſture, it is a favourable ſign. If the foot reeks, and the dreſſings appear drenched with perſpiration, little or no permanent horn will be found to have formed; if, on the contrary, the parts are doing well, the ulcer will appear almoſt dry, with a brown ſcale of horn formed upon its ſurface, which will generally ſhell off of itſelf, if not removed, and is beſt removed, and this for ſeveral ſucceſſive times, till the parts acquire the requiſite ſtrength for ſupporting the horn that is formed, which ſhould however be kept as thin as poſſible for a conſiderable time, that it may not irritate and exfoliate again. The ſurface that was undermined, and from whence the horn had been recently removed, will be found the next day to have ſwelled very much into a ſort of more healthy fungus, and on the ſurface of which, horn will begin to form; this being removed, another layer beneath this takes place, and ſo on till it reaches the natural foot. By this curious proceſs nature ſeems to acquire room, and avoids that compreſſion which the immediate formation of horn on the ulcer would occaſion. The parts of the ſore that were ſubject to irritation may be known by the thin diſcharge, and the riſing ſoft bleeding fungus; and the points of horn irritating them muſt be carefully removed to a conſiderable diſtance.

The firſt horn that forms, eſpecially of the ſole and frog, readily peels off, and exhibits underneath ſmall white fibres, by which it adhered; the ſecond coat is more firmly attached; and in recent caſes where the powers of the foot are not weakened, will adhere and become perfect horn; but in old caſes, it is requiſite often to remove it, or thin it down with the knife, and to keep it ſoft and pliant with tar dreſſings to prevent irritation and exfoliation.

Some, inſtead of egyptiac, apply dry powdered verdigreaſe to the ſore; others, butter of antimony; and ſome touch the ſurface with lunar cauſtic; others, again, uſe dilute nitrous acid, or marine acid; and ſome are fond of red lead boiled down, and mixed with the egyptiac, as making it more drying: theſe irritating meaſures, though of good effect at firſt, may be carried too far, and do miſchief, and weaken the parts too much: it is of more conſequence to carefully remove all external irritation from the ſurrounding horn, and the employing of uniform, regular, and ſtrong, but not exceſſive preſſure, which, if aſſiduouſly followed with the milder application of tar, are equal to the cure of moſt caſes, except ſuch as from long diſeaſe have become ſo deſtroyed and weak, as not to be capable of forming, or afterwards holding horn upon them, or, as is ſometimes the caſe, that the coffin-bone has been injured, and an exfoliating portion of it keeps up the ſore, in ſpite of every endeavour to heal it, till this is removed, as we have met with in two inſtances. This injury of the coffin-bone may ariſe from a nail driven by accident out of its courſe into the ſide of the foot, and which, entering the bone, ſplinters and deſtroys a portion of it; or from the remedies uſed being of a too corroſive nature, or too violent preſſure, that ſhall have deſtroyed the ſurface of it, which dying, acts as an extraneous body in preventing the parts from healing; or the horſe, from ſtamping violently on the unprotected bone, from pain or otherwiſe, ſhall fracture its thin edges, and thus keeping up an irritation which ſhall defy every attempt of cure till theſe are removed, each of which we have ſeen caſes of in the courſe of our practice; we may juſt remark, that where there is an exfoliating portion, it is beſt to remove it as early as poſſible, without waiting the tedious proceſs of natural exfoliation: the wound thus formed being then of the nature of a freſh wound, will more readily heal, a practice, we believe, firſt recommended by that truly great character, Mr. John Hunter.

The above remedies alſo may be occaſionally changed for each other with advantage, as the long continued application of one thing occaſions it to loſe its effect; and one agrees beſt with one ſubject, another with another, for which there can be no rule laid down.

By purſuing the above means ſteadily and uniformly for about nine months, the above tedious and deſperate caſe was cured, and every part of the foot covered with horn: the horſe was then turned to graſs to encourage the more rapid growth of the horn. On his return from graſs he was put to work, but ſuddenly died in a few months after of a liver complaint, which afforded an opportunity we had much ſought for of examining the condition of the coffin-bone after a long exiſtence of this complaint upon it, and alſo whether nature would reſtore the loſt foliated ſubſtance of the hoof; and on examination, the foliated horn had been in a great meaſure repaired, and was growing down quite perfect; having covered two-thirds of the inſide of the hoof where the canker had exiſted, and where it terminated, there was ſeen a ſmooth ſort of cartilaginous ſurface on the inſide of the hoof, and a ſimilar one attached to the foot, ſo that theſe laid in contact with each other without *laminæ*.

The ſole which is leſs organized in its ſtructure than the wall of the hoof, had no perceptible difference from the original ſole. If the coronary ring and origin of the *laminæ* had been deſtroyed, we ſhould in that caſe doubt the poſſibility of their reproduction; for in this caſe, the coronary ring had been cautiouſly preſerved. The coffin-bone had ſuffered greatly by the diſeaſe being conſiderably diminiſhed on the ſide on which the ſore had exiſted, and was become very porous, rough, and uneven; on its upper part near the coronary ring, a rough elevation of bone had been thrown out, of the ſize of a pea, ſuch as is depoſited in ſplints and ſpavins, being whiter and of not ſo denſe a texture as the natural bone. The channel of the artery had alſo a thin white oſſeous depoſite running to the inſide of the heels of the coffin-bone, even where no ſore had exiſted.

In the courſe of the treatment of this diſeaſe in different ſubjects, we have had recourſe to many different meaſures for keeping on the dreſſings to the foot; among others for this purpoſe we had made a leather boot, laced on its ſides, with a wooden ſole, defended at bottom by a thin ring of iron; this boot afforded the requiſite preſſure, but kept the foot, as we found by experience, too hot and moiſt, ſo that the horn was no ſooner formed than it again exfoliated.

Flannel bandages were found to be ſubject to the ſame inconveniences. Shoes made with ſmall hooks to the ſides, paſſing the bands over the coronet, could not be applied for any length of time, from the ſkin of the coronet ulcerating from the preſſure: we found on the whole nothing ſurpaſs the application of pledgets of tow dipped in tar and tied round the foot, (when the ſides were affected) with tar. An iron clip turned up from the ſhoe and paſſing parallel to the hoof was alſo found convenient when the ſore was not extenſive.

The laſt point is generally by far the moſt difficult to heal on the ſide of the foot; it will be found in general to be about oppoſite the circular artery of the coffin-bone, or its foramen: in the ſole the moſt difficult point is the heel, and the junction of the ſides of the frog with the ſole: to get at theſe moſt conveniently, tow rolled up pretty tight between the hands, then immerſed in the dreſſing, and thruſt into the cavity, will be found a convenient way of getting at it; another roll being laid over this, and another till we arrive at the level of the ſole, when a general pledget is applied over the whole.

At other times we thought it more convenient and advantageous, in ſole caſes, to paſs the iron plate under the ſhoe, and then ram it full by puſhing in the dreſſings through the openings of the heels.

If there be much moiſture in the dreſſings, the caſe rarely goes on well. The plentiful uſe of tar ſeems to have the power of ſuppreſſing, in ſome manner, this tranſudation, and cannot be too much attended to, as it ſerves alſo to keep the wet from it, if the horſe be uſed on the road.

A dry looſe place is better in the cure of this complaint for the horſe, than ſtanding conſtantly in one poſition in a ſtall, where eſpecially if it be in the hind legs, the blood accumulates with too much force from the declivity of the ſtall, their poſition being much lower than the reſt of the body.

Exerciſe, if the lameneſs is not ſo great as to forbid it, is much to be recommended, and the occaſional uſe of phyſic, eſpecially where the horſes ſtand ſtill; a rowel alſo may be had recourſe to with advantage, eſpecially if there be any diſpoſition to greaſe.

The frog, we have thought, appeared to be weaker in its powers of forming horn than the ſole, and this than the wall; and the firſt horn is more apt to be undermined and exfoliate from this part, though it may appear fair to the eye: cells containing a white ſemifluid matter alſo ariſe under it and that of the ſole, and are often the attendant of theſe exfoliations.

The cooler the foot can be kept, the more progreſs is made in the cure; therefore, much dreſſing or much covering is not ſo well, and water, though highly prejudicial, if applied for a conſtancy, yet may be uſed to waſh the foot with, and afterwards being well wiped dry, the dreſſings are applied, as we have thought, with good effect. In ſome caſes, where the fungus riſes higher than the horn, and it may be an object to ſave the horn, it will be better to attack the fungus by carefully paring it with a knife till blood appears, and then uſe the deſiccatives and preſſure; at any rate by this means, leſs of the horn need be removed, as we get at it cloſer to the fungus than in the other caſe; and it is always of conſequence where it can be done, to ſave all the horn poſſible, on account of its ſlow growth.

In diſſecting away the offending points of horn, we have found it uſeful to obſerve the rule of beginning in the moſt depending parts of the foot, that if the blood ſtarts, it ſhall not obſcure the parts you are next to come to, as it would do if you commenced differently. If inadvertently a veſſel is opened that is troubleſome, it is moſt readily ſtopped by the point of the cautery, without affecting the other part.

A kind of canker that is truly difficult of cure is the following.—A large draft horſe that had occaſionally been dreſſed by the ſmiths for more than a twelvemonth, had a canker of the near hind foot, with the following appearances: the frog was large and fleſhy, with a ſmooth red ſurface that would form a hard ſhell of horn, looſely attached and quickly exfoliating; the ſole every where bare of horn, having threads or fibres of conſiderable length, and hardened only at their extremity, their roots being inundated with a white milky ſecretion. After endeavouring ineffectually to harden theſe into horn, we cut them cloſe off with a pair of ſciſſars, and found that we made more progreſs upon the diſorder: the parts, however, were ſo weak, that they appeared unable to retain the horn they had formed, and after ſeveral exfoliations of this ſort, finding that little ground had been made, from the vicious diſpoſition of the animal, probably made ſo by the long pain he had been expoſed to, and the time it conſumed as well as the aſſiſtance it required, we determined to abandon the caſe. Two or three of ſuch caſes have we ſeen, out of about twenty, ſome of which have been eaſily cured in a few weeks.

Having given ſome account of the diſeaſe itſelf, it will now be right to conſider what is its cauſe, and if it can be prevented, for we fully concur in the words of Vegetius: (lib. 2. c. 58.) "preſtantius concilium eſt pedum tueri ſanitatem quam paſſionem curare;" preventive means are certainly the moſt wiſe, and after ſuch a deſcription of this diſorder, there is no one, we ſhould apprehend, that would not be anxious to avert it. We conſider the moſt prevailing cauſe of this complaint to be the running thruſh, which firſt only affects the cleft of the frog, but becoming aggravated, it gradually undermines the horn of the frog and ſpreads to its ſides, and from thence to the ſole, and ſo on to the wall and whole foot.

We remember one caſe where it appeared brought on by the greaſe, the diſcharge from which running down upon the frog, at length deſtroyed the horn, and brought on canker. Shaving the frog too cloſe with the buttreſs would occaſion this part to dry and crack, and wet getting into the cracks, and lodging there, would rot the frog and induce canker. Any wound of the frog or ſole not healing kindly at firſt by the blood, ſuch as a kennel nail wound, or any other deſcription of wound, becoming irritated by the ſurrounding horn, would form a canker; however, theſe are rare caſes compared with the one we have mentioned, viz. the running thruſh, the common ſource of the miſchief, which is certainly a conſequence of the frog being ſqueezed together by the contraction of the heels, and this again ariſes from the nailing of an iron ſhoe permanently to the foot, for an account of which, ſee articles, Foot *of the horſe*, and Farriery.

Such is the "brief chronicle" of our preſent experience in this diſeaſe, which, though avowedly imperfect, will ſerve as a more ſure baſis for receiving the facts of future labourers than the hitherto almoſt uſeleſs accounts of this terrible diſorder.

Canker is alſo a diſeaſe in dogs, which ſeizes their ears.

Canker, in hawks, breeds in the throat and tongue, occaſioned by foul feeding. It is cured by waſhing the mouth with honey and white wine boiled together, then ſtrewing it with chervil-powder.

Canker, *black*, in *Entomology* and *Huſbandry*, a ſpecies of caterpillar, which has been occaſionally deſtructive, in a very great degree, to the crops of turnips in Norfolk. The farmers in that county, obſerving great numbers of yellow flies among the turnips, previouſly to the appearance of theſe caterpillars, have been led to conclude, that the canker was the caterpillar ſtate of the yellow fly; and from their frequent appearance on the eaſtern ſea-coaſt it has been inferred, that they are not natives of this country, but that they come hither acroſs the ocean. Their deſtructive ravages, however, have not been confined within a few miles of the eaſtern coaſt; but they have extended more or leſs into the centre of the county. From the deſcription which Mr. Marſhall has given of them, it appears that they have four wings; that their antennæ are clubbed, and about one-third the length of the body, each being compoſed of nine joints; and that near the point of the tail of the female there is a black ſpeck outwardly fringed with hair, but which, opening longitudinally, appears to be the end of a caſe containing a ſting, about one-twentieth of an inch in length, which, on agitation, ſeparates into three one-edged inſtruments, with a ſpiral line or wrinkle winding from the points to the baſe, making ten or twelve revolutions, and giving them the appearance of being ſerrated. By means of theſe inſtruments, the female is ſuppoſed to depoſite her eggs in the edge of the turnip leaf, or ſometimes in the nerves or ribs on its under ſurface. The caterpillar has twenty feet (ſix of its legs being conſiderably long, and the other fourteen very ſhort); and in its firſt ſtage is of a jet black, deſtitute of hair, but covered with innumerable wrinkles. Having attained its full ſize, it fixes its hinder parts firmly to the leaf of a turnip, or other ſubſtance, and breaking its outer coat or ſlough near the head, crawls out, leaving the ſkin fixed to the leaf, &c. The under coat, which now appears, is of a bluiſh or lead colour. The caterpillar in this ſtate continues to feed on the turnips for ſome days longer; it then altogether deſiſts from eating, and becomes covered with a dewy moiſture which ſeems to exude from it in great abundance, and which, being of a glutinous nature, appears to form its chryſalis coat. Mr. Marſhall concludes from the genuine characters of the fly, that it is *tenthredo* of Hill. See Tenthredo and Turnip. Phil. Tranſ. vol. 73. p. 227, &c.

CANNA, in *Botany*, (Heb. קנה Kane, a reed, whence our Engliſh word Cane is indiſputably derived. Καννα is interpreted in the Greek Lexicons ψιαθος, a mat, or according to Heſychius, the plant of which mats are made. It is larger than arundo and leſs than calamus,) Linn. Gen. 1. Schreb. 1. Willd. 1. Gært. 41. Juſſ. 63. Vent. vol. 2. 203. (Cannacorus, Tourn. 192.) Indian flowering reed, or Indian ſhot. Baliſier, Fr. Claſs and order, *monandria monogynia*. Nat. Ord. *ſcitamineæ*, Linn. *cannæ*, Juſſ. *drymyrrhizæ*, Vent.

Gen. Ch. *Cal.* Perianth three-leaved, permanent; leaves lanceolate, erect. *Cor.* Monopetalous, ſix-cleft (eight-cleft; Saliſb.) three outer ſegments erect, larger than the calyx; three inner ſegments larger than the outer ones, two erect, one revolute, forming a kind of lip. *Stam.* Filament reſembling a petal, two-cleft; upper ſegment erect, bearing the anther; lower one revolute; anther linear, adhering to the edge of the upper ſegment of the filament. *Piſt.* Germ inferior, roundiſh, ſcabrous; ſtyle ſword-ſhaped, reſembling a petal, united at its baſe to the filament; ſtigma linear, adhering to the edge of the ſtyle. *Peric.* Capſule roundiſh-egg-ſhaped, crowned with the calyx, ſcabrous, three-furrowed, three-celled, three-valved; cells many-ſeeded. *Seeds* globular, affixed to a central receptacle.

Eſſ. Ch. Calyx three-leaved, corolla ſix-cleft, filament two-cleft; one ſegment revolute, ſtyle united at its baſe to the filament, capſule crowned with the calyx.

Obſerv. What is called the filament by Linnæus, Juſſieu, Ventenat, and La Marck, is conſidered by Schreber as a nectary, and by Saliſbury as conſtituting two other ſegments of the corolla.

Sp. 1. C. *indica*, Linn. Sp. 1. Gært. tab. 12. fig. 3. La Marck Illuſt. Pl. 1. Bot. Mag. 454. (Cannacorus, Rumph. Amb. 5. tab. 71. fig. 2. Katu-Bala; Rheed. Mal. 11. p. 85. tab. 43. Arundo indica latifolia, Bauh. pin. 19.) β Cannacorus ampliſſimo fol. flore rutilo; Tourn. Inſt. 367. γ C. *coccinea*, Hort. Kew. γ C. flore coccineo ſplendente, Tourn. Inſt. 367. δ C. *lutea*, Hort. Kew. β Cannacorus fl. luteo punctato, Tourn. Inſt. 367. Riv. tab. 112. "Leaves egg-ſhaped, acuminate at both ends, nerved." Linn. "Leaves broad-lanceolate, ſmooth beneath; ſegments of the corolla revolute, nearly linear; inner ones leſs." Saliſbury prod. *Root* thick, fleſhy, horizontal, divided into many irregular knobs. *Root-leaves* egg-ſhaped, a foot long, and five inches long in the middle, with many large, tranſverſe veins, prominent on the under ſide, running from the midrib to the ſides; and between each of them two ſmaller, parallel, pointed veins. *Stems* three or four feet high, ſimple, upright, herbaceous. *Stem-leaves* alternate, large, broad, egg-ſhaped, acuminate, ſheathings ſmooth. *Flowers* red, in an upright, terminal, rather looſe ſpike; almoſt ſeſſile, growing alternately, two or three together in the axil of a ſhort, ſpathaceous ſcale. A native of warm climates in Aſia, Africa, and America. Its leaves are uſed to cover houſes in Cayenne. Its root is regarded as diuretic and deterſive. Its ſeeds dye a beautiful but not durable purple. 2. C. *anguſtifolia*, Linn. Sp. Pl. "Leaves lanceolate, petioled, nerved." Perhaps only a variety of the preceding ſpecies, but lower and narrower; and one of the lateral ſegments of the petal is ſo bent as to become the middle one. A native of ſpongy ſhady places within the tropics. 3. C. *glauca*, Linn. Sp. Pl. (cannacorus glaucophyllus: Dill. Elth. tab. 59. fig. 69.) "Leaves lanceolate, petioled, nerveleſs." Linn. "Leaves narrow-lanceolate, even on both ſides; ſegments of the corolla ſpreading, inverſely egg-ſhaped; inner ones leſs." Saliſb. *Roots* large, ſtriking ſtrong fleſhy fibres deep into the ground. *Stems* ſeven or eight feet high. *Leaves* near two feet long, narrow, ſmooth, of a glaucous colour. *Flowers* large, pale yellow, in ſhort thick terminal ſpikes. *Seed-veſſels* larger and longer than in the preceding ſpecies, with fewer and larger ſeeds. Cultivated at Eltham by Dr. Sherard in 1732. Raiſed by Mr. Miller in 1733 from ſeeds ſent from Carthagena in New Spain, which produced ſtrong plants the firſt year, ſome of them flowering the ſame autumn. 4. C. *flaccida*. Saliſb. Prod. p. 4. Icon. ſtirp. rar. 3. (C. glauca β, Willd.) "Leaves narrow-lanceolate, even on both ſides: ſegments of the corolla flaccid, inverſely egg-ſhaped: inner ones larger." A foot and half high or more, (four feet, Mart.) reſembling C. glauca. *Root* horizontal, tuberous; fibres white, thick, fleſhy. *Stems* ſeveral, pale ſea-green, upright, ſimple, round, jointed, ſmooth, herbaceous, nearly, if not entirely, covered by the ſheathing petioles. *Leaves* from five to ſeven, pale ſea-green, alternate, ſhorter than the petioles or ſheaths, ſpreading, entire, with a very thin membranous edge, pointed at the end, very finely nerved, a little channelled above, keeled beneath, eſpecially towards the baſe. *Flowers* from one to three, pale yellow, ſcentleſs, rather nodding: bractes two under each germ, blunt, entire, permanent; the outer one preſſed cloſe to the germ, the inner one longer and narrower, often ſpreading and incurved: calyx-leaves unequal, entire, obtuſe: tube of the corolla much longer than the calyx, a little recurved; outer border a little longer than the tube, abruptly reflexed, deeply three-cleft; ſegments unequal, linear-lanceolate, entire, obtuſe, thicker; inner border longer than the outer one, deeply five-cleft, ſegments tender, flaccid, much curled at the edges, the outer ones narrow, and nearly cloſed, the inner ones (ſegments of the filament, Linn. &c.) broader, inverſely egg-ſhaped, emarginated; anther white, adhering to the edge of the inner ſide of the inmoſt ſegment, upright, linear, very minutely pointed, two-celled, opening in front; germ pale-green, oval, minutely tubercled: ſtyle very pale yellow, linear-ſpatula-ſhaped, ſmooth on both ſides, flat; ſtigma white, ſlightly pubeſcent. *Pericarp* and *ſeeds* ſimilar to thoſe of the other ſpecies. Saliſbury. A native of South Carolina, where it was found by Bartram. It is often miſtaken for C. glauca. 5. C. *juncea*, Willd. Retz Obſ. faſc. 1. p. 9. 2. 1. "Leaves linear, nerved." *Leaves* graſs-like, with five raiſed nerves, ſheathing at the baſe; thoſe near the root covered with capillary fibres, from ſeven inches to a foot long. *Flowers* of a duſky rufous colour. *Pericarp* rough, with pointed tubercles. Retz. A native of China.

*Propagation and Culture.* All the ſpecies are perennial, and with proper management will continue many years: but as young plants always flower better than old roots, it is beſt to raiſe them annually from ſeeds which ſhould be ſown in a hot-bed in the ſpring. When the plants are fit to remove, they ſhould be tranſplanted into ſeparate ſmall pots, filled with rich kitchen garden earth, and plunged into a moderate hot-bed of tanners-bark. In warm weather they ſhould be ſupplied with freſh air every day and frequently watered. As they ſoon grow large, they ſhould be ſhifted into larger pots, and part of them plunged into the ſame hot-bed; the reſt may be placed abroad in June in a warm ſituation with other exotic plants. Thoſe which are placed in the hot-bed will be ſtrong enough to flower well in the ſtove in the following winter: but thoſe in the open air will not flower before the following ſummer. In the beginning of October, they muſt be removed into the ſtove. The variety β of C. indica, which is a native of Carolina and ſome of the other northern ſtates of America, being hardier, ſhould be more early enured to the open air, where it may remain till the froſt begins. It ſhould be then removed to the green houſe, and during the winter ſhould have but little water. In the beginning of May it may be turned out of the pot, and planted in a dry ſoil on a warm ſouth border, where it will produce flowers annually. Miller.

Canna, in *Commerce*. See Cane.

Canna, in *Ancient Geography*, a ſmall town of Aſia Minor, in the Eolide. Mela.—Alſo, a town of Cappadocia, in Lycia. Ptolemy.—Alſo, a place of Aſia, between Cyrra and Edeſſa. Anton. Itin.

CANNABA, a place of Aſia, in Syria, upon the route from Nicopolis to Edeſſa. Anton. Itin.

CANNABICH, in *Biography*, a ſpirited and maſterly compoſer of ſymphonies, of the Manheim ſchool, contemporary with Stamitz and Holtzbaut, about the middle of the laſt century. He was the moſt eminent ſolo player on the violin of his time: and his ballet of the deſcent of Hercules into the infernal regions, is a moſt beautiful production.

CANNABINA, in *Botany*, (folio tripartitim diviſo. C. Bauh. pin. 321.) See BIDENS TRIPARTITA.

CANNABINA, (folio non diviſo, ibid.) See B. CERNUA.

CANNABINA, (indica. Magn. Hort. 40. tab. 40.) See VERESINBA ALATA.

CANNABINA, Tourn. Cor. 52. tab. 488.) See DATISCA CANNABINA.

CANNABIS, (κανναβις, Herod. Dioſcor. It is not mentioned by Theophraſtus.) Linn. gen. 1115. Schreb. 1522. Gært. 463. tab. 75. fig. 1. Tourn. Inſt. 535. tab. 309. Juſſ. 404. Vent. vol. iii. 536. Claſs and Order, *diæcia pentandria*. Nat. Ord. *Scabridæ*, Linn. *Urticæ*, Juſſ.

Gen. Ch. Male. *Cal.* perianth five-cleft; ſegment oblong, acuminately obtuſe, concave. *Cor.* none. *Stam.* filaments five, capillary, very ſhort; anthers oblong, four-cornered. Female. *Cal.* perianth one-leafed, oblong, acuminate, opening longitudinally on one ſide, permanent. *Cor.* none. *Piſt.* germ very ſmall; ſtyles two, very long; ſtigmas acute. *Peric.* the permanent calyx cloſely covering the ſeed. *Seed*, nut globular, depreſſed, two-valved.

Eſſ. Ch. Male. Calyx five-cleft; corolla none. Female. Calyx one-leafed, entire, opening on one ſide; corolla none; ſtyles two; nut two-valved, within the cloſed calyx.

Sp. 1. C. *ſativa*, Linn. Sp. Pl. Mil. fig. tab. 77. Bauh. Hiſt. i. fig. 448. Ger. Emac. 708. fig. 1, 2. Lam. Ill. Pl. 814. Hemp. Chanvre, Fr. "Leaves oppoſite." *Root* annual. *Stem* from ſix to eight feet high or more, upright, obſcurely quadrangular, a little hairy. *Leaves* petioled, digitate; leaflets five or ſeven, lanceolate, acuminate, ſerrated, outer ones the ſmalleſt. *Male flowers* in ſmall looſe racemes or ſpikes at the ends of the ſtem and branches. *Female flowers*, axillary, ſolitary, very ſmall. Both kinds ſometimes occur on the ſame plant, but always one of them very few in proportion to the other. All the old authors ignorantly call the male flowers female, and vice verſa. It is ſaid by Herodotus to be a native of Scythia. According to Linnæus it grows wild in the Eaſt Indies. Thunberg ſays it grows here and there in Japan. Gmelin found it in Tartary, and Father Hennepin among the Illinois, in North America. From long cultivation it is almoſt naturalized in the ſouth of France, Italy, &c. An oil is extracted from its ſeeds. The ſeeds themſelves are thought to be good for poultry, and to cauſe hens to lay a larger quantity of eggs, but ſhould be given to ſmaller birds with caution, and mingled with other ſeeds. It has been ſaid, that if bullfinches and goldfinches feed upon them too plentifully, the red and yellow of their plumage is changed to a total blackneſs. For the propagation and culture of this plant, the various proceſſes which it undergoes in the hands of the manufacturer, and the uſes to which it is applied, ſee HEMP. 2. C. *indica*, Lam. Encyc. (C. ſimilis exotica, Bauh. pin. 320. C. peregrina, Moriſ. Hiſt. iii. p. 433. n. 2. Kalengi-Cansjava, Rheed. Mal. 10. p. 119. tab. 60. Tsjern-Cansjava, Ibid. tab. 61. Dakka or Bangua of the Indians. *β*. With a taller ſtem. Rumph. Amb. v. p. 208. tab. 77. "Leaves alternate." *Stem* nearly cylindrical, ſmaller, more branched, and harder than that of the preceding ſpecies. *Leaves* all conſtantly alternate; leaflets linear-lanceolate, very ſharp-pointed; in the male plants five or ſeven, in the female ones commonly but three, on a petiole; near the top entirely ſimple. A native of the Eaſt Indies. Its hard ſtem and thin bark render it incapable of being wrought into filaments and ſpun like common hemp. It has a ſtrong ſmell, a little like that of tobacco. The Indians make of its bark and the expreſſed juice of its leaves and ſeeds, a liquor which has an intoxicating quality; and if they wiſh to produce a ſtronger effect, they either chew or ſmoke its dried leaves mingled with tobacco. A little nutmeg, cloves, camphor, and opium, mixed with its juice, form the compoſition which the Indians call *majeh*, and which, according to Cluſius, is the ſame as the malach of the Turks.

CANNACORUS. See CANNA.

CANNÆ, the ſecond order of the fourth claſs of the natural orders of Juſſieu, with the following character. *Calyx* (corolla, Linn.) ſuperior, coloured; divided into ſeveral, often ſix, petal-ſhaped, generally unequal and irregular ſegments; with three others exterior and ſmaller, putting on the appearance of an external calyx, (the proper calyx, Linn.) *Stamen* one; filament inſerted into the baſe of the ſtyle, often flat and petal-ſhaped; anther adhering, ſimple, or rarely double. *Germ* inferior; ſtyle ſimple, often thread-ſhaped; ſtigma ſimple or divided. *Capſule* inferior, three-celled, moſt frequently three-valved, and many-ſeeded. *Root* often tuberous, creeping. *Stem* herbaceous, covered with the ſheathing petioles. *Leaves* alternate, ſheathing, younger ones convolute, ſome many-nerved, others ſending out parallel nerves from each ſide of a ſimple midrib. *Flowers* in ſpathes, often growing on a cauline, or radical ſpadix. The genera aſſigned to this order by Juſſieu are catimbium, canna, globba, myroſma, amomum, coſtus, alpinia, maranta, thalia, curcuma, and kæmpferia.

CANNÆ, in *Ancient Geography*, a ſmall town of Italy, in Apulia, ſeated on the river Aufidus, now called Ofanto. The Latins uſe the plural appellation for this city, probably from its conſiſting of diſtinct parts, built on different eminences. The Greeks, and Polybius in particular, called it Καννη, in the ſingular number. This place has been rendered famous in hiſtory by the battle fought in its vicinity between the Carthaginians and the Romans, in the year of Rome, 538, B. C. 216. For ſome time previous to this battle, Hannibal, the Carthaginian general, had, by various movements and ſkirmiſhes, endeavoured to bring Fabius, the wiſe and wary Roman dictator, to a deciſive conteſt. He well knew that inaction and delay were the principal evils he had to fear, and the diſtreſs occaſioned by want of proviſions and money made him anxious to provoke the Romans to an engagement. Fabius, on the other hand, duly apprized of the ſituation of his adverſary, adopted every prudent meaſure for protracting the war, and ruining his enemy by delay. Some trivial ſucceſſes which were gained by the Romans in their encounters with the Carthaginians, increaſed the confidence both of the army and of the people: and forgetting their former defeats, they began to imagine that the enemy maintained his ſtation in Italy, by the permiſſion, by the timidity, or by the exceſſive caution of their leader. Minutius, the general of the horſe, having alſo, in the abſence of the dictator, obtained ſome ſlight advantage over the foraging parties of Hannibal, the army and the people were confirmed in this opinion, and the reputation of Fabius was greatly ſunk in their eſtimation. But as he could not be ſuperſeded till the uſual term of his office expired, the ſenate and people adopted a meaſure, which they hoped would induce him to reſign. They raiſed the general of the horſe to an equal command with the dictator, and left them to adjuſt their reſpective pretenſions. The Roman dictator, inſtead of raſhly and indignantly withdrawing his ſervices in a moment of danger, continued to ſerve under this diminution of rank and command, and magnanimouſly overlooked the inſults with which the people had requited the ſervice he was rendering to his country. Minutius being now aſſociated with the dictator, in order to be free from the reſtraints of a joint command, and from the wary counſels of his colleague, deſired, as the moſt proper mode of adjuſting their pretenſions, to divide the army between them. In this new ſituation he expoſed himſelf and his diviſion, by his raſhneſs, to the danger of being entirely cut off by the enemy; but being reſcued by Fabius, he acknowledged the favour he had received, and committing himſelf, with the whole army, to the conduct of his colleague, he left this cautious officer, during the remaining period of their joint command, to purſue the plan which he had formed for the war, and to which, without overbearing interference, he determined to adhere. The people, and the ſenate, however, were not diſpoſed to acquieſce in what they conceived to be the languid and dilatory meaſures which Fabius was inclined to purſue. Having reſolved to augment the army in Italy to eight legions; which, with an equal number of the allies, amounted to 80,000 foot and 7200 horſe, which they conceived would be a force more than ſufficient to counteract that of the Carthaginians, which conſiſted of 40,000 foot, and 10,000 horſe; they intended, on occaſion of the approaching election of conſuls, to chuſe men, not only of reputed ability, but of deciſive and reſolute counſels. Accordingly, they elected C. Terentius Varro, ſuppoſed to be of a bold and dauntleſs ſpirit; and, with a view of tempering his ardour, they joined with him in the command L. Æmilius Paulus, an officer of approved experience, who had formerly obtained a triumph for his victories in Illyricum, and who ſtood high in the confidence of the ſenate, as well as in that of the people.

The autumn before the nomination of theſe officers to the command of the Roman army, Hannibal had ſurpriſed the fortreſs of Cannæ, whither the Roman citizens of that quarter had retired with their effects, and where they had collected conſiderable magazines and ſtores. This, among other circumſtances, determined the ſenate to hazard a battle, and to furniſh the new conſuls with inſtructions to this effect. Theſe officers, having opened the campaign on the banks of the Aufidus, advanced by mutual conſent within ſix miles of the Carthaginian camp, which covered the town of Cannæ. Here they differed in their opinions; and a compromiſe was made by an agreement, that each of them ſhould alternately take the command for a day. Varro, in oppoſition to the ſentiments of his colleague, propoſed to give battle on the plain, and for this purpoſe, as often as the command devolved upon him, ſtill advanced on the enemy. In order to occupy the paſſage and both ſides of the Aufidus, he encamped in two ſeparate diviſions on its oppoſite banks, having his larger diviſion on the right of the river, oppoſed to Hannibal's camp. Still taking the opportunity of his turn to command the army, he paſſes with the larger diviſion to a plain, ſuppoſed to be on the left of the Aufidus, where, as the field was too confined to receive the legions in their uſual form, he preſſed them together, and gave the enemy, if he choſe it, an opportunity to engage. For the accommodation of his order to the extent of his ground, he contracted the head, and the intervals of his manipules or columns, making their depth greatly to exceed the front which they turned to the enemy. He placed his cavalry on the flanks, the Roman knights on his right towards the river, and the horſemen of the allies on the left. Varro, having thus arranged his force, and impelled by vanity, in conſequence of having obtained ſome ſlight advantages by ſkirmiſhes between the light horſe, or exaſperated by an inſult of the Numidians, who had purſued a body of Romans almoſt to the gates of the camp, determined to bring the conteſt to a ſpeedy concluſion. Paulus Æmilius diſapproved of the place which he had choſen for the ſcene of battle, but wiſhed to draw the enemy to a ſituation, where the infantry, in the number of which they exceeded, might have the greater ſhare in the action, whereas Hannibal's cavalry was in every reſpect ſuperior to that of the Romans; and remonſtrated againſt the precipitance of his colleague. Paulus Æmilius commanded the right of the Romans, Varro the left, and Servilius Geminus, the conſul of the preceding year, was in the centre. Hannibal, as ſoon as he ſaw the movement and diſpoſition of the enemy, haſtened to meet them on the plain which they had choſen for the field of action. He likewiſe paſſed the Aufidus, and with his left to the river and his front to the ſouth, formed his army upon an equal line with that of the enemy. He placed the Gauliſh and Spaniſh cavalry on his left facing the Roman knights, and the Numidians on his right facing the allies. The flanks of his infantry, on the right and the left, were compoſed of the African foot, armed in the Roman manner, with the pilum, the heavy buckler, and the ſtabbing ſword. His centre, though oppoſed to the ſelect portion of the Roman legions, conſiſted of the Gauliſh and the Spaniſh foot, variouſly armed and intermixed together. Aſdrubal commanded the left, Hanno the right, and Hannibal with his brother reſerved the command of the centre to himſelf. As the armies fronted north and ſouth, even the ſun, which roſe ſoon after they were formed, ſhone upon the flanks, and was no diſadvantage to either of them. Some difficulty has occurred in deciding which way each of theſe armies was turned; as the expreſſions of Polybius are ſaid by ſome to admit of a double meaning. His words are "*Βλεπȣσης δὲ της μεν των Ρωμαίων τάξεως πρὸς μεσημβρίαν τῆς δὲ τῶν Καρχηδονίων πρὸς τας ἄρκτȣς· ἑκατέροις ἀβλαπῆ συνέβαινε γινεσθαι τὴν κατὰ τὸν ἥλιον ανατολην.* Spectante meridiem Romanorum acie, Carthaginienſium verò ſeptentrionem, ambobus inoffenſis contigit eſſe ab ſolis ortu. Livy is charged by Chaupy with having miſinterpreted the paſſage of the Greek hiſtorian, who, according to his opinion, did not mean, that the Romans ſtood with their faces to the noon-tide ſun; but only that they were drawn up to the ſouth of the enemy. Livy's words are (lib. xxii. 46.) "Romanis in meridiem, Pænis in ſeptentrionem verſis." He affirms, moreover, that the topography of the plain, and the courſe of the river, agree with this explanation; and that if the legions had faced the ſouth, the runaways could not, after the defeat, have reached Canuſium and Venuſia, without paſſing through the whole victorious army. Salapia, Arpi, and Luceria, would have been their places of refuge. Swinburne inclines to truſt to the explanation of Livy, who was ſufficiently acquainted with the Greek language not to miſtake the meaning of an author whom he ſtudied and followed ſo cloſely; more eſpecially as, according to his ideas, the ſituation of the ground is in favour of the Roman hiſtorian; for exactly in that part of the plain where we know with moral certainty that the main effort of the battle lay, the Aufidus, after running due eaſt for ſome time, makes a ſudden turn to the ſouth, and deſcribes a very large ſemicircle. The Romans, we are to ſuppoſe, forded it at the angle or elbow, and placed their right wing on the banks; while the legions extended themſelves due eaſt, till the whole line came to face the ſouth. The Carthaginians croſſed in two places within the ſemicircle; and were drawn out in a line, that formed the chord of which the river was the arch; and therefore the way to Canuſium was open for the fugitives. Swinburne adds, that the ſcene of action is marked out to poſterity by the name of "Pezzo di Sangue," or field of blood. The peaſants, he ſays, ſhewed us ſome ſpurs and heads of lances lately turned up by the plough, and told us, that horſe-loads of armour and weapons had been at different times carried away from thence. Livy (l. xxii. 13.) and Plutarch (in Fab. p. 183.) inform us, that Hannibal, who knew how to avail himſelf of circumſtances, as a great captain, forgot nothing that could conduce to the victory. A wind peculiar to that region, called in the country the "Vulturnus," blew always at a certain period. He took care to draw up in ſuch a manner, that his army, facing the north, had it in their backs, and the enemy, fronting the ſouth, had it in their faces; ſo that he was not in the leaſt incommoded by it: whereas the Romans, whoſe eyes it filled with duſt, ſcarcely ſaw before them. The ſuperiority of numbers was greatly on the ſide of the Romans; but Hannibal reſted his hopes of victory on two circumſtances: firſt, on a motion to be made by his cavalry, if they prevailed on either of the enemy's wings; next, on a poſition he was to take with his centre, in order to begin the action from thence, to bring the Roman legions into ſome diſorder, and expoſe them, under that diſadvantage, to the attack which he was prepared to make with his veterans on both their flanks. The action accordingly began with a charge of the Gauliſh and Spaniſh horſe, who, being ſuperior to the Roman knights, drove them from their ground, forced them into the river, and put the greater part of them to the ſword. By this event the flank of the Roman army, which might have been joined to the Aufidus, was entirely uncovered. Having performed this ſervice, the victorious cavalry had orders to wheel at full gallop round the rear of their own army, and to join the Numidian horſe on their right, who were ſtill engaged with the Roman allies. By this unexpected junction, the left wing of the Roman army was likewiſe put to flight, and purſued by the African horſe; at the ſame time the Spaniſh cavalry prepared to attack the Roman infantry, wherever they ſhould be ordered on the flank, or the rear. While theſe important events took place on the wings, Hannibal amuſed the Roman legions of the main body with a ſingular movement that was made by the Gauls and Spaniards, and with which he propoſed to begin the action. Theſe came forward, not in a ſtraight line a-breaſt, but ſwelling out to a curve in the centre, without disjoining their flanks from the African infantry, who remained firm on their ground. By this motion, they formed a kind of creſcent convex to the front. The Roman manipules of the right and the left, fearing by this ſingular diſpoſition to have no ſhare in the action, haſtened to bend their line into a correſponding curve; and, in proportion as they came to cloſe with the enemy, charged them with a confident and impetuous courage. The Gauls and Spaniards reſiſted this charge no longer than was neceſſary to weaken the precipitant ardour with which victorious troops often blindly purſue a flying enemy. And the Roman line being bent, and fronting inwards to the centre of its concave, the legions purſued where the enemy led them. Hurrying from the flanks to ſhare in the victory, they narrowed their ſpace as they advanced, and the men who were accuſtomed to have a ſquare of ſix feet clear for wielding their arms, being now preſſed together, ſo as entirely to prevent the uſe of their ſwords, found themſelves ſtruggling againſt each other for ſpace, in an inextricable and hopeleſs confuſion. Hannibal, who had waited for this event, ordered a general charge of his cavalry on the rear of the Roman legions, and at the ſame time an attack from his African infantry on both their flanks: by theſe diſpoſitions and joint operations, without any conſiderable loſs to himſelf, he effected an almoſt incredible ſlaughter of his enemies. With the loſs of no more than 4000 Gauls, 1500 Spaniards and Africans, and 200 horſes, he put 50,000 of the Romans to the ſword. Polybius ſays the general loſs amounted to more than 70,000. The Carthaginians were ſo furious againſt the enemy that they did not ceaſe killing till Hannibal, in the greateſt heat of the conflict and ſlaughter, exclaimed ſeveral times, "Hold, ſoldiers, ſpare the vanquiſhed." The conſul Æmilius Paulus had been wounded in the ſhock of the cavalry; but when he ſaw the condition in which the infantry were engaged, he refuſed to be carried off, and was ſlain. "I have taken my reſolution," ſaid he. "I will expire upon theſe heaps of my dead ſoldiers: but do you take care not to loſe the time you have for eſcaping from the enemy, through an uſeleſs compaſſion. Go, and tell the ſenate from me to fortify Rome, and to make troops to enter it for its defence, before the victor arrives to attack it. Tell Fabius in particular, that I lived and died highly ſenſible and fully convinced of the wiſdom of his counſels." The conſuls of the preceding year, with others of the ſame rank, were likewiſe killed: of 6000 horſe only 70 troopers eſcaped with Varro. Of the infantry, 3000, or according to other accounts, 4000, fled from the carnage that took place on the field of battle, and 10,000, who had been poſted to guard the camp, were taken; others retired to Canuſium.

The unfortunate conſul with ſuch of the ſtragglers as joined him in his retreat, took poſt at Venuſia, and afterwards at Canuſium, where he joined a conſiderable number of thoſe that had eſcaped; and with a noble confidence in his own integrity, and in the reſources of his country, put himſelf in a poſture to reſiſt the enemy, till he obtained further inſtructions and reinforcements from Rome. On his return to the city, the ſenate, conſcious that he had acted at Cannæ by their own inſtructions, and, that influenced by the motives that animated the whole Roman people, he had diſdained, with a ſuperior army, to ſtand in awe of his enemy, or to refuſe him battle upon equal ground, went out in a kind of proceſſion to meet him; and overlooking his temerity and miſconduct in the action, they attended only to the undaunted aſpect which he preſerved after his defeat, and returned him thanks for not having deſpaired of the commonwealth. From this time they continued their preparations for war with all the dignity and pride of the moſt proſperous fortune. They refuſed to ranſom the priſoners who had been taken by the enemy at Cannæ, and treated with ſullen contempt, rather than ſeverity, thoſe who by an early flight had eſcaped from the field; and when they were petitioned to employ them again in the war, they replied, "we have no ſervice for men who could leave their fellow-citizens engaged with an enemy." On the part of Hannibal, this victory was complete; but his ſubſequent inactivity ſaved Rome and her dominions. Many, and Livy amongſt the reſt, condemn Hannibal for his delay in properly improving this ſignal ſucceſs, as a capital error. But others, reſtrained by the authority, or rather the ſilence of Polybius, have forborne from cenſuring the conduct of the Carthaginian general. He allows, indeed, that the Carthaginians entertained hopes of carrying Rome on the firſt aſſault; but he does not explicitly declare his own opinion concerning the meaſures which might have been proſecuted in reſpect to a city very populous, extremely warlike, well fortified, and defended by a garriſon of two legions. He does not ſo much as intimate that ſuch a project was practicable, or that Hannibal was to be blamed for not having attempted it. It ſhould be conſidered, that after the battle he had not more than 26 or 27 thouſand foot, who were in a condition to act; and that number could not ſuffice either for forming the circumvallation of a city of ſuch extent as Rome, with a river running through it, or for attacking it in form, without machines and other implements neceſſary in a ſiege. The victory at Cannæ afforded to Hannibal a very conſiderable booty: but except men, horſes, and a little ſilver which was principally upon the furniture of the horſes, he abandoned all the reſt to the ſoldiers. After the battle of Cannæ, Hannibal took up his winter quarters at Capua, which ſee. Polybius, iii. 262-267-298. Livy, xxii. 43-44-54. Plut. in Fab. 182-184. Rollin's Anc. Hiſt. vol. i. Rollin's Rom. Hiſt. vol. iii.

The plains on which the battle of Cannæ was fought, have more than once, ſince the Punic war, afforded a ſcene of warfare and blood. Melo of Bari, after raiſing the ſtandard of revolt againſt the Greek emperors, and defeating their generals in ſeveral engagements, was at laſt routed here, in 1019, by the catapan Bolanus. Out of 250 Norman adventures, the flower of Melo's army, no more than ten eſcaped the ſlaughter of the day. In 1201, the archbiſhop of Palermo and his rebellious aſſociates, who had taken advantage of the nonage of Frederick of Swabia, were cut to pieces at Cannæ by Walter de Brienne, ſent by the pope to defend the young king's dominions. The remaining traces of the town of Cannæ are very faint; and conſiſt of fragments of altars, cornices, gates, walls, vaults, and underground granaries. It was deſtroyed, as we have already obſerved, the year before the battle; but being rebuilt, it became an epiſcopal ſee in the infancy of Chriſtianity. It was again reduced in the 6th century; but ſeems to have ſubſiſted in an humble ſtate many ages later; for we read of its contending with Barletta for the territory which till that time had been enjoyed in common by them: and in 1284, Charles the firſt iſſued an edict for dividing the lands to prevent all future litigation. The proſperity of the towns along the coaſt, which increaſed in wealth and population by embarkations for the cruſades, and by traffick, accelerated the annihilation of the inland cities; and Cannæ was probably abandoned entirely before the end of the 13th century. It is now an inconſiderable place, with a titular ſee, in the country of Bari. Swinburne's Travels, &c. vol. i.

CANNAGARA, a town of India, placed by Ptolemy on the other ſide of the Ganges.

CANNAR, or Cannatum, a promontory of Africa, in the Mediterranean Sea, in Mauritania Tingitana, according to the Itinerary of Antonine.

CANNARES, Indians of the province of Quito, in Peru. They are well made and very active; they wear their hair long, which they weave and bind about their heads, in form of a crown. Their clothes are made of wool or cotton, and they wear fine-faſhioned boots. Their women are handſome and fond of the Spaniards; they generally till and manure the ground, whilſt their huſbands at home card, ſpin, and weave wool and cotton. Their country had many rich gold mines, which have been drained by the Spaniards. The land bears good wheat and barley, and has fine vineyards. The magnificent palace of "Theomabamba" was ſituated in the country of the Canares.

CANNAVAROLA, in *Ornithology*, the name aſſigned by Aldrovandus to the babbling warbler, Motacilla Curruca of Linnæus.

CANNAVERAL, Cape, in *Geography*, the extreme point of rocks on the eaſt ſide of the peninſula of Eaſt Florida, having the Moſquitos inlet N. by W. and a large ſhoal S. by E. This was the boundary of Carolina by charter of Charles II. N. lat. 28° 35'. W. long. 81° 9'.

CANNAYAH, a village of the north ſide of Waſhington iſland, on the N.W. coaſt of North America.

CANNEL-Coal. See Coal.

CANNELÉ, in *Zoology*, a ſpecies of biped reptiles in the arrangement of De la Cepede, in the firſt volume of his "Hiſtory of oviparous Quadrupeds and Serpents." The other ſpecies of this genus is the ſheltopuſik, deſcribed by Pallas in the Peterſburgh Tranſactions.

The cannelé is an animal lately diſcovered in Mexico by M. Vélaſques, and brought into France by the viſcounteſs de Fontanges. Its whole length is 8½ inches, and its diameter the third of an inch; the abdominal ſemi-rings are 150, and the tail-rings 31; the thickneſs of the whole body is nearly equal; the legs, one-third of an inch long, are cloſe to the neck, and the feet have each four toes furniſhed with nails. The cannelé ſeems to have a near reſemblance to the amphiſbæna of Linnæus, and perhaps, when it is better known, it may be found to belong to that genus; though, at the ſame time, the legs juſtify the genus as eſtabliſhed by the count De la Cepede.

CANNEQUINS, in *Commerce*, white cotton cloths brought from the Eaſt Indies. They are a proper commodity for trading on the coaſt of Guinea, particularly about the rivers Senegal and Gambia. Theſe cloths are folded ſquare-wiſe, and are about eight ells long.

CANNES, in *Geography*, a ſmall town and harbour of France in the department of the Var, and diſtrict of Graſſe, which gives name to a bay formed by Cape Garaup or Garoupe. N. lat. 43° 34'. E. long. 7° 7'.

CANNESIS, a town of Louiſiana, on the north bank of Red River, a branch of the Miſſiſippi.

CANNETE, a town of Spain, in the province of Cordova; 18 miles E. of Cordova.—Alſo, a town of Spain, in the province of Seville; 5 leagues S. of Oſſuna.

CANNETS, Fr. in *Heraldry*, ducks repreſented without beaks or feet. Cannets have their heads in profile, and they differ from *Allerions*, which are always diſplayed and full-faced, and they have longer and more encircling necks than thoſe of the martlets.

CANNETTE, in *Geography*. See Cagnete.

CANNIA, a place in the iſland of Ceylon, about ſix miles from the fort of Trincomalee on the road to Candy, famous for its ſprings, the waters of which are reckoned very efficacious in rheumatic complaints. The ſprings are ſix in number, and of different degrees of heat; they all communicate with one another, and exhibit the ſame phenomena. Their heat varies from 98° to 106½° of Fahrenheit's thermometer, nearly in proportion to their different depths. From an analyſis of theſe waters it appears that they poſſeſs few mineral qualities, or perhaps any virtue beſides their heat, which is of a temperature not unfavourable for hot bathing. Percival's Ceylon, p. 360.

CANNIBAL, or Canibal, is uſed by modern writers for an *anthropophagus*, or man-eater, more eſpecially of the Weſt Indies. See Anthropophagi.

In the ancient world, tradition has preſerved the memory of barbarous nations of cannibals, who fed on human fleſh, and in every part of the new world there were people to whom this cuſtom was familiar. It prevailed in the ſouthern continent in ſeveral of the iſlands (See Caribbees), and in various diſtricts of North America. Even in ſome parts where the practice has been aboliſhed, it ſeems formerly to have been ſo well known, that it is incorporated into the idiom of their language. Among the Iroquois, the phraſe by which they expreſs their reſolution of making war againſt an enemy is "Let us go and eat that nation." If they ſolicit the aid of a neighbouring tribe, they invite it to eat broth made of the fleſh of their enemies." Nor was this practice peculiar to rude unpoliſhed tribes: the principle from which it took riſe is ſo deeply rooted in the minds of the Americans, that it ſubſiſted in Mexico, one of the civilized empires of the new world, and relics of it may be diſcovered among the more mild inhabitants of Peru. It was not ſcarcity of food, as ſome authors imagine, and the importunate cravings of hunger, which forced the Americans to theſe horrid repaſts on their fellow-creatures. Human fleſh was never uſed as common food in any country. It was the rancour of revenge that firſt prompted men to this barbarous action. The fierceſt tribes ſeldom devoured any but priſoners taken in war, or ſuch as they regarded as enemies.

This fact is confirmed by two remarkable circumſtances, which occurred in the conqueſt of different provinces. In the expedition of Narvaez into Florida, in 1528, the Spaniards were reduced to ſuch extreme diſtreſs by famine, that in order to preſerve their own lives, they ate ſuch of their companions as happened to die; this appeared ſo ſhocking to the natives, who were accuſtomed to devour none but priſoners, that it filled them with horror and indignation againſt the Spaniards. During the ſiege of Mexico alſo, though the Mexicans devoured with greedineſs the Spaniards and Tlaſcalans, whom they took priſoners, the utmoſt rigour of the famine which they ſuffered could not induce them to touch the dead bodies of their own countrymen. The authorities for theſe facts are cited in Dr. Robertſon's Hiſt. of America, vol. ii. p. 501. See Anthropophagi. See alſo the articles America, Ansiko, Batta, Surinam, and New Zealand.

CANNOCK, or Cannot-*ſtone*, a baſe ſort of iron-ore, in the Staffordſhire mines, of which the worſt metal is made.

CANNON, in French *canon*, from the Italian word *cannone*, which is derivable from the Greek word κανὼν, ſignifying the beam of a ſteelyard or balance, a reed, cane, rod, or ruler, &c.; or from κάννα, in Latin *canna*, a cane, reed, ſugar-cane, pipe, &c. This word, in its general acceptation, is applied not only to large guns, howitzers, mortars, carronades, &c. and all heavy pieces of ordnance or artillery, but alſo to the barrels of all ſmaller ſized fire-arms, ſuch as muſkets, carabines, fuſees, piſtols, &c. whether the bores of the ſame be ſmooth on the inſide or rifled. In its more reſtricted and ordinary acceptation, however, it is made uſe of to expreſs a large-ſized fire-arm, a piece of ordnance or artillery, a warlike engine, machine, or inſtrument for projecting or throwing balls, bullets, ſhells, grape-ſhot, ſtones, &c. &c. by means of gunpowder. It has a cylindrical bore or tube running lengthwiſe in the middle of it from the muzzle towards the breech for receiving the charges of powder, ſhot, ſhells, &c. After gunpowder began to be applied to military purpoſes, it ſupplanted and ſucceeded the *tormenta bellica*, or warlike machines of the ancients. The firſt cannons were called *bombardæ*, from βομβος or "a bombo et ardore," on account of the great noiſe, which the firing of them occaſioned; and as they ſucceeded to theſe machines, they were employed like them for throwing large ſtones, and had prodigious calibers. Their forms, as well as the engines and inſtruments made uſe of for managing, moving, and conducting them, were only ſuch as the moſt obvious incidents ſuggeſted, or the rudeſt and moſt uncultivated invention dictated. They uſually conſiſted of bars or pieces of iron fitted, and ſometimes ſoldered together lengthwiſe, and hooped with iron rings. Being long beyond all juſt or due proportion; they were heavy, clumſy, and in a great degree unmanageable; and as they were uſed for throwing ſtones, like the machines they ſucceeded, they were neceſſarily of a huge or enormous bore, and could not be fired but at great intervals of time. Such were thoſe with which we are told Mahomet II. battered the walls of Conſtantinople in the year 1453, being ſome of them of the caliber of no leſs than 1200 pounds. Though ſome uſe had been made of guns in Europe upwards of a century before, ſo little improvement had been made in their conſtruction that they could not be fired above three or four times a day or diſcharged often without burſting. And Guicciardin, in the firſt book of his hiſtory, informs us, that ſo great a portion of time intervened between the different chargings and diſchargings of one of thoſe ponderous and unwieldy pieces, that the beſieged had ſufficient time to repair at their leiſure the breaches made in their walls by the ſhock of the huge and enormous ſtones, that were thrown from them. For a conſiderable time, indeed, after men began to apply gunpowder to military purpoſes, their guns were very long, heavy, and unmanageable, and of courſe very unfit for quick or expeditious ſervice. Military people at that time poſſeſſed but a ſmall ſhare of learning of any kind, and almoſt none at all of a mechanical or mathematical nature. What they did profeſſionally in regard to the management of artillery was entirely the effect of practice and a bare repetition of what they ſaw every day done.

But as mathematical knowledge increaſed in Europe, that of mechanics gradually advanced, and enabled artiſts by making both braſs and iron cannon of a much ſmaller bore for receiving iron bullets, and a much greater charge of ſtrong powder in proportion to their calibers, to produce a very material and important change in the conſtruction and fabric of thoſe original pieces. Accordingly this hiſtorian, in the ſame book of his hiſtory, informs us, that about 114 years after the firſt uſe made of thoſe ponderous and unwieldy pieces by the Venetians, in the war which they carried on againſt the Genoeſe in the year 1380, the French were able to procure for the invaſion of Italy a great number of braſs cannon, mounted on carriages, drawn by horſes inſtead of oxen; and that theſe pieces could always keep pace with the army.

In enumerating the advantages, which aroſe from this alteration in the ſtructure and management of artillery, he obſerves, that the pieces were pointed with incredible quickneſs and expedition in compariſon of thoſe formerly made uſe of in Italy, were fired at very ſmall intervals of time, and could produce in a few hours an effect, which thoſe others could not have produced in the ſpace of many days. In ſpeaking of theſe matters he uſes the following words.

"Et per unerſi con queſto eſercito erano ſtate condotte per mare a Genoua quantità grande d'artiglierie da battere le muraglie et da uſare in campagna, ma di tal ſorte, giammai non havava veduta Italia le ſemighanti. Queſta peſte trovata molt' anni innanzi in Germania fu condotta la prima volta in Italia da Venetiani nella guerra, che circa l'anno della ſalute 1380 hebbono i Genoueſi con loro—Il nome delle maggiori era bombarde, le quali, ſparſa dopo queſta inventione per tutta Italia s'adoperavano nell' oppugnationi delle terre, alcune di ferro, alcune di bronzo ma groſſiſſime, in modo che per la machina grande et per l'imperitia de gli huomini et mala attitudine de gl' inſtrumenti tardiſſimamente et con grandiſſima difficulta ſi conducevano, piantavanſi alle terre co' medeſimi impedimenti et piantate era dall' un colpo all' altro tanto intervallo, che con peccoliſſimo frutto, a comparatione di quello, che ſegnito dopo molto tempo conſumavano, donde i defenſori de luoghi oppugnati havevano ſpatio di potere otioſamente fare di dentro ripari et fortificationi. Ma i Franceſi fabricando pezzi molto più eſpediti, nè d'altro che di bronzo, i quali chiamavano cannoni, et uſando palle di ferro, dove prima di pietra et ſenza comparatione piu groſſe et di peſo graviſſimo s'uſavano li conducevano in ſulle cerette tirate (non da buoi come in Italia ſi coſtumava) ma da cavalli con agilita tale d'huomini et d'inſtrumento deputati a quello ſervigio, che quaſi ſempre al pari de gli eſerciti caminavano, et condotte alle muraglie erano piantate con preſtezza incredibile, et interponendoſi dall' un colpo all' altro piccoliſſimo intervallo di tempo ſi ſpeſſo et con impeto ſi gaghardo percuotevano, che quello che prima in Italia fare in molti giorni ſi ſoleva do loro in pochiſſime hore ſi faceva."

Theſe pieces uſed generally to throw iron-balls from forty to ſixty pounds in weight; and this change in the formation of artillery has not as yet undergone many material alterations. Lighter guns indeed are now employed than thoſe, that were made uſe of at firſt; but they have ſuffered greater variations in reſpect of ſize than proportion.

When, or by whom, guns were firſt invented is uncertain, ſince the origin both of them and of gun-powder is involved in obſcurity; though it is highly probable, that mixtures or compoſitions ſimilar to that of gun-powder were made ſoon after the diſcovery of ſalt-petre, becauſe it is difficult to conceive how the one diſcovery could exiſt long without the other.

The great increaſe of inflammability, which ſalt-petre gives to igneous or inflammable ſubſtances, when mixed with them, muſt ſoon after it was diſcovered itſelf have led to ſuch a mixture. For a ſmall part of it being either thrown or falling accidentally into any fire muſt have manifeſted this diſtinguiſhing quality in it and its prodigiouſly exploſive power when mixed with burning bodies, and have led to the idea of rendering inflammable materials violently and exceſſively more ſo than they are naturally, and powerfully exploſive, by mixing them with ſalt-petre. If the time could, therefore, be aſcertained when this ſubſtance firſt came to be made uſe of, conjectures might with ſome ſort of certainty, or at leaſt probability, be formed when mixtures like the compoſition of gunpowder were firſt made or invented. Such a diſcovery or invention, however, might long exiſt before a convenient and advantageous method of applying it to military projectiles might be thought of or ſuggeſted.

An opinion has generally prevailed, that ſalt-petre was firſt diſcovered either by the Arabians or the later Greeks, about the middle ages of the chriſtian æra, when alchemy and chemiſtry were much attended to and cultivated by both nations. It is even ſaid that the Arabic name for it is expreſſive of its exploſive quality. And if the Greek fire made uſe of by the later Greek emperors poſſeſſed this exploſive property, and produced the effects attributed to it, there muſt have been ſome ſalt-petre in its compoſition.

Whether ſalt-petre was known to the ancients, ſeems to be a matter of conſiderable uncertainty. They had, however, both in Europe and Aſia, their fiery tubes or cannæ, which, being loaded with ſtones, pitch, and iron balls, were exploded with a violent noiſe, much ſmoke, and great effect. And there are ſeveral paſſages, both in the Greek and Roman writers, which ſhew, that the Greek fire itſelf was uſed by both nations in their wars, and afford reaſons for tracing it back to a much earlier date than 660, or the ſea fight in the Helleſpont, commanded by Conſtantine Pogonates againſt the Saracens, and aſcribing the invention of it to Marcus Gracchus or Græcus.

The invention of gunpowder is uſually, though erroneouſly, aſcribed to one Bartholdus Schwartz, who is ſaid to have diſcovered it about the year 1320; and the Venetians are commonly ſuppoſed to have made the firſt application of it to military purpoſes in their war againſt the Genoeſe about the year 1380. Both of theſe ſuppoſitions, however, are certainly without foundation. For Roger Bacon, who lived almoſt fifty years before Schwartz, deſcribes a compoſition perfectly reſembling that of gunpowder; and unqueſtionable proofs can be produced of the uſe of artillery much earlier than the year 1380, even in Europe.

Bacon does not mention this compoſition as a new one, but ſpeaks of it as in common uſe for recreative fire-works, and only propoſes to apply a well known one to the deſtruction of armies by the violent effects of its flame unconfined. This is the firſt well-authenticated hint, that was given in Europe of the application of gunpowder to warlike purpoſes; though the Germans attempt to trace back the invention of cannon as far as 1250, and aſcribe it to Albertus Magnus, a Dominican monk.

That gunpowder, however, was both known and made uſe of long before the time, either of Roger Bacon, or Albertus Magnus, is a fact that cannot be denied. This is eſtabliſhed beyond even the poſſibility of diſpute by the treatiſe of Marcus Græcus, entitled "Liber ignium," which is in manuſcript in the Royal library at Paris. Doctor Mead had this treatiſe alſo in manuſcript, a copy of which is now in the poſſeſſion of the ingenious and learned Dr. Hutton. The author of it deſcribes ſeveral ways of encountering and oppoſing an enemy by launching fire on him, and among other things, gives the following directions. Mix together one pound of live ſulphur, two of charcoal of willow, and ſix of ſalt-petre, reducing them to a very fine powder in a marble mortar; then put a certain quantity of this mixture into a long, narrow and well compacted cover, and then diſcharge it into the air. This is exactly the deſcription of a rocket. He repreſents the cover, with which thunder is imitated as ſhort, thick, but half-filled, and ſtrongly bound with packthread, which is exactly the form of a cracker. He then delivers different methods for preparing the match, and explains how one ſquib may ſet fire to another in the air by having it incloſed within it. He deſcribes two kinds of fire-works, one for flying, and the other for making a loud report. He directs the caſe, *tunica*, or cartouche for the firſt to be made long and ſlender, and the compoſition to be very cloſely rammed; and the caſe for the ſecond to be thick and ſhort, and only about half filled. His compoſition for both is ſtronger than a great deal of gunpowder that is made now. It muſt, indeed, be acknowledged, that he treats as expreſly and diſtinctly of gunpowder and the effect of it, as any perſon writing on the ſubject, even at preſent poſſibly could do. He does not, however, ſpeak of ſuch compoſitions as uſed in war, which ſhews at leaſt, that they were known before the uſe of any ſort of fire-arms in thoſe parts of the world, he was acquainted with. And as he does not pretend to be the inventor of theſe rockets and crackers, or mention them as things new or recent, it may reaſonably be preſumed, that they were in uſe long before his time, which is not aſcertained to a certainty, though he muſt have lived as early at leaſt as the eighth century. We have reaſon alſo to conclude from the authorities of many authors, and a variety of concurrent and corroborating circumſtances, that gunpowder or compoſitions reſembling it, were known to the Chineſe and Indian nations, even thouſands of years ago. And it is alſo aſſerted by many modern travellers, that guns were made uſe of in China as far back as the year of Chriſt, 85, and that they have continued to be uſed there ever ſince. This aſſertion receives additional force and authority from the prohibition of fire-arms in the code of Gentoo laws, printed by the Eaſt India company in 1776. But there is reaſon to ſuppoſe that their fire-arms always were and have ever been in a very rude, imperfect, and inconvenient ſtate compared to thoſe that have been and are now uſed in Europe.

Though Bartholdus Schwartz has no claim whatever to the invention of gunpowder; it is alleged, and with great probability, that the ſimpleſt and moſt convenient method of applying it to military purpoſes in Europe, was firſt ſuggeſted to him, in 1320, by a ſpark of fire falling accidentally on a mixture of pounded nitre, ſulphur, and charcoal, in a mortar imperfectly covered with a ſtone, which was thrown by the exploſion to a conſiderable diſtance. The very figure and name of mortars given to a ſpecies of artillery, which are ſaid to have been made uſe of even before guns properly ſo called, and were employed at firſt for throwing large ſtones at conſiderable angles of elevation, render this conjecture probable.

Guns were ſoon after that incident employed in war. But mortars and great guns were firſt made uſe of.

Father Daniel in his life of Philip, of Valois, produces a proof from the records of the chamber of accounts at Paris, that cannon were uſed in the year 1338. And Du Cange finds mention made of them in Froiſſart, and other French hiſtorians ſome time earlier. In the liſt of aids raiſed for the redemption of John king of France, in 1368, mention is made of an officer in the French army under the denomination or appellation *of maſter of the king's cannon*, and of his providing four large cannons for the garriſon of Harfleur. There was one in the arſenal of Bamberg as early as 1323. The French uſed them in 1338, for the attack of ſome caſtles. But they did not certainly employ them in the field againſt their fellow creatures near ſo early as the Engliſh, who under Edward III., placed five of them, in 1346, on a ſmall hill near the village of Creſſy, which chiefly contributed to decide the celebrated battle of that name. From this circumſtance ſeveral of the French writers have laid claim to a greater degree of national humanity than they allow to the Engliſh. One of them, treating of cannon, expreſſes his ſentiments on the ſubject in the following words. "On ne faiſoit point encore uſage en France, en 1547, de cette arme terrible contre les hommes; les Francais s'en etoient bien ſervi, in 1338, pour l'attaque de quelques chateaux, mais ils rougiſſoient de l'employer contre leurs ſemblables. Les Anglais moins humains ſans doute nous devancerent et s'en ſervirent a la célèbre bataille de Creci, qui eut lieu entre les troupes du roi d'Angleterre Edouard III. qui fut ſi mechant, ſi perfide, qui donna tant de fil a retordre a Philippe de Valois, et aux troupes de ce dernier; et ce fut en majeure partie à la frayeur et à la confuſion, qu' occaſionnerent les canons dont les Anglais ſe ſervoient pour la premiere fois, et qu'ils avoient poſtés ſur une colline, proche le village de Creci, que les Français durent leur déroute." The Engliſh alſo made uſe of them the year following, viz. in 1347, at the ſiege of Calais.

It is generally believed that cannon have been made uſe of in Europe ever ſince the year 1338, and that they were employed for naval purpoſes on the Baltic ſea, in 1350. At any rate, it is certain that they were uſed by the Venetians, in 1366, at the ſiege of Claudia Jeſſa, now called Chioggia, and in their war with the Genoeſe in 1379 and 1380. Six years after this laſt-mentioned period the Engliſh carried cannon into England in two French veſſels, which they had captured.

Larrey aſcribes the invention of braſs cannon to J. Owen. He aſſerts that there were none ſuch known in England till the year 1535, and that iron-cannon were for the firſt time caſt in it in 1547. The Engliſh, however, did not manufacture many of theſe till towards the end of the 16th century.

Specimens of great guns, as they were firſt uſed, and before the caſting of them in founderies came into practice, are ſtill to be ſeen in many parts of Europe, and ſome of them in the tower, and the warren at Woolwich. Such an inſtrument or engine of war was firſt called *bombarde*, afterwards *cannon*, and now commonly goes by the name of a piece of ordnance or artillery. The word cannon, however, is ſtill applied to that part of every fire-arm great or ſmall, that receives the powder.

Cannon were formerly made of a very great length, which rendered them exceedingly heavy, and the uſe of them very limited and troubleſome. There were ſome of them employed by the Turks, in 1394, at the ſiege of Conſtantinople then in poſſeſſion of the Chriſtians, and alſo in 1452, which threw a weight of 100 lib.; but they could not ſtand repeated firing. Louis XII. had one caſt at Tours of the ſame ſize, that threw a ball from the Baſtile to Charenton. One of theſe extraordinary cannon was taken at the ſiege of Dien, in 1546, by Don John de Caſtro, and is now in the caſtle of St. Julian de Barra ten miles from Liſbon. The length of it is twenty feet ſeven inches; its diameter at the middle is ſix feet three inches; and it threw 100 lib. weight. It has neither dolphins, rings, nor a button; is of an unuſual kind of metal, and has a large Indoſtan inſcription on it, which ſays that it was caſt in 1400.

Formerly ſtrange and uncommon names were given to cannon. Thus Louis XII., in 1503, had twelve braſs cannon caſt of an extraordinary ſize called after the twelve peers of France. The Spaniards and Portugueſe named theirs after their ſaints. The emperor Charles V., when he went againſt Tunis, had twelve cannon founded, which he called the Twelve Apoſtles. At Milan there is a ſeventy pounder called the Pimontelli; and there is one at Bois-le-duc called the Devil. At Dover caſtle there is a ſixty pounder called Queen Elizabeth's pocket-piſtol. There is an eighty pounder in the tower of London brought thither from Edinburgh caſtle called Mounts-meg. There is alſo an eighty pounder in the royal arſenal at Berlin called the Thunderer, and one of the ſame caliber at Malaga called the Terrible. There are two curious ſixty pounders in the arſenal at Bremen called the Meſſengers of bad news. And laſtly there is an uncommon ſeventy pounder in the caſtle of St. Angelo at Rome, made of the nails that faſtened the copper plates which covered the ancient Pantheon, with this inſcription on it. "Ex clavis trabalibus porticus Agrippæ."

About the beginning of the 15th century, theſe uncommon names were moſtly laid aſide, and the following among other more general ones adopted.

| | | Pounders. | | Cwt. |
|---|---|---|---|---|
| Cannon royal or carthoun, | | 48 | about | 90 |
| Baſtard cannon or ¾ carthoun, | | 36 | | 70 |
| ½ carthoun, | | 24 | | 60 |
| Whole culverins, | | 18 | | 50 |
| Demi-culverins, | | 9 | | 30 |
| Falcon, | | 6 | | 25 |
| Saker | largeſt ſize, | 8 | | 18 |
| | ordinary, | 6 | | 15 |
| | loweſt ſort, | 5 | | 13 |

| | Pounders. | | Cwt. |
|---|---|---|---|
| Baſiliſk, - - - - - | 48 | about | [illegible] |
| Serpentine, - - - - - | 4 | - - | 8 |

| Le Sacri, | 5 | 2850 | 13 | 0 |
| Le Sacret, | 4 | 2500 | 12 | 0 |
| Le Faucon, | 3 | 2300 | 8 | 0 |
| Le Fauconneau, | 2 | 1350 | 10 | 6 |
| Le Ribadequin, | 1 | 700 | 8 | 0 |
| Un autre Ribadequin, | ½ | 450 | 6 | 0 |
| L'Emerillon, | ¼ | 400 to 450 | 4to5 | |

At preſent cannon take their names from the weights of the balls, which they reſpectively diſcharge. Thus a piece that diſcharges a ball of 24 pounds, is called a 24 pounder; one that takes a ball of 12 pounds, is called a 12 pounder; and ſo of the reſt divided into the following ſorts.

Ship-guns, conſiſting of 42, 36, 24, 18, 12, 9, 6, and 3 pounders.

Garriſon guns, conſiſting of 42, 32, 24, 18, 12, 9, and 6 pounders.

Battering guns, conſiſting of 24, 18, and 12 pounders, and ſometimes though but ſeldom of 42 pounders.

Field pieces conſiſting of 12, 9, 6, 3, 2, 1½, 1, and ½ pounders.

Table of ſhip-guns ſettled in 1753.

| | 9 | 7 | 0 | 23 | 0 | 0 | 4.21 | 4.00 |
| | 6 | 9 | 0 | 24 | 0 | 0 | 3.66 | 3.48 |
| | 6 | 8 | 6 | 23 | 0 | 0 | 3.66 | 3.48 |
| | 6 | 8 | 0 | 22 | 0 | 0 | 3.66 | 3.48 |
| | 6 | 7 | 6 | 20 | 2 | 0 | 3.66 | 3.48 |
| | 6 | 7 | 0 | 19 | 0 | 0 | 3.66 | 3.48 |
| | 6 | 6 | 6 | 18 | 0 | 0 | 3.66 | 3.48 |
| | 6 | 6 | 0 | 16 | 2 | 0 | 3.66 | 3.48 |
| | 4 | 6 | 0 | 12 | 1 | 0 | 3.21 | 3.04 |
| | 4 | 5 | 6 | 11 | 1 | 0 | 3.21 | 3.04 |
| | 3 | 4 | 6 | 7 | 1 | 0 | 2.91 | 2.77 |
| | ½ | 3 | 0 | 1 | 1 | 25 | 1.58 | 1.52 |

The following are the dimenſions, &c. eſtabliſhed by the Board of Ordnance in 1764 for braſs howitzers, which may be regarded as a ſort of ſhort cannon, mounted like guns on travelling carriages, and were much later in coming into uſe than either guns or mortars.

### Brass Howitzers.

| Nature. | Length. | | Weight. | | | Caliber of the howitzer. | Diameter of the ſhell. | Chamber contains powder. | |
|---|---|---|---|---|---|---|---|---|---|
| inches | ft. | in. | cwt. | qr. | lib | in. hund. | in. hund. | lib. | oz. |
| 8 | 3 | 1 | 11 | 0 | 0 | 8. 0 | 7.75 | 3 | 8 |
| 5 8 | 2 | 2 | 4 | 0 | 14 | 5.62 | 5.50 | 1 | 0 |
| 4.5 | 1 | 10 | 2 | 0 | 14 | 4.52 | 4.40 | 0 | 8 |

Mortars are alſo a kind of ſhort cannon of large bores, with chambers, and are made either of braſs or iron. The following are the dimenſions, &c. of all kinds of braſs mortars, whether for land or ſea ſervice, as eſtabliſhed by the Board of Ordnance in 1764.

### Brass Mortars.

| Natures. | Length. | | Weight. | | | Caliber of the mortar. | Diameter of the ſhell. | Chamber contains powder. | |
|---|---|---|---|---|---|---|---|---|---|
| inches | ft. | in. | cwt. | qr. | lib. | in. hund. | in. hund. | lib. | oz. |
| 13 Sea | 5 | 3 | 82 | 0 | 0 | 13.0 | 12.75 | 30 | 0 |
| 10 Sea | 4 | 9 | 33 | 0 | 0 | 10.0 | 9.75 | 12 | 8 |
| 13 Land | 3 | 8 | 25 | 0 | 0 | 13.0 | 12.75 | 10 | 0 |
| 10 Land | 2 | 9 | 11 | 0 | 0 | 10.0 | 9.75 | 3 | 12 |
| 8 Land | 2 | 2 | 4 | 0 | 0 | 8.0 | 7.75 | 2 | 0 |
| 5, 8 or royal. | 1 | 4 | 1 | 1 | 0 | 5.62 | 5.50 | 0 | 9 |
| 4, 5 or coehorn | 1 | 1½ | 0 | 3 | 0 | 4.52 | 4.40 | 0 | 5 |

The following table ſhews, at one view, the lengths and weights of our braſs cannon as they ſtand at preſent, with their reſpective calibers, or the diameters of their bores, the diameters of their ſhot, and of their ſhot gauges, the quantities of powder employed for proving them reſpectively, their reſpective charges for ſervice, for ſaluting with them, and for ſcaling them.

### BRASS GUNS OR CANNON.

| Nature. | Length. | | Weight. | | | Quantity of Powder uſed for | | | | | | | | Calibers or Diameters of the Bores. | Diameters of the Shot. | Diameters of the Shot Gauges. | Number of Calibers in the length of each. | Number of Diameters of the Shot in the length of each. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

The names of the ſeveral parts of a cannon are the following. See *Plate* I. *Cannon*, *fig*. 1.

A B is the whole length of the gun, which is reckoned from the hind part of the baſe ring, or the beginning of the caſcable, to the extremity of the muzzle or mouth of the piece: and the grand exterior diviſions are theſe that follow.

A E. The firſt reinforce, or that part of the gun which is next to the breech, and is made ſtronger than the other parts to reſiſt the force of the powder. It includes the baſe ring, the ogee next to it, the vent-field, the vent-aſtragal, and the firſt reinforce-ring. E F. The ſecond reinforce. It begins where the firſt reinforce ends, and is made ſomewhat ſmaller than the firſt. It includes the ogee next to the firſt reinforce ring, the trunnions, and the ſecond reinforce ring. F B. The chace, beginning where the ſecond reinforce ends, and extending from thence quite to the muzzle. It includes the ogee next to the ſecond reinforce ring, the chace-girdle and aſtragal, and the muzzle and aſtragal. H B. The muzzle, properly ſo called, reaches from the beginning of the muzzle aſtragal to the mouth of the piece. But the word muzzle is alſo ſometimes made uſe of to expreſs the mouth of the gun.

The ſmaller exterior diviſions of a cannon are the following:

A*h*. The caſcable, the hindermoſt part of the breech of the gun, extending from the baſe ring to the extremity of the knob or button. *b*. The caſcable-aſtragal, which is the part that diminiſhes between the two breech-mouldings. *c*. The neck of the caſcable, which is the narrow, rounding, diminiſhing part of the metal between the breech-moulding and the button. A C. The breech. The ſolid piece of metal or part of the gun from the vent to the extremity of the baſe-ring, terminating where the caſcable begins. A *i*. The breech-mouldings. They are thoſe eminent or prominent rounding parts between the baſe ring and the neck of the caſcable, and ſerve only as ornaments to the piece. *r s*. The baſe-ring and ogee, or reſiſtance. Theſe are ornamental mouldings, the latter of which is always ſomewhat in the ſhape of S. is taken from civil architecture, and made uſe of in guns, mortars, and howitzers. C D. The vent-field. It is the part that extends from the vent to the firſt reinforce-aſtragal. *t*. The vent-aſtragal and fillets, or the mouldings and fillets at or near the vent. *u*. The charging cylinder, which is all the ſpace or length from the chace aſtragal to the muzzle-aſtragal. *p q*. The firſt reinforce-ring and ogee, which is the ornament on the ſecond reinforce. *f*. The firſt reinforce-aſtragal, which is the ornament between the firſt and ſecond reinforce. F I. The chace-girdle, which is the ornament cloſe to the trunnions. T. The trunnions, which are two ſolid cylindrical pieces of metal, in every gun, which project from the ſame, and ſupport it on its carriage. G. The dolphins, which are two handles placed on the ſecond reinforce-ring of braſs guns, which reſemble the fiſh of that name. They are uſeful for mounting and diſmounting the guns with. V W. The ſecond reinforce ring and ogee are the two ornaments joining the trunnions. V. The ſecond reinforce-aſtragal, which is the moulding neareſt the trunnions. X. The chace-aſtragal and fillets are the two laſt mentioned ornaments taken jointly. Z. The muzzle-aſtragal and fillets are the joint ornaments neareſt to the muzzle. *m*. The ſwelling of the muzzle or projecting part behind the muzzle mouldings. *n*. The muzzle-mouldings, which are the ornaments at the very muzzle or mouth of the piece.

The interior parts of a cannon are the following:

*o*. The bore, is the interior cavity which receives the powder and ſhot. *a*. The mouth, is the entrance of the bore. *d*. The vent, which in all kinds of fire-arms is commonly or vulgarly called the touch-hole. It is a ſmall hole, pierced at or near the end of the bore or chamber for priming the piece with powder, or for introducing the tube, in order, when lighted, to ſet fire to the charge. *e*. The chamber, which is uſed only in guns of large calibers, is the place where the powder forming the charge is lodged.

The following are tools for loading and firing cannon.

Coins, or wedges, which are laid under the breech of a gun, for the purpoſe of either elevating or depreſſing it.

Handſpikes, for moving and laying it with.

Ladles, for loading the gun with looſe powder.

Rammers, which are cylinders of wood, of the ſame diameters and axes with the ſhot. They ſerve for ramming home the wads put upon the powder and ſhot.

The ſponge, which is fixed at the oppoſite end of the rammer, covered with lambſkin. It ſerves for cleaning out the gun when fired.

Screws, which are uſed with field-pieces, inſtead of coins or wedges. The ſcrew ſerves not only for elevating or depreſſing the gun, but for keeping it at the ſame angle of elevation or depreſſion.

The tools neceſſary for proving cannon are the ſearcher with a reliever, and the ſearcher with one point.

The ſearcher is an iron, hollow at one end to receive a wooden handle, and on the other end has from four to eight flat ſprings, of about eight or ten inches long pointed and turned outwards at the ends.

The reliever is an iron flat ring, with a wooden handle at right angles to it. When a gun is to be ſearched, after it has been fired, this ſearcher is introduced, and turned every way from end to end; and if there is any hole the point of one or other of the ſprings gets into it, and remains till the reliever, paſſing round the handle of the ſearcher, and preſſing the ſprings together, relieves it.

When there is any hole or roughneſs in the gun, the diſtance from the mouth is marked on the outſide with chalk.

The other ſearcher has alſo a wooden handle, and a point at the fore end, of about an inch long, at right angles to the length. About this point is put ſome wax mixed with tallow, which when introduced into the hole or cavity is preſſed in, when the impreſſion on the wax gives the depth; and the length is known by the motion of the ſearcher backwards and forwards. If a hole is one-ninth of an inch deep, the gun is rejected.

Cannon, *Conſtruction of.* Moſt nations in a great meaſure agree in the form and general diviſions of a cannon, with the exception that the French place the trunnions half a caliber farther back, or nearer to the breech than others.

As the lengths fixed on by general Armſtrong, formerly ſurveyor general of the ordnance, as beſt for ſome guns, in conſequence of experiments made by him, are ſtill retained by us, it may not be improper to give his general conſtruction both for braſs and iron cannon, which is as follows.

The whole length of the gun being divided into ſeven equal parts, take the length of the firſt reinforce, A E, equal to two of theſe parts, and that of the ſecond reinforce, E F, equal to one of theſe parts, together with one diameter of the bore, leaving the length of the chace equal to four of theſe parts, wanting one diameter of the bore.

The thickneſs of the breech, A C, or the diſtance from the hind part of the baſe ring to the beginning of the bore, is always equal to the thickneſs of the metal at the vent. The trunnions, T, are always one caliber or diameter of the bore in length clear of the ſecond reinforce ring, and as much in diameter; and they are placed in ſuch a manner, that a right line drawn through their centres touches the lower part of the bore, as in *fig.* 4. where that line is marked *a b*. The length of the caſcable, A *h*, is always equal to two calibers or diameters of the bore and a quarter.

The following are the general dimenſions of braſs guns, according to this conſtruction.

Suppoſing the caliber of the gun to be divided into 16 equal parts,

| | Inches. |
|---|---|
| The thickneſs of the metal, from the hind part of the baſe ring to the bore, or thickneſs of the breech will be | 16 |
| The thickneſs of the metal at the end of the firſt reinforce ring will be | 14.5 |
| Thickneſs of the metal at the ſame place, or at the beginning of the ſecond reinforce | 13.5 |
| Thickneſs of the metal at the end of the ſecond reinforce | 12.5 |
| Thickneſs of do. at the ſame place, or the beginning of the chace | 11.5 |
| Thickneſs of do. at the end of the chace or muzzle, excluſive of the mouldings | 8 |

*Mouldings.*

| | |
|---|---|
| Breadth of the baſe ring | 1.5 |
| Breadth of the ogee next to the baſe ring | 2.0 |
| Diſtance from the ogee to the fore part of the aſtragal one calibre | |
| Breadth of each of the fillets of the aſtragal | 0.28 |
| Breadth of the aſtragal, or half round | 0.56 |
| Total breadth of the aſtragal and fillets | 1.12 |
| Breadth of each of the fillets at the firſt and ſecond reinforce ring | 0.25 |
| Breadth of the firſt and of the ſecond reinforce rings | 1.25 |
| Breadth of the ogees, next to theſe rings | 1.5 |
| Breadth of the fillets at the muzzle | 0.25 |

The muzzle ogee in a 12 pounder, and guns of higher calibers is equal to 1.25 inches or 1¼ inch. But in a 9 pounder, and guns of ſmaller calibers, it is only equal to one inch. The chace-girdle and aſtragal are equal to one caliber.

The diſtance from the mouth of the gun to the muzzle aſtragal is equal to a diameter of the ſecond reinforce ring, in 18 pounders and guns of higher calibers; but in a 12 pounder, and guns of ſmaller calibers, it is equal to the diameter of the firſt reinforce-ring.

The riſing or ſwelling of the mouldings at the firſt and ſecond reinforces is about an eighth part of an inch; and the riſing of the baſe-ring is determined by laying a ruler to the extremities of the firſt and ſecond reinforce mouldings.

The diameter of the gun, through the ſwelling of the metal at the muzzle, is always equal to the diameter of the ſecond reinforce ring.

*Parts of the Caſcable.*

From the hind part of the baſe ring to the fore part of the fillet next to the button, the diſtance is equal to three-fourth parts of a caliber. The diſtance from the fore part of the fillet next to the button to the centre of the button is equal to one caliber. The diſtance from the hind part of the baſe ring to the hind part of the fillet, between the two ogees, is a ſixth part of the caliber. The diameter of the fillet next to the button is equal to one caliber and a half. The diameter of the neck of the caſcable is equal to three fourth parts of a caliber. The diameter of the button is ſomewhat more than one caliber.

It is proper to obſerve, that the ſhell at the vent is three inches broad, and reaches from the baſe ring to within a quarter of an inch of the vent-aſtragal, leaving that ſpace for the eaſe of turning. And the vent is the fifth part of an inch.

General dimenſion, according to this conſtruction, for iron guns.

Suppoſing the calibre of the gun to be divided into 14 equal parts, we ſhall have,

| | Parts. |
|---|---|
| The thickneſs of the metal at the vent from the bore | 16 |
| The thickneſs of do. at the end of the firſt reinforce, equal to | 14.5 |
| The thickneſs of do. at the beginning of the ſecond reinforce equal to | 13.5 |
| The thickneſs of do. at the end of the ſecond reinforce equal to | 12.5 |
| The thickneſs of do. at the beginning of the chace equal to | 11.5 |
| The thickneſs of do. at the end of the chace or muzzle, equal to | 8 |

The mouldings, and the reſt of the dimenſions, are nearly the ſame as in the braſs guns. The diameter of the vent, however, in his iron guns, is one-fourth part of an inch, whereas it is only a fifth part of an inch in his braſs cannon.

The length of braſs guns, according to him (general Armſtrong), are the following:

The

| | ft. | in. |
|---|---|---|
| The 32 pounder | 10 | 0 |
| The 24 pounder | 9 | 5 |
| The 18 pounder | 9 | 5 |
| The 12 pounder | 9 | 0 |
| The 6 pounder | 8 | 0 |
| The 3 pounder | 7 | 0 |
| The 1½ pounder | 6 | 0 |

And, according to him, the length of the iron

| | ft. | in. |
|---|---|---|
| 32 pounder was | 9 | 6 |
| Of the 24 pounder - | 9 | 0 |
| Of the 18 pounder - | 9 | 0 |
| Of the 12 pounder - | 8 | 0 |
| Of the 9 pounder - | 7 | 0 |
| Of the 6 pounder - | 6 | 6 |
| And of the 3 pounder - | 4 | 6 |

General Armſtrong, in order to aſcertain the fitteſt and beſt lengths for battering pieces, made experiments in 1736 with braſs 24 pounders of different lengths, but of nearly the ſame weight. After a great number of trials and experiments with them, he fixed on nine feet ſix inches as the beſt length for a 24 pounder battering piece, though ſome of the ranges with one only nine feet long, with the ſame charge of two-thirds of the weight of the ball, and with the ſame elevation, were ſomewhat greater than the greateſt of thoſe with one nine feet ſix inches long.

In the following table are the lengths of the 24 pounders with which he made a multiplicity of experiments, and three of the longeſt ranges of each, loaded with ſixteen pounds of powder.

BRASS 24 POUNDERS.

| Length. | Range in Yards. | Range in Yards. | Range in Yards. |
|---|---|---|---|
| ft. in. | yards | yards | yards |
| 10 6 | 2488 | 2614 | 2406 |
| 10 0 | 2570 | 2532 | 2436 |
| 9 6 | 2633 | 2560 | 2500 |
| 9 0 | 2796 | 2494 | 2563 |
| 8 6 | 2586 | 2490 | 2466 |
| 8 0 | 2438 | 2470 | 2453 |

Now it is obvious that if we even ſuppoſe all theſe pieces to have been bored exactly alike, and their vents to have been placed alſo exactly alike, with regard to the bottoms of their bores, theſe experiments are not calculated for determining preciſely the beſt length of a 24 pounder, either for battering in breach, or for any other ſervice. For theſe ſuppoſitions relative to their reſpective bores and vents being even granted, no other inference can be drawn from them than this, that nine feet ſix inches is about the beſt length for a 24 pounder, that is to be uſed with a charge of 16 pounds of powder. But a charge equal to two-thirds of the whole weight of the ball is prepoſterouſly large for any kind of ſervice whatſoever. It does not follow from them that nine feet ſix inches would have been found the beſt for a 24 pounder, had the charge he made uſe of been one-half, one-third, one-fourth, or even one-fifth part of the weight of the ball, the laſt of which, if the windage be very ſmall, is ſufficient even for battering with.

If a ſpecific charge of powder be fixed on as the fitteſt for a gun of a given caliber for a given ſervice, the beſt way to aſcertain the proper length of ſuch a gun, it appears, would be to have one of that caliber caſt longer than what is neceſſary, and then to cut it ſhorter and ſhorter, by a few inches at a time, firing it always at the ſame elevation with the given charge. But even this experiment would only determine its fitteſt length for that particular ſervice, with the ſaid aſſumed charge of powder. There ought to be guns of very different lengths, even of the ſame caliber, for different kinds of ſervice. For no one length for a gun of a given caliber will render it fitteſt for various ſpecies of ſervice.

Though the velocity increaſes with the length of the gun, yet it increaſes in a much ſmaller ratio, the velocities being in ratios ſomewhat leſs than the ratios of the ſquare roots of the lengths of the bore, and ſomewhat greater than the ratio, of the cube roots of the ſaid lengths, or nearly in middle ratios between the two. And as the range increaſes in a much leſs ratio than the velocity, being nearly as the ſquare root of the ſame, when the gun and elevation are the ſame, or nearly, as the fifth root of the length of the bore, it is evident that the range is very little increaſed by a great increaſe in the length of the bore. The increaſe, indeed, is ſo ſmall, that doubling the length of the gun does not augment the range more than about a ſeventh part.

As the eaſy and expeditious movement and conveyance of artillery from place to place are of the firſt importance on actual ſervice, and tend greatly to expedite and accelerate operations of an army in the field, it is a conſideration of the utmoſt conſequence to have field-pieces as light as poſſible, both by ſhortening the lengths of their bores, and leſſening their thickneſs of metal. A proper diminution of the windage would make the range of a ſhort gun as great as that of one of double the length with the cuſtomary windage.

The following is a table of the reſults of very uſeful experiments made at Mahon in Minorca in 1745 by general Williamſon, and other officers of artillery, with two iron 18 pounders, one of which was 11 feet long, and weighed 51 cwt. 0 qr. 5 lb. and the other 9 feet long, weighing 39 cwt. 1 qr. 3 lb. The object of theſe experiments was partly to determine which of theſe lengths was fitteſt for an 18 pounder, and partly to aſcertain what charge of powder would give the greateſt ranges with them.

| Length. | Number. | Elevation. | Ranges in Yards. | Powder. |
|---|---|---|---|---|
| 11 Feet. | 1 | 6 Degrees. | 1760 | 9 Pounds of Powder. |

It appears from theſe experiments, that when thoſe eighteen pounders were charged with nine pounds of powder, their ranges were generally ſomewhat greater at the ſame elevation than they were when loaded with either more or leſs; and that thoſe of the eighteen pounder, nine feet long, exceeded thoſe of the other, eleven feet long, with the ſame charge of half the weight of the ball.

They have every appearance of having been made with attention and accuracy. But as they were all made with a charge of powder by far too great for any kind of ſervice with an eighteen pounder, no juſt concluſion can be drawn from them with regard to the beſt length for a gun of that caliber. Beſides, as there were only two lengths made uſe of, the only inference any one can be juſtified in deriving from them is this, that nine feet is a better length than eleven feet for an eighteen pounder, when fired with nine pounds of power. They have no tendency whatſoever to determine what length is fitteſt for a cannon of that caliber, when fired with ſix, or four, &c. pounds of powder.

Mr. Muller, however, regarded them as perfectly concluſive on this head, from finding that 4160 yards, the greateſt range of the piece, nine feet long, at an elevation of 45 degrees, with nine pounds of powder, differed only thirty yards from 4190 yards, the greateſt poſſible range of a gun of that caliber, according to an erroneous theory of his, founded on a miſconception of ſir Iſaac Newton's meaning, in the ſecond book of his Principia, and expreſſes himſelf exultingly in the following words. "Thus we have at laſt determined that important queſtion in artillery ſought for ever ſince its invention."

This gentleman, after aſſerting that the greateſt velocity which a leaden bullet of three quarters of an inch diameter can poſſibly have is that which, uniformly continued, would carry it through 395 feet per ſecond, animadverts on Mr. Robins's method of determining the velocities of ſhot in the following words.

"Mr. Robins thinks to prove, in his ſeventh problem, that the velocity of the foregoing leaden bullet is 1668 feet in a ſecond, which is more than four times greater than that above; and, what is more extraordinary, he pretends to have found the ſame velocity by experiments. As he ſeems to build his theory upon ſir Iſaac Newton's principles, had he read the 40th propoſition, book ſecond, of his Principia, he muſt have been convinced of his miſtake."

This is a heavy charge, and were it well founded, would, in a great meaſure, invalidate all that Mr. Robins has advanced, in regard to the determination of the firſt velocities of ſhot, as this is the only example that Mr. Robins calculates in his ſeventh propoſition from his theory of the elaſtic force of the fluid generated by the firing of gunpowder, which he compares, in his ninth propoſition, with the velocity aſcertained by means of his balliſtic pendulum, and finds to be almoſt the ſame. This is the place that Mr. Muller refers to, when he ſpeaks of Mr. Robins as pretending to have found the ſame velocity by experiments. It is, moreover, deſerving of obſervation, that Mr. Robins does not ſpeak of this velocity as the greateſt that can poſſibly be communicated to ſuch a ball. For a much greater one undoubtedly may be ſo communicated. And it cannot with juſtice be alleged that Mr. Robins built this part at leaſt of his theory on ſir Iſaac Newton's principles, as his method of determining the firſt velocities of bullets is entirely his own. The miſtake lies not with Mr. Robins, but with Mr. Muller himſelf, who could not, when he made the animadverſion, have read with proper attention the ſaid 40th propoſition of the ſecond book of the Principia, which relates entirely to the deſcent of bodies in an infinitely compreſſed and perfectly fluid medium; whereas Mr Robins's calculation juſt mentioned refers expreſsly to projectile motion: and that projectile velocity may be much greater than the greateſt velocity, by which a body can deſcend by its comparative weight in ſuch a fluid, is what no perſon, who has conſidered the ſubject with the leaſt attention, will offer to deny. Even Galileo himſelf, who was the firſt that ſtudied with any care the motions of projectiles and the nature of reſiſting mediums, ſeems to have been ſufficiently ſenſible of this truth. For, in his fourth dialogue, after obſerving that the heavieſt bodies would in time, by deſcending in the air, acquire a degree of velocity which could not afterwards be increaſed in the ſame manner as we ſee light bodies ſoon arrive at their greateſt velocity poſſible, he ſays, "This determinate and ultimate velocity may be called the greateſt which ſuch a heavy body can *naturally* obtain in the air. But this velocity I imagine to be much leſs than that which is given to the ſame ball flung by fired powder." And he propoſes to prove this, by firſt firing a muſket loaded with a leaden ball and a proper charge of powder from a hundred yards high or more againſt a ſtone pavement, and then firing the ſame with a like charge againſt a ſtone of the ſame ſort at a few yards diſtance, and examining which of the balls was moſt flatted. Every body now knows that this imagination of his was perfectly juſt.

Sir Iſaac Newton begins the ſaid propoſition in his ſecond book with a rule for determining the greateſt velocity, with which a globe can deſcend in an infinitely compreſſed and completely fluid medium. His words are the following: "Sit A pondus globi in vacuo, B pondus ejus in medio reſiſtente, D diameter globi, F ſpatium, quod ſit at $\frac{4}{3} \times D$ ut denſitas globi ad denſitatem medii, id eſt, ut A ad $A - B$; G tempus quo globus pondere B ſine reſiſtentia cadendo deſcribit ſpatium F; et H velocitas, quam globus hocce caſu ſuo acquirit. Et erit H velocitas maxima, quacum globus pondere ſuo B in medio reſiſtente poteſt deſcendere." This, however, is the very rule, as is found by calculation, that Mr. Muller made uſe of for determining the greateſt poſſible projectile velocity of a bullet of three quarters of an inch diameter, as well as thoſe of larger ones. It is not, therefore, to be wondered at, that he has given a very erroneous table of the greateſt poſſible velocities of ſhot of different diameters, from three pounds up to forty-eight, and of their greateſt ranges.

As twenty-one diameters of an eighteen pounder ſhot are nearly equal to nine feet, and as nine pounds of powder were a charge equal in weight to half that of the ſhot, Mr. Muller concluded that guns of all calibers having their lengths and charges reſpectively proportional to theſe, would give greater ranges than guns of the ſame calibers with any other lengths and charges, greater or leſs, would give, ſuppoſing, without ſufficient reaſon for doing ſo, the greateſt velocities to be always proportional to the diameters of the ſhot.

He accordingly, in his conſtructions for guns, makes both battering and garriſon cannon from eighteen to twenty-one diameters of their ſhot long reſpectively.

He allows, however, that though it is of advantage to know the beſt length and charge for every piece, the lengths of guns muſt depend on the ſervices they are intended for. He obſerves, that ſhip-guns ſhould, for various reaſons, be ſhort and light; that field-pieces, or battalion-guns, ſhould alſo be ſhort and light, in order to be able to advance or retire as faſt as the army; that battering pieces ſhould be long enough to prevent the flame of the powder, when they are repeatedly fired, from damaging much, or deſtroying very ſuddenly the ſides of the embraſures; and that garriſon guns ought to be of the lengths that give the greateſt ranges, to oblige the beſiegers to break ground at the greater diſtance, and to reach ſhipping, &c. from forts near the ſea, or navigable rivers, as far off from them as poſſible.

In his general conſtruction of braſs cannon for the land ſervice, he ſuppoſes the length of the gun to be twenty-one diameters of the ſhot from a twenty-four pounder incluſive, downwards, giving, however, the ſame length to the thirty-two pounder and to the forty-two pounder that he gives to the twenty-four pounder, making thereby the diameter of the firſt of theſe about nineteen diameters of its ſhot, and that of the laſt about ſeventeen diameters of its ſhot and one third.

*The Conſtruction is this.*

Let the length AB of the piece (ſee *fig.* 1.) be twenty-one diameters of its ſhot; and let the diameter of the ſhot be divided into twenty-four equal parts, from which all the reſt of the dimenſions are to be determined. Make the

| | | |
|---|---|---|
| Diameter of the bore equal to | 25 | ſuch parts. |
| The diſtance from A, the hind part of the baſe-ring, to D, the fore part of the vent-aſtragal | 40 | ſuch parts. |
| The thickneſs of the metal at the breech and vent | 18.5 | ſuch parts. |
| The thickneſs of the metal at the mouth | 9 | ſuch parts. |

Then the lines drawn from theſe points will determine the figure of the gun, which will be therefore from A to D cylindrical, and from thence to the mouth conical.

The centre line of the trunnions croſſes the centre line of the bore at right angles, and at the diſtance of three ſevenths of the whole length AB of the gun, from the hind part A of the breech; the diameter of each of them is equal to eighteen ſuch parts, and its length is equal to its diameter, excluſive of the projection of the ſecond reinforce ring. The length EF of the ſecond reinforce is always equal to two-thirds of AE, the length of the firſt reinforce. The breech AC, is equal to ſixteen ſuch parts; and the chace-girdle is equal to fourteen. The muzzle HB is equal to a tenth part of the whole length of the gun, which is here equal to 50.4 ſuch parts.

| | | |
|---|---|---|
| The breadth of the baſe-ring and ogee next to it are each of them equal to | 6 | ſuch parts. |
| The firſt and ſecond reinforce rings, and the ogee next to them, are each of them equal to | 5 | ſuch parts. |
| Each aſtragal and fillets are equal to | 4 | ſuch parts. |
| The cavetto at the mouth is equal to | 2.5 | ſuch parts. |
| And the fillets are each equal to | 1 | of ſuch parts. |

The baſe-ring projects the metal two ſuch parts, the firſt and ſecond reinforce rings, about one ſuch part; the fillets of the aſtragals, the half of one of ſuch parts; and the round of each aſtragal is deſcribed from a centre in the outline of the piece.

There is a circular ſhoulder about each of the trunnions, of which the diameter exceeds that of either of the trunnions by ſix ſuch parts, and projects ſo as to be even with the ſecond reinforce-ring.

As to the caſcable (ſee *fig.* 2.) the diſtance from A, the hind part of the baſe-ring, to C, the centre of the button, is equal to twenty-ſeven ſuch parts; the radius of the button to nine; the breadth of the quarter round to two; the ogee to five, and the fillets each to one. If from C, the centre of the button, right lines be drawn to the extremities E F of the baſe-ring, and points O, O be found in theſe lines equally diſtant from the button and the ſecond fillet, arcs deſcribed from theſe points with that diſtance will determine the neck, whilſt right lines O P parallel to C A, the direction of the axis of the piece, will fix the extremes, or limit the hind part of the ſecond fillet, and C F determines the firſt.

In order to deſcribe the ogee, join the extremities $n$, $q$ of the hind parts of the fillets; through the point $q$, draw the indefinite right line, $q\,p$ L, parallel to O $n$ produced; biſect the right line $n\,q$ in the point $s$, and through the point of biſection $s$ draw a right line making angles with $n\,q$ equal each to the angle $s\,q$ L, and meeting $q$ L and O $n$ produced in the points, $p$, P, reſpectively. Then arcs deſcribed from the points P, $p$, as centres, with a radius equal to P $n$, P $s$, or $p\,s$, will determine the ogee $n\,s\,q$. The quarter round is determined by ſo deſcribing an arc from a point $r$ in $p\,q$ produced, that it ſhall meet the hind part of the baſe-ring within one of ſuch parts, as the diameter of the ſhot contains twenty-four. The breadth of the ſhell is equal to ſix ſuch parts, and the diameter of the vent is a fifth part of an inch.

As to the muzzle (ſee *fig.* 3.) take the right line B K, equal to twenty ſuch parts, B P equal to ſix ſuch parts, and draw P L equal to B P, and at right angles to B K. From the point K draw alſo a right line perpendicular to B K. Then if the right line joining the points B, L be produced to meet this laſt-mentioned perpendicular in the point I, an arc deſcribed from this point as a centre, with the radius I L or I K, will determine the cavetto, or concave quarter, round L K. And if through the point $a$, at the diſtance of four ſuch parts from B H, and parallel to the ſame, the right line $a\,r$ be drawn, in it take a point $r$ at equal diſtances from the point L, and the extremity of the hind part of the fillet for deſcribing from as a centre, the quarter round, with this diſtance as radius.

From this conſtruction, with twenty-one diameters of the ſhot, for the lengths of braſs guns reſpectively for land ſervice, from a 24 pounder incluſive downwards; and with 14 diameters of the ſhot for lengths of iron field pieces reſpectively, he has given us tables of the weights and dimenſions of each, which are the following.

Table of the weight and dimenſions of braſs guns for land-ſervice.

| Caliber. | Length. | | Weight. | | |
|---|---|---|---|---|---|
| | ft. | in. | cwt. | qr. | lb. |
| 6 pounder | 6 | 1 | 8 | 0 | 4 |
| 9 pounder | 7 | 0 | 12 | 0 | 6 |
| 12 pounder | 7 | 8 | 16 | 0 | 8 |
| 18 pounder | 9 | 0 | 24 | 0 | 12 |
| 24 pounder | 9 | 8 | 32 | 0 | 16 |
| 32 pounder | 9 | 8 | 42 | 0 | 20 |
| 42 pounder | 9 | 8 | 52 | 0 | 24 |

Table of the weight and dimenſions of iron field-pieces.

| Caliber. | Length. | | Weight. | | |
|---|---|---|---|---|---|
| | ft. | in. | cwt. | qr. | lb. |
| 3 pounder | 3 | 3 | 2 | 1 | 0 |
| 6 pounder | 4 | 1 | 4 | 2 | 0 |
| 9 pounder | 4 | 8 | 6 | 3 | 0 |
| 12 pounder | 5 | 1 | 9 | 0 | 0 |
| 18 pounder | 5 | 10 | 13 | 2 | 0 |
| 24 pounder | 6 | 5 | 18 | 2 | 0 |

He gives another general conſtruction for braſs battering pieces on the ſuppoſition that the length, A B (ſee *fig.* 1.) of each is only equal to eighteen diameters of its ſhot, with all the other parts of the conſtruction remaining the ſame as above.

From this conſtruction he gives another table for braſs batttering pieces, and compares them with the old, as follows, Lengths and weights of braſs battering pieces.

| Old Pieces. | | | | | | New Pieces. | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Caliber. | Length. | | Weight. | | | Caliber. | Length. | | Weight. | | |
| | ft. | in. | cwt. | qr. | lb. | | ft. | in. | cwt. | qr. | lb. |
| 6 pounder | 8 | 0 | 19 | 0 | 0 | 12 pounder | 6 | 7 | 13 | 2 | 0 |
| 9 pounder | 9 | 0 | 25 | 0 | 0 | 18 pounder | 7 | 6 | 20 | 1 | 0 |
| 12 pounder | 9 | 0 | 29 | 0 | 0 | 24 pounder | 8 | 4 | 27 | 0 | 0 |
| 18 pounder | 9 | 6 | 48 | 0 | 0 | 32 pounder | 9 | 2 | 36 | 0 | 0 |
| 24 pounder | 9 | 6 | 51 | 0 | 0 | 36 pounder | 9 | 6 | 40 | 2 | 0 |
| 32 pounder | 10 | 0 | 55 | 0 | 7 | 42 pounder | 10 | 0 | 47 | 1 | 0 |
| 42 pounder | 9 | 6 | 61 | 2 | 10 | 48 pounder | 10 | 6 | 54 | 0 | 0 |

Theſe conſtructions are on the ſuppoſition that the guns are cylindric as far as the charges reach, and from thence conical to the mouth. The centre line of the trunnions is alſo ſuppoſed to interſect the longitudinal axis of the bore of each gun at right angles, to prevent it, when fired, from injuring or deſtroying its carriage, which it will ſoon do if the ſaid line be lower.

The quantity and weight of metal in a gun by this conſtruction he determines in the following manner.

Take the diameter of the gun acroſs the centre of the bore at the muzzle without the mouldings, which is equal to forty-three ſuch parts as the twenty-four, into which the diameter of the ſhot is ſuppoſed to be divided, and the ſquare of it is - - - 1849

To this he adds the ſquare of ſixty-one, the number of ſuch parts in the diameter of the gun at the vent-aſtragal - - - 3721

To theſe he adds the rectangle under theſe two diameters or 43 × 61 - - - 2623

The ſum of theſe three products is - 8193

The third part of this ſum is - - 2731

Which multiplied by 392, the number of ſuch parts in the length D B as the twenty-four, into which the diameter of the ſhot is ſuppoſed to be divided, gives - - - 1070552

To this content add the ſquare of the diameter 61 by 40 the number of ſuch parts in the length A D 148840

To theſe two contents add four times the cube of eighteen ſuch parts for the contents of the trunnions, caſcable, and mouldings - 23328

And the ſum will be equal to - 1242720

From this ſum of theſe three contents deduct the ſquare of twenty-five, the number of ſuch parts in the diameter of the bore multiplied by its length 416 in ſuch parts - - - 260000

And the remainder will be equal to - 982720

Which content reduced in the proportion of the area of a circle to the ſquare of its diameter gives 771826 for the number of cubic ſuch parts, as the twenty-four, into which the diameter of the ſhot is ſuppoſed to be divided, that expreſs the ſolid contents of metal in the gun.

But the number of cubic parts in a ball, of which the diameter is equal to twenty-four parts, is about 7238.2464, by which, if 771826 be divided, we get 106.21 nearly, which increaſed in the proportion of the weight of gun metal to that of caſt iron, or of 8784 to 7425, becomes 125.65 nearly, or 126 in whole numbers nearly.

Whence it is manifeſt that this conſtruction gives the weight of each gun, equal to about 126 times the weight of its ſhot ſuppoſing the diameter of the bore to be to that of the ſhot as 25 to 24, a proportion, however, that certainly leaves by far too much windage. Thus a nine-pounder braſs gun by it will weigh 1134 lb. or 10 cwt. and 14 lb.

He then gives a general conſtruction for battering and garriſon iron cannon ſuppoſing the length A B of each to be equal to twenty-one diameters of its ſhot.

He ſuppoſes the diameter of the ſhot to be divided into twenty-four equal parts as in the preceding conſtruction, and makes the diameter of the bore equal to twenty-five ſuch parts. He makes the length from A, the hind part of the baſe-ring, to D, the fore-part of the vent-aſtragal, equal to forty-eight ſuch parts. He gives a thickneſs to the metal at A and D, taken from the bore, equal to twenty-five ſuch parts, or to one diameter of the bore; and he makes its thickneſs at B, the mouth of the piece, equal to twelve ſuch parts, or to half the diameter of the ſhot.

He ſuppoſes the centre line of the trunnions to interſect the axis of the bore at right angles, at the diſtance of three-ſevenths of the whole length of the gun, or nine diameters of the ſhot from A, the hind part of the breech. He makes the diameter of each of them equal to one diameter of the ſhot, and the length of each, free from the projection of the ſecond reinforce ring, equal to the ſame.

By this conſtruction he allows about two hundred weight of metal for every pound of the ſhot's weight, or makes the weight of each gun equal to about 224 times that of its ſhot. And from this proportion is derived the following table for

BATTERING AND GARRISON IRON-PIECES.

| Caliber. | Length. | | Weight. | | |
|---|---|---|---|---|---|
| | ft. | in. | cwt. | qr. | lb. |
| 3 Pounder | 4 | 10 | 6 | 0 | 0 |
| 4 Pounder | 5 | 4 | 8 | 0 | 0 |
| 6 Pounder | 6 | 1 | 12 | 0 | 0 |
| 9 Pounder | 7 | 0 | 18 | 0 | 0 |
| 12 Pounder | 7 | 8 | 24 | 0 | 0 |
| 18 Pounder | 9 | 0 | 36 | 0 | 0 |
| 24 Pounder | 9 | 8 | 48 | 0 | 0 |
| 32 Pounder | 9 | 8 | 56 | 0 | 0 |

The thirty-two pounder is the only gun in this table that is ſhorter than twenty-one diameters of its ſhot, being only about nineteen of the ſame. It is alſo heavier by two hundred weight, than two-hundred and twenty-four times the weight of its ſhot. For theſe deviations, however, from his general rule, he has aſſigned no reaſons. And for them we are inclined to think, that no good ones can be given. We are alſo of opinion, that a much ſmaller weight of metal for every pound of the ſhot's weight would be perfectly ſufficient.

In his conſtruction of braſs guns for ſhips, he ſuppoſes AB, the length of the piece, to be equal to fifteen times only the diameter of the ſhot; which diameter he divides, as above, into twenty-four equal parts, making the diameter of the bore equal to twenty-five ſuch parts.

He makes the diſtance from A, the hind part of the baſe-ring, to D, the fore part of the vent-aſtragal, equal to forty ſuch parts; the breech AC, equal to eighteen, the thickneſs of the metal at A, and at D, equal to twenty, and at B, the mouth of the piece, equal to ten. The reſt of the conſtruction is the ſame as above, with this exception, that the diameter, as well as the length of each of the trunnions, inſtead of being equal to one diameter of the ſhot, or twenty-four ſuch parts, is only equal to twenty.

By a ſimilar computation to that made uſe of above, it appears that this conſtruction allows about one hundred and twenty-four pounds of gun-metal for every pound of the ſhot's weight, or that the weight of each gun is by it about one hundred and twenty-four times that of its ſhot, from which proportion, the following table is very nearly framed.

Brass Ship Guns.

| Caliber. | Length. | | Weight. | | |
|---|---|---|---|---|---|
| | ft. | in. | cwt. | qr. | lb |
| 3 Pounder | 3 | 6 | 5 | 1 | 17 |
| 6 Pounder | 4 | 4 | 6 | 2 | 14 |
| 9 Pounder | 5 | 0 | 10 | 0 | 0 |
| 12 Pounder | 5 | 6 | 13 | 1 | 3 |
| 18 Pounder | 6 | 4 | 20 | 0 | 0 |
| 24 Pounder | 7 | 0 | 26 | 2 | 7 |
| 32 Pounder | 7 | 6 | 35 | 1 | 17 |
| 36 Pounder | 7 | 10 | 40 | 0 | 0 |
| 42 Pounder | 8 | 4 | 46 | 2 | 0 |
| 48 Pounder | 8 | 6 | 53 | 0 | 14 |

In his general conſtruction for iron ſhip-guns, he likewiſe ſuppoſes the length of each piece to be equal to fifteen diameters of its ſhot; the diameter of the ſhot to be divided into twenty-four equal parts; the diameter of the bore to be equal to twenty-five ſuch parts; the diſtance from A, the hind part of the baſe-ring, to D, the fore part of the vent-aſtragal, to be equal to forty ſuch parts; the breech AC to be equal to twenty-four ſuch parts, or to one diameter of the ſhot; the thickneſs of the metal at the vent to be equal to one diameter, and at the mouth to half a diameter.

It appears by computation, that the quantity of metal, allowed by this conſtruction, is at the rate of about one hundred and forty pounds, or of one hundred weight and one quarter to every pound weight of the ſhot; or that each gun is by it about one hundred and forty times as heavy as its ſhot; from which proportion the following table is derived.

| Caliber. | Length. | | Weight. | | |
|---|---|---|---|---|---|
| | ft. | in. | cwt. | qr. | lb. |
| 3 Pounder | 3 | 6 | 3 | 3 | 0 |
| 6 Pounder | 4 | 4 | 7 | 2 | 0 |
| 9 Pounder | 5 | 0 | 11 | 1 | 0 |
| 12 Pounder | 5 | 6 | 15 | 0 | 0 |
| 18 Pounder | 6 | 4 | 22 | 2 | 0 |
| 24 Pounder | 7 | 0 | 30 | 0 | 0 |
| 32 Pounder | 7 | 6 | 40 | 0 | 0 |
| 42 Pounder | 8 | 4 | 52 | 2 | 0 |
| 48 Pounder | 8 | 6 | 60 | 0 | 0 |

In conſtructing light field-pieces, he makes the length of each equal to fourteen diameters of its ſhot, ſuppoſes the diameter of the ſhot to be divided into twenty-four equal parts, and the diameter of the bore to be equal to twenty-five ſuch parts, or to be to that of the ſhot as twenty-five to twenty-four.

He makes A C, the thickneſs of the breech, equal to fourteen ſuch parts, the thickneſs of metal at the vent equal to ſixteen, or two thirds of the diameter of the ſhot, at the mouth equal to eight ſuch parts, or one third part of ſaid diameter; and the diſtance from A, the hind part of the baſe-ring, to D, the fore part of the vent-aſtragal, equal to thirty-nine ſuch parts.

Under the caſcable in each of theſe light pieces there is a ring of metal caſt, (ſee *fig.* 2.) for faſtening the head of the ſcrew, that is employed inſtead of coins or wedges for elevating or lowering the gun. This ring is deſcribed from the ſame centre and with the ſame radius that the neck is. The diameter of the hole for receiving the bolt is equal to five parts, and the thickneſs of the ring to four. The diameter, as well as the length of each trunnion, is equal to ſixteen parts, and the reſt of the conſtruction is the ſame as in the firſt.

By it the quantity of metal is at the rate of about eighty five pounds for every pound of the ſhot's weight, or the weight of each gun is about eighty-five times as great that of its ſhot, which proportion gives the following table.

Field Pieces.

| Caliber. | Length. | | Weight. | | |

### *Of ſhort Cannon, ſuch as Mortars, Howitzers, and Carronades.*

Mortars are a ſort of cannon with ſhort and large bores, with chambers, and are thought to be the firſt pieces of artillery that were uſed, as they were employed to throw balls of red-hot iron and ſtones long before the invention of ſhells, which is aſcribed to a native of Venlo, who at a feſtival celebrated in honour of the duke of Cleves, threw a number of them, one of which, falling on a houſe, ſet fire to it, which rapidly communicating to other building, reduced the greateſt part of the town to aſhes. Mortars which are generally believed to be a German invention, are ſaid to have been actually made uſe of for military purpoſes in 1435, when Naples was beſieged by Charles the 8th. But whether ſhells were then thrown out of them is uncertain. It is known, however, to a certainty, that ſhells were thrown from mortars at the ſiege of Wachlendonk, in Guelderland, by the earl of Mansfield, in 1588. Cyprian Lucas wrote upon the method of filling and throwing ſhells, in his appendix to the colloquies of Tartaglia, printed at London in 1588, in which performance, the method of compoſing and throwing carcaſes as well as various ſorts of fire-works, is alſo ſhewn.

Mr. Malter, an Engliſh engineer, is ſaid to have firſt taught the French the method of throwing ſhells, which they practiſed at the ſiege of Lamothe in 1634.

Mortars, however, have been long made uſe of, chiefly for throwing *hollow balls*, called *ſhells*, filled with a ſufficiency of powder for burſting them, which, falling on any building, or into the works of a fortification, or among troops encamped, forming in order of battle, in column, or landing from veſſels or boats, &c. are burſt or broken by the force or exploſion of the powder in them into a number of pieces or fragments, which, flying in all directions, occaſion trepidation and confuſion, and are deſtructive to every thing within their reach. They are alſo frequently made uſe of for throwing carcaſes, which are a ſort of ſhells with five holes filled with pitch and other combuſtibles, in order to ſet fire to buildings. Baſkets full of ſtones about the ſize of a man's fiſt, or of hand-grenades, are ſometimes thrown from them during a ſiege into the covert-way, on the men employed in defending it. The ingenious general Deſaguliers contrived a method of throwing bags from them filled each with from four to ſix hundred ſhot of different dimenſions. The effect of ſuch an application of them, by pouring down ſhot ſomewhat like a ſhower of hail on ſpots three hundred feet at leaſt each of them in circumference, muſt be awful and tremendous to troops moving in column, forming in line of battle, paſſing a defile, landing, &c. &c.

Mortars are, in this country, commonly diſtinguiſhed by the diameters of their bores. Thus a thirteen inch mortar, a ten inch mortar, an eight inch mortar, are thoſe which have the diameters of their bores reſpectively equal to thirteen, ten, and eight inches. Theſe are the three largeſt ſized mortars employed by us for land ſervice. Beſides them there are two ſmaller ſized ſorts of mortars, one of which is called a royal, having the diameter of its bore equal to 5.62 inches, and the other a coehorn, taking its name from its inventor, Mr. Coehorn, the celebrated engineer, and having the diameter of its bore equal to 4.52 inches.

The principal part of a mortar on the outſide, (ſee *fig.* 4.) are, A the chace, including the muzzle, B the reinforce, C the breech, and D the trunnions. The ſmaller exterior diviſions are, the vent, the dolphins, the vent-aſtragal and fillets, the breech-ring and ogee, the reinforce ring and ogee, the reinforce-aſtragal and fillets, the muzzle aſtragal and fillets, the muzzle-ring and ogee, and the ſhoulders.

The interior parts are, the chamber which receives the charge of powder, the bore where the ſhell is lodged, the mouth, and the vent.

The chamber is formed variouſly by different nations. The Spaniards chiefly uſe the ſpheric ; the French, the Germans, and the Dutch make uſe of various forms for it, as the conic, the cylindric, the bottled or the concave ; the Portugueſe the parabolic, and the Engliſh have uſually made it in form of a fruſtum of a cone. No very ſatisfactory reaſons, however, have been aſſigned for this variety.

Mortars are made of braſs, iron, or ſtone.

Land-mortars are thoſe that are uſed in ſieges and on other land ſervice mounted on beds. Both they and their beds are tranſported on truck-carriages. There is alſo a kind of land-mortar invented by count Buckeburg, which is mounted on a travelling carriage, and may be elevated to any degree at pleaſure.

Sea-mortars are thoſe that are made uſe of for ſea-ſervice, ſuch as the bombardment of places by water, &c. As the objects they are fired at and intended to deſtroy are generally at greater diſtances from them than thoſe to which land-mortars are required or expected to throw their ſhells, they are ſomewhat longer than them and much heavier.

Partridge-mortar is a common mortar ſurrounded by thirteen other little mortars bored round its circumference in the body of the metal. The large mortar in the centre is loaded with a ſhell, and the others with grenades. When it is fired by the vent the fire is ſo communicated at the ſame time to the ſmall ones, that both the ſhell and grenades go off at once. The French uſed them in the war of 1701, at the defence of Bouchain, in 1702, and at the ſiege of Liſle, in 1708.

Hand-mortars were frequently made uſe of before the invention of coehorns. They were fixed to the ends of ſtaves about four feet and a half long, of which the other ends were ſhod with iron for ſticking them in the ground. A bombardier elevated one of them at pleaſure with one hand, whilſt he fired it with the other.

The dimenſions of braſs land-mortars now made uſe of in our ſervice are the following.

| | Inches. | Inches. | Inches. | Inches. | Inches. |
|---|---|---|---|---|---|
| Diameter of the bore - - - - | 13 | 10 | 8 | 5.8 or<br>5.62 rather. | 4.6 or<br>4.52 rather. |
| Total length of the mortar - - - - | 44 | 33 | 25.5 to 26 | 16 to 16.[illegible] | 1[illegible].5 |
| Diſtance from the muzzle to the reinforce - - | 15.25 | 10 | 8.5 | 4.75 | 4.[illegible] |
| The length of the reinforce - - - - | 8.75 | 8.1 | 5 | 5 | 3.9 |
| The length of the trunnions from end to end - - | 32.5 | 26 | 20 | 12 | 9.2 |
| Diameter of the trunnions - - - - | 7.15 | 6.3 | 5 | 2.75 | 2.15 |
| The length of the bore - - - - | 24 | 18 | 13 | 8.5 | 7 |
| Length of the chamber - - - - - - | 12 | 7.8 | 7.75 | 4.3 | 3.7 |
| Greateſt diameter of the chamber - - - - | 6.6 | 4.5 | 4 | 3 | 2.7 |
| Leaſt diameter of the chamber - - - - | 6 | 3.6 | 3.4 | 2.4 | 1.4 |
| The diameter of the muzzle-ring - - - - | 21 | 15.15 | 11.2 | 8 | 6.4 |
| The breadth of the muzzle-ring - - - - | 1.1 | 0.8 | 0.7 | 0.6 | 0.5 |
| The breadth of the aſtragals and fillets - - - | 1.25 | 1 | 0.75 | 0 | 0 |
| Their diſtance from the muzzle-ring - - - - | 1.5 | 1 | 1 | 0 | 0 |
| The diameter near the muzzle aſtragal - - - | 18.1 | 13.2 | 10 | 6.9 | 5.6 |
| The diameter near the reinforce - - - - | 18.1 | 13.2 | 10 | 6.9 | 5.6 |
| The diameter of the reinforce - - - - | 21 | 15.15 | 15.1 | 8 | 6.4 |
| The breadth of the ogees - - - - | 1.5 | 1 | 1 | 0 | 0 |
| The diameter behind the breech-aſtragal - - - | 18.1 | 13.2 | 9.8 | 6.9 | 5.9 |
| | lb. oz. gr | lb. oz. gr | lb. oz. gr. | lb. oz. gr. | lb. oz. gr. |
| Chambers contain powder - - - - | 9 1 8 | 4 0 0 | 2 0 10 | 1 0 10 | 0 8 0 |

It is proper to obſerve, that the extremity of the bore next to the chamber is made round, and formed by an arc, which has its radius equal to that of the bore, and is terminated by the lines that form the chamber. The bottom of the chamber itſelf is ſemicircular. And the outſide of the metal is determined by a circular arc deſcribed from the ſame centre as the bottom of the chamber, and touching the lines drawn parallel to its ſides.

By means of theſe data, and the foregoing dimenſions accurately delivered, ſuch mortars may eaſily be conſtructed from the plate which exhibits the form of one.

The following are the dimenſions of the ſea-mortars that are uſed at preſent in our ſervice, (ſee *figs*. 5. and 6.), which are of two ſizes only, viz. of thirteen inches and ten inches bore.

| | Inches. | Inches. |
|---|---|---|
| The diameter of the bore - - | 13 | 10 |
| The whole length of the mortar - | 63 | 56 |
| The diſtance from the muzzle to the reinforce - - - | 21 | 20 |
| The length of the reinforce - - | 18 | 12 |
| The length of the bore - - | 24 | 30 |
| The length of the chamber - - | 21 | 15 |
| The greateſt diameter of the chamber | 8.5 | 6.6 |
| The leaſt diameter of the chamber - | 7 | 6 |
| The breadth of the muzzle-ring - | 3 | 2.4 |
| The breadth of the muzzle, ogee, and fillet - - - - - | 1.9 | 0 |
| From the muzzle to the aſtragal - | 0 | 0.4 |
| The breadth of the aſtragal - - | 0 | 1.6 |
| The breadth of the reinforce ring - | 1.9 | 0 |
| The breadth of the ogee next to the reinforce-ring - - - | 4.5 | 2.2 |
| The breadth of the chace-ring - | 1.5 | 0 |
| The breadth of the chace-ogee - | 2.2 | 0 |
| The breadth of the chamber-aſtragal | 0 | 1.6 |
| The thickneſs of the metal at the muzzle - - - - | 4.7 | 2.8 |
| The thickneſs of the metal at the muzzle-ring - - - - | $5\frac{3}{4}$ | 6 |
| The thickneſs of the metal near the reinforce - - - - | 4.7 | 3.3 |
| The thickneſs of the metal at the reinforce - - - - | 8 | 6 |
| The thickneſs of the metal behind the reinforce - - - - - | 9.5 | 6 |
| The length of the trunnion from end to end - - - - - | 45.4 | 36 |
| Its greateſt diameter - - - | 12 | 8 |
| Its leaſt diameter - - - - | 10 | 8 |
| Length or the part diminiſhed at each end - - - - - - | 6 | 0 |
| | lb. oz. gr. | lb. oz. gr. |
| The chamber contains powder - - | 32 0 0 | 12 8 0 |

Thickneſs of the metal at the muzzle, and near the rein-force is taken or meaſured from the lines produced, which determine the bore of the mortar; and behind the reinforce it is taken or reckoned from the lines which form and terminate the chamber. The round part, or the breech of the mortar, is circular, and in the ten-inch mortar is deſcribed from the ſame center that the bottom of its chamber is deſcribed from. But in the thirteen-inch mortar it is deſcribed from a center about three inches and a half nearer to the end of the mortar than that from which the bottom of its chamber is deſcribed. And in both theſe arcs ought to touch right lines drawn parallel to the ſides of the chambers.

The invention of Howitzers is of a much later invention than that of mortars. The Howitzer is, however, one of the moſt uſeful pieces of artillery, as it can be employed on moſt occaſions either as a cannon or mortar, and is eaſily moved by an army from place to place. It has its trunnions nearly in the middle, and is mounted on a carriage like a travelling gun carriage. The ten-inch howitzer is the largeſt in our ſervice, and is not much made uſe of. It has been reduced but little as to length, but materially in point of weight from what it was formerly. The following are the dimenſions of the eight inch howitzer that we now uſe. See *fig*. 7.)

| | Inches. |
|---|---|
| The diameter of the bore - - - - | 8 |
| The diſtance from the muzzle to the reinforce - - - - - | 16 |
| The length of the reinforce - - | 10.7 |
| The whole length of the howitzer - | 37.4 |
| The length of the bore - - - | 25.9 |
| The length of the chamber - - | 9.9 |
| The greateſt diameter of the chamber - | 4.6 |
| The leaſt diameter of the chamber - | 4 |
| The breadth of the muzzle ring - - | 1.25 |
| The diſtance from the muzzle ring to the aſtragal - - - - - | 4.6 |
| The breadth of the aſtragal - - | 0.7 |
| The breadth of the ogee before the reinforce - - - - | 1.4 |
| The breadth of the ogee behind the reinforce - - - - | 0. or it has none. |
| The breadth of the aſtragal behind the reinforce - - - - | 0.7 |
| The breadth of the baſe-ring - - | 1.25 |
| The thickneſs of the metal at the muzzle | 2.15 |
| The thickneſs of the metal at the muzzle ring - - - - | 3.4 |
| The thickneſs of the metal near the reinforce - - - - - - | 2.6 |
| The thickneſs of the metal at the reinforce | 3.4 |
| The thickneſs of the metal behind the reinforce - - - - | 2.5 |

| | Inches. |
|---|---|
| The diameter of the baſe-ring - - | 14.7 |
| The diameter at the vent-aſtragal - | 12.5 |
| The diameter of the caſcable - - | 7.6 |
| The diameter of the button - - | 5 |
| The diameter of the neck - - - | 3.5 |
| The breadth of the firſt ogee and fillets | 0.9 |
| The breadth of the ſecond ogee and fillets | 0.9 |
| The diameter of the firſt fillet - - | 9.5 |
| The diameter of the ſecond fillet - | 4.5 |
| The length and the diameter of each trunnion - - - - | 4.4 |
| The diſtance from the fore part of the reinforce to the trunnions - - - | 1.2 |
| | lb. oz. |
| The chamber contains powder - - | 4 0 |
| | cwt. qr lb. |
| The weight of the howitzer - - | from 12 3 0 to<br>12 1 11 |

The conſtructions of howitzers are almoſt as variable and uncertain as thoſe of mortars, as moſt artilleriſts have notions of their own reſpecting the figures of both. Our mortars have not been conſtructed from principles well aſcertained, or from any general rule applicable to all ſizes of them. Neither have our howitzers. Mr. Muller was the firſt that we know of, that made even any attempt at ſuch general rules for the conſtruction of either of all ſizes. But he neither demonſtrates the principles of his general rules, nor proves them to be unexceptionable. His general dimenſions for land mortars ſuppoſing the diameter of the bore of each to be divided into thirty equal parts are the following. See *fig*. 8.

| The diameter of the bore - - - | Diameter of the bore divided into 30 equal parts. | Diameter of the bore divided into 30 equal parts. | Diameter of the bore divided into 30 equal parts. |
|---|---|---|---|
| The diameter of the chamber - - - | 10 ſuch parts | 10 ſuch parts | 10 ſuch parts |
| The length of the bore equal to - - - | 54 | 45 | 40 |
| The length of the chamber equal to - - | 22 | 21 | 20 |
| The diſtance from the end of the chamber to the end of the mortar - - - - - - | 16 | 15 | 14 |
| The total length of the mortar equal to - - | 92 | 81 | 74 |
| The diſtance from the mouth *a* to the reinforce *b* - | 30 | 26 | 21 |
| The length of the reinforce *b c* equal to - - | 18 | 14 | 14 |
| The breadth of the muzzle-ring and fillets - - | 3.5 | 3 | 3 |
| The breadth of the ogee next to it - - - | 3 | 2 | 2 |
| The diſtance from the ogee to the muzzle aſtragal - | 5 | 4 | 3 |
| The breadth of the aſtragal and fillets - - | 2.5 | 2 | 2 |
| The breadth of the ogee before the reinforce - | 3 | 2 | 2 |
| The breadth of the two ogees and fillets behind the reinforce - - - - - - - | 6 | 5 | 4 |
| The thickneſs of the metal at the muzzle - - | 5 | 4.5 | 4 |
| The thickneſs of the metal near the reinforce - - | 6 | 5 | 4.5 |
| The thickneſs of the metal at the reinforce - - | 7 | 5.5 | 5 |
| The thickneſs of the metal at the chamber - - | 12 | 12 | 12 |
| The thickneſs of the metal at the muzzle-ring - - | 6.5 | 5.5 | 5 |
| The diameter of the trunnions - - - | 14 | 13 | 12 |
| The length of the trunnions from the mortar - - | 15 | 14 | 13 |
| The cube of the diameter of the bore in inches - - | $d^3$ | $d^3$ | $d^3$ |
| The quantity of powder in lb. which the chamber contains is nearly equal to - - - - | $\frac{d^3}{421}$ | $\frac{d^3}{442}$ | $\frac{d^3}{466}$ |
| The weight of the mortars equal nearly to - - | $\frac{5d^3}{6}$ | $\frac{2d^3}{3}$ | $\frac{3d^3}{5}$ |

Without attempting, as we have already obſerved, to demonſtrate the principles of this general conſtruction, he tells us that he has endeavoured to diſpoſe, diſtribute, or arrange the metal in ſuch a manner, as to make the relative degrees of ſtrength in the different parts proportional to the forces which act upon them. He thinks the thickneſs of metal at the chamber ſufficient, as it exceeds by two parts the diameter thereof, which is more in proportion than what is ever allowed to any braſs gun whatever. He obſerves that though the mortar on the outſide ought to be conical from the chamber to its mouth, to ſuit the action of the powder, he has, in compliance with common practice, given it a reinforce juſt ſufficient to admit of an ogee.

He tells us he does not pretend to determine the true poſition of the vent, though he had always found that the nearer it was placed to the bottom of the chamber, the farther the mortar threw the ſhell with a given charge of powder. As he made theſe experiments, however, with only a three-inch mortar, he apprehends that no juſt concluſions can be drawn from them with regard to mortars of a larger ſize.

He delivers it as his opinion, that the cylindric figure is the beſt for the chambers of ſuch mortars, obſerving, that though the bottled or concave chambers, or thoſe which have the ſmalleſt entrances, will throw ſhells farther than any others; yet in thoſe which require but little powder their entrances would be too narrow, and it would be troubleſome to clean them; whereas, when they are cylindrical, they are very nearly as advantageous for throwing ſhells without being ſubject to theſe inconveniencies.

He informs us, that he and general Deſaguliers made ſeveral experiments with chambers of different forms or figures, which contained the ſame quantity of powder, and uniformly found, that the cylindric threw the ſhell farther than any other, of which the entrance was larger, particularly when they were not quite filled; that they alſo made ſome experiments with cartridges of common writing paper holding charges of powder only equal reſpectively to half the content of the chamber, and found that when ſuch a cartridge was ſo placed in the chamber as to be cloſe to the ſhell, leaving a vacuity between it and the bottom, it threw the ſhell nearly twice as far as it did when it touched the bottom of the chamber, and left a vacancy between itſelf and the ſhell; that theſe experiments were repeated ſeveral times, and always gave the ſame reſult. He alſo informs us, that on filling the chamber partly with powder and putting a piece of common writing paper upon it, he found that the ſhell went much farther than the ſame charge without paper threw it; that they likewiſe made repeated experiments with a cylindrical chamber, and a conical one of the ſame length and content, that had its diameter at the bottom equal only to half that at its entrance, and obſerved, that when theſe chambers were not quite filled, the cylindric one uniformly threw the ſhell much farther than the other did.

The firſt ſort of mortars in this general conſtruction, or thoſe of which the weights are expreſſed by $\frac{5d^3}{6}$, have the ſame lengths which the land mortars have that we now make uſe of. The ſecond, or thoſe of which the weights are expreſſed by $\frac{2d^3}{3}$, are of the ſame lengths with thoſe the French have been in the practice of uſing. And the third ſort, that have their weights denoted by $\frac{3d^3}{5}$, are ſhorter than either. In each of them the chamber is cylindric, and the bottom of it a hemiſphere. And the round part of the mortar is deſcribed from the ſame centre as the bottom of the chamber.

In his general conſtruction for ſea mortars the dimenſions are the following. See *fig.* 9. Our ſea mortars, as we have already obſerved, are of two ſizes only, viz. of 13 inches and 10 inches.

| The diameter of the bore | Diameter of the bore divided into 30 equal parts. | Diameter of the bore divided into 30 equal parts. |
|---|---|---|
| The length of the bore | 75 ſuch parts | 75 ſuch parts |
| The diameter of the chamber | 15 | 15 |
| The length of the chamber | 33 | 33 |
| The diſtance from the end of the chamber to the end of the mortar | 20 | 20 |
| The total length of the mortar | 128 | 128 |
| The diſtance from the muzzle *a*, to the reinforce *b* | 43 | 43 |
| The length of the reinforce *bc* | 28 | 28 |
| The thickneſs of the metal at the muzzle, the mouldings excepted | 8 | 7 |
| The thickneſs of the metal near the reinforce | 9 | 8 |
| The thickneſs of the metal at the reinforce | 10 | 9 |
| The thickneſs of the metal at the chamber | 16 | 16 |
| The breadth of the muzzle-ring and fillets | 4 | 4 |
| The breadth of the ogee next to it as alſo of that before the reinforce | 3 | 3 |
| The diſtance from the ogee to the muzzle-aſtragal | 6 | 6 |
| The breadth of the aſtragal and fillets | 3 | 3 |
| The breadth of the ogee behind the reinforce | 4 | 4 |
| The muzzle-ring projects the metal by | 1.5 | 1.5 |
| The diameter of the trunnions | 18 | 18 |
| The length of each trunnion from the mortar | 20 | 20 |
| The cube of the diameter of the bore | $d^3$ | $d^3$ |
| The quantity of powder in lbs. which the chamber contains | $\frac{d^3}{126}$ | $\frac{d^3}{126}$ |
| The weight of the metal | $2.1 \times d^3$ | $1.8 \times d^3$ |

The arc which determines the round part of each mortar is deſcribed from the ſame centre which the arc, that determines the bottom of the chamber, is deſcribed from.

The weights of our preſent ſea mortars, and the quantities of powder which their chambers contain, compared with thoſe which theſe conſtructions give, will ſtand as follows.

| | Inches. | | | Inches. | | |
|---|---|---|---|---|---|---|
| The diameter of the bore | 13 | | | 10 | | |
| | cwt. | qr. | lb. | cwt. | qr. | lb. |
| The weights of our preſent ſea-mortars | 82 | 0 | 0 | 33 | 0 | 0 |
| The weights of ſea-mortars by the firſt of theſe two conſtructions $=2.1\times d^3$ | 41 | 0 | 19 | 18 | 2 | 19 |
| The weights of ſea-mortars by the ſecond of theſe conſtructions expreſſed by $1.8\times d^3$ | 35 | 1 | - | 16 | 0 | 7 |
| | lb. | oz. | gr. | lb. | oz. | gr. |
| The quantities of powder, which the chambers of our preſent ſea-mortars contain | 32 | 0 | 0 | 12 | 8 | 0 |
| The quantities of powder, which the chambers of ſea-mortars by theſe conſtructions would contain | 17 | 7 | 0 | 8 | 0 | 0 |

Beſides theſe kinds of mortars for throwing ſhells and carcaſſes, there is another ſort of mortar for throwing ſtones either by the beſieged from the body of the place, the outworks, or covert way into the beſiegers approaches on the glacis, &c. or by the beſiegers into the covert way, &c. as they approach the ſame. There are no ſuch mortars employed in our ſervice; becauſe hand-grenades, or ſmall ſhells thrown from a common mortar with ſmall charges of powder, anſwer the purpoſe intended much better than ſtones.

The following, however, are the dimenſions of a fifteen-inch ſtone mortar, ſuppoſing the diameter of the bore to be divided into thirty equal parts. See *fig.* 12.

| | |
|---|---|
| The diameter of the bore divided into | 30 equal parts |
| The length of the bore | 37 ſuch parts |
| The length of the chamber | 16 |
| The greateſt diameter of the chamber | 8 |
| The leaſt diameter of the chamber | 6 |
| The diameter of the cylindric part to hold a wooden tompion | 14 |
| The depth or axis of that cylinder | 3 |
| The diſtance from the muzzle to the reinforce | 20.5 |
| The length of the reinforce | 8 |
| The thickneſs of the metal at the muzzle | 3.5 |
| The thickneſs of the metal at the reinforce | 4.5 |
| The thickneſs of ditto at the chamber-belt | 9 |
| The thickneſs of ditto at the entrance of the chamber | 6 |
| The chamber enters into the trunnions by | 2 |
| The breadth of the muzzle-ring and fillets | 3 |
| The breadth of the chamber-belt is equal to | 2 |
| The breadth of the ogee next to that belt | 3 |
| The cube of the diameter of the bore | $d^3$ |
| The quantity of powder in lbs. which the chamber contains | $\frac{d^3}{1102}$ |
| The weight of the metal contained in this mortar | $\frac{d^3}{3.1}$ |

The dimenſions, according to his conſtruction, of howitzers of three different weights, with the ſame bore, are the following. See *fig.* 10.

| | | | |
|---|---|---|---|
| The diameter of the bore divided into equal parts | 30 | 30 | 30 |
| The length of the bore | 90 | 90 | 97.5 |
| The diameter of the chamber | 15 | 15 | 15 |
| The length of the chamber | 33 | 33 | 33 |
| The diſtance from the muzzle *a*, to the reinforce *b* | 50 | 50 | 54.5 |
| The length of the reinforce *b c* | 34 | 34 | 37 |
| The diſtance from the reinforce *c*, to the end of the howitzer | 50 | 50 | 50 |
| The whole length of the howitzer | 134 | 134 | 141.5 |
| The thickneſs of the metal at the muzzle | 8 | 7 | 8 |
| The thickneſs of the metal near the reinforce | 9 | 8 | 9 |
| The thickneſs of the metal at the reinforce | 10 | 9 | 10 |
| The thickneſs of the metal at the chamber | 16 | 15 | 16 |
| The breadth of the muzzle-ring as alſo of the baſe-ring, fillets included | 5 | 5 | 5 |
| The breadth of each of the ogees, that behind the reinforce excepted | 3.5 | 3.5 | 3.5 |
| The diſtance between the muzzle ogee and aſtragal, as alſo between the breech ogee and aſtragal | 6 | 6 | 7 |
| The breadth of the muzzle-aſtragal and fillets, as alſo of the breech aſtragal and fillets | 3 | 3 | 3 |
| The breadth of the ogee behind the reinforce | 6 | 6 | 6 |
| The muzzle and baſe-rings project the metal each by | 1.5 | 1.5 | 1.5 |
| The length of the trunnions | 18 | 18 | 18 |
| The diameter of the trunnions | 15 | 15 | 15 |
| The diſtance of the trunnions from the fore end of the reinforce | 5 | 5 | 5 |
| The cube of the diameter of the bore | $d^3$ | $d^3$ | $d^3$ |
| The quantity of powder in lbs. which the chamber contains | $\frac{d^3}{116}$ | $\frac{d^3}{116}$ | $\frac{d^3}{116}$ |
| The weight of the howitzer | $2.25d^3$ | $1.97d^3$ | $2.4d^3$ |

The length of the caſcable is equal to 24 ſuch parts, the radius of the button to 8, and the ogee with the fillet included is equal to 4.

It is ſomewhat ſurpriſing that howitzers are not more made uſe of than they are even in the field. For they may be employed ſucceſsfully for throwing, not only large ſhells, but large, ſolid, or cored ſhot, either point blank, or with ſmall angles of elevation, and with charges of powder ſuited to different ranges and grazing diſtances to the great annoyance both of cavalry and infantry, particularly in column. They are alſo much fitter than guns for diſcharging grapes of ſmall ſhot and ſmall ſhells from ſhort diſtances at ſieges; and are peculiarly calculated for ſweeping or ſcouring the covert way along its ſeveral branches with ſhells fired *en ricochet*. No earthen works are proof againſt them when a judicious uſe is made of them. Even at ſieges, when the works have revetements, or demi-revetements of maſonry, as ſoon as the walls which ſupport the earth of the rampart and parapet are battered down, there is no ſpeedier or more effectual way of completing the breaches and rendering them practicable than by throwing ſhells into the earth where it is bared of maſonry. For they lodge or bury themſelves in it, and burſting operate as ſmall mines.

*Fig.* 11 repreſents a mortar with a bottled or concave chamber, the diameter, *a b*, of the entrance of which is a third part of the diameter of the bore. The diſtance from *a b* to *c d* drawn parallel and equal to it in the longitudinal ſection is equal to twenty-ſix ſuch parts as thoſe, of which the diameter of the bore contains thirty. The conjugate diameter of the chamber is equal to twenty ſuch parts. The form of the outſide of the mortar, where the chamber is, is ſimilar to that of the chamber itſelf. The thickneſs of the metal at the chamber is equal to ſixteen ſuch parts, and all the other dimenſions are the ſame as in the firſt conſtruction for mortars above.

As the entrance of the chamber has its diameter equal to a third part of the diameter of the bore of the mortar, it is large enough in one of either thirteen or ten inches for admitting a man's hand to clean it without inconvenience, and may therefore be loaded without difficulty.

Beſides theſe pieces of ordnance, there is another, that is now pretty generally uſed, and is called a carronade, from a foundery that has for a conſiderable time been carried on by a company under the name of the Carron company, on the banks of the river Carron in Scotland. The carronade is a gun of a ſort of intermediate length and weight between the cannon and the howitzer, and not a very ſhort howitzer, as the celebrated Dr. Hutton has inadvertently obſerved in his Mathematical Dictionary. The firſt ſuggeſter, propoſer, or inventor of it was the preſent learned and ingenious General Robert Melville, ſo well known for his talents as a military antiquarian, and the diſcoverer of the temporary Roman camps in North Britain. He at firſt ſuggeſted that not only ſolid but ſhell ſhot might be thrown from it, and afterwards that it might be employed for throwing carcaſſes and cored ſhot. The firſt gun of this nature was caſt and conſtructed according to his ſuggeſtions at Carron in 1779 after a rupture with France, and during the American war. The operation was performed under the directions of that very able founder, Charles Gaſcoigne Eſq. then director of that foundery.

The diameter of its bore was equal to eight inches, having the ſame caliber with an eight-inch mortar or howitzer.

The length of its bore including the chamber was equal to ſix diameters of the ſame very nearly, or to ſix times its caliber or four feet.

The diameter of its chamber was equal to the caliber of a forty-two pounder gun, and contained five pounds and a half of powder.

Its weight was nearly equal to that of the navy twelve pounder-gun, being equal to 31 cwt.

The ſhot was caſt in an eight-inch ſpherical iron mould, and the windage was formed by the retreat or ſhrinking of the metal of the ſhot in cooling, which when cold weighed about 68 pounds, or about four pounds leſs than a ſolid iron ſhot or ball eight inches in diameter, which weighs about 72 pounds very nearly. From this circumſtance it came to be called a 68 pounder, though its original propoſer or inventor gave it the name of a *ſmaſher* from its effects, particularly when fired with ſhot at timbers or wooden work. It was at firſt deſigned for a ſhip gun. And there is now in the poſſeſſion of General Melville a ſmall model of it mounted on its carriage on a ſmall platform, to one end of which is faſtened a wooden repreſentation, in miniature, of part of a ſhip's ſide, with a port, and the following inſcription in braſs, let in on the top thereof.

"Gift of the Carron company to Lieutenant General Melville, inventor of the ſmaſhers and leſſer carronades for ſolid, ſhip, ſhell, and carcaſs ſhot, &c. firſt uſed againſt French ſhips in 1779."

In the middle of the lower carriage there is a longitudinal groove, along which the gun on its upper carriage recoils. And when ſo mounted, it may be pointed in any angle leſs than forty degrees either to the right or left of this groove. A port or embrazure large enough for a 24 or 32 pounder gun is alſo ſufficiently large for receiving the ſmaſher or 68 pounder carronade.

Several experiments were made with one of this caliber the ſame year, viz. in 1779, at Carron, in the preſence of Sir Adolphus Oughton, K. B. then commander in chief in Scotland, General Melville, and many other officers, ſome of whom were of the corps of artillery and engineers, with ſuch ſucceſs, both in regard to the projectile force, with which the ſhell-ſhot were thrown, and not only the practicability but alſo the certainty of their producing powerful effects, by burſting wherever they ſhould penetrate, as perfectly convinced Sir Adolphus and all the reſt, that in all fit caſes, which might be many, by ſea as well as by land, for the uſe of this ſpecies of artillery, the introduction of ſuch pieces of ordnance both into his Majeſty's naval and military ſervice would be of the greateſt utility and advantage. Sir Adolphus thought it therefore his duty to tranſmit to government a fair and candid report of the experiments he had ſeen made, and a ſtatement of the advantages which he conceived might be obtained by a judicious and proper uſe of ſuch guns. It happened, however, that no encouragement was then given to the introduction of this ſpecies of cannon, though it was ſo reſpectably recommended and approved of by intelligent profeſſional men, becauſe it was regarded as a novelty, an innovation, and a departure from common hacknied practice and cuſtoms, by which public boards, that are but rarely compoſed of individuals of the firſt talents, liberality, and information, are for the moſt part too ſlaviſhly governed. The proprietors of the Carron foundery, however, were adviſed to try whether pieces of ſundry ſmaller dimenſions, caſt and conſtructed on the ſame principle, would not meet with a ſufficient ſale for private veſſels of war, as letters of marque and repriſals, and perhaps for ſome of the royal frigates. They made the trial, and ſucceeded. For, beſides a pretty frequent demand that was made for them during the remainder of that war for the uſe of the two former deſcriptions of veſſels, on account of the great advantages they were found in practice to poſſeſs over common guns of the ſame weights, and much ſmaller calibers, there were ſome of the larger ſort or of 8 inches caliber, called ſmaſhers by the original propoſer, introduced by degrees into the navy. Two of the naval officers, who firſt made uſe of them on board their ſhips, were Captain Keith Elphinſtone, now Admiral Lord Keith, and Captain Henry Trollope, now Sir Henry Trollope, the latter of whom, in a moſt remarkable inſtance, by means of two ſmaſhers which he had on board his frigate, beat off ſeveral of the enemy's, who were panicſtruck on viewing the ſize of ſome of the ſhot he fired into them.

Soon after the commencement of the royal war againſt France, in which Great Britain engaged early in 1793, carronades of various dimenſions, but few of the larger ſize, or ſmaſhers, improperly called 68 pounders from each of their ſolid iron-balls, which are not near ſo fit for ſea ſervice as hollow or cored ſhot of the ſame diameter, but much lighter, came rapidly into uſe in our ſhips of war and other armed veſſels, and often proved to be of the greateſt utility and advantage.

vantage. They have ever ſince been reckoned ſo uſeful, that there is now hardly a ſhip in our navy or an armed veſſel, that is altogether without them.

When the carronades were firſt introduced, they were meant chiefly for the defence of merchant ſhips, and were calculated, by their conſtruction, to be of ſuch lengths and weights as might be convenient for the ſizes of the veſſels that were to carry them, ſuppoſing each of them to be loaded with a twelfth part of the weight of its ſhot, as the ſervice-charge of powder. The Board of Ordnance was pleaſed to order a number of them for the navy: and their firſt warrant for about 1500 of them was completed before Mr. Gaſcoigne was certainly informed that the board had fixed on one-ninth inſtead of a twelfth part of the weight of the ſhot as the charge of powder for ſervice. Theſe were therefore reckoned both too light and too ſhort for the navy. And on the Board's afterwards ordering 20 carronades of each of the natures of 12, 18, 24, and 32 pounders, he very naturally took the liberty of adding both to the length and fortifications of each of them, ſo as to increaſe its ſtrength and power of reſiſtance to burſting, in proportion to this perhaps ill-judged addition to the charge of powder, ſubſtituting alſo a ſcrew inſtead of the quoin or wedge. Forty of them were proved at Woolwich, and were afterwards rejected on account of theſe very improvements.

The late colonel Fraſer, of the engineer corps, made a number of experiments at Leith with a ſmaſher, or 68 pounder carronade, both with its own ſolid ſhot and with common eight-inch ſhells, which were corroded by ruſt, and, independent of that circumſtance, had by far too much windage. And it is worthy of remark, that notwithſtanding this, the ſhells went farther than the ſolid ſhot before they met the ſurface of the earth or of the water, or had their firſt grazes greater when the gun was fired, either horizontally or point blank, or with any elevation not exceeding two degrees, but that with any elevation from two degrees upwards the ſolid ſhot went fartheſt.

The following is an exact ſtatement of experiments made at Languard fort on the 27th and 28th of July, 1780, by order of marquis Townſhend, then lord viſcount Townſhend, and maſter-general of the ordnance, and comparative trials with a ten and eight-inch howitzer.

*Practice with a 68 pounder carronade, or ſmaſher.*

The weight of the piece in cwt. qr. lb. 29 0 0.

The length of the piece in feet and inches, from the hind part of the baſe ring to the muzzle, 3 $11\frac{9}{10}$.

The length of the bore, chamber included, 3 11.

The diameter of the bore, 8 inches.

The nature of the rope for breaching, 2½ inches.

The length of the recoil, in feet and inches, 12 3.

Weight of the ſolid ſhot, 68 lb.

Weight of the ſhell ſhot, 57 lb.

A 10 inch braſs howitzer, weighing 23 cwt. 3 qr. and 7 lb. fired horizontally, or point blank, with five pounds of powder, had its firſt graze at the diſtance of 112 yards, with one degree of elevation at 200 yards, with two degrees of elevation at 300 yards, and with three degrees of elevation at 414 yards.

When fired horizontally, or point blank, with ſix pounds of powder, it had its firſt graze at the diſtance of 80 yards, with one degree of elevation at 225 yards, with two degrees of elevation at 290 yards, and with three degrees of elevation at 445 yards.

An eight-inch braſs howitzer fired horizontally or point blank with two pounds of powder, had its firſt graze at the diſtance of 119 yards, with one degree of elevation at 195 yards, with two degrees of elevation at 200 yards, and with three degrees of elevation at 246 yards.

When fired horizontally or point blank with three pounds of powder, it had its firſt graze at the diſtance of 125 yards, with one degree of elevation at 208 yards, with two degrees of elevation at 278 yards, and with three degrees of elevation at 336 yards.

The recoil of the ten inch howitzer fired horizontally or point blank was 11 feet with 5 pounds of powder, and 13½ feet with 6 pounds of powder.

The recoil of the eight-inch howitzer fired horizontally or point blank with 2 pounds of powder was 10 feet, and with 3 pounds of powder 16 feet.

An iron 24 pounder, of the late lord Howe's conſtruction, fired with ſix pounds of powder and one degree of elevation, had its firſt graze, on a medium of four trials, at the diſtance of 471½ yards; and with five pounds of powder and the ſame elevation, on a medium of two trials, at 507½ yards.

A 32 pounder iron gun fired horizontally or point blank with high ſhot and four pounds of powder, had its firſt graze at the diſtance of 200 yards, with the ſame ſhot, charge, and one degree of elevation at 465 yards, and with two degrees of elevation at 675 yards.

And the ſame gun with the ſame charge, point blank, and the ſame elevations, but with low ſhot, gave the firſt grazes at 220, 395, and 662 yards reſpectively.

Theſe experiments clearly prove the great ſuperiority of the ſmaſher, or 68 pounder carronade, over not only the eight-inch howitzer of the ſame bore with it, but alſo over the ten-inch howitzer, which is the largeſt in our ſervice, and has its bore to that of the ſmaſher as 100 to 64, and the diameter thereof to that of the ſmaſher as 10 to 8.

They alſo ſhew, that it is nearly on a footing with the common iron 24 and 32 pounder, as to its firſt grazing diſtance, which is a material point in ſea-ſervice, and has greatly the advantage of them, particularly in cloſe combat, by the ſize of the holes which its ſhot make in the ſides of a ſhip, and from their likewiſe paſſing through the ſame with leſs velocity. For a ſhot, eſpecially if its diameter be but ſmall, that paſſes very quickly through a ſhip's ſide, makes only a clean hole, whereas one of a large diameter, that penetrates it with leſs celerity, makes a rough and ragged one, by tearing and ſplintering the planks and timbers. And it is well known that ſhot fired at ſea with a greater elevation than five degrees, are of no uſe whatever, unleſs they hit the object they are fired at before they meet the ſurface of the water, as they never graze or riſe again from it when fired with ſo great an elevation. It may be objected to the uſe of ſmaſhers on board a ſhip, that their ſhot are too heavy to be eaſily handled and put into the gun. This objection holds good againſt the uſe of them with their ſhot in its ſolid form, which of all others is the moſt unfit for ſea engagements. It vaniſhes, however, when it is conſidered that the weight of its ſhot may be reduced by leaving it hollow, or with a core in the centre, from 68 pounds down to 42 pounds and under, and ſtill retain thickneſs and ſtrength of metal enough for penetrating the ſide of any ſhip whatever. This fact has been eſtabliſhed beyond even the poſſibility of controverſy by ſome experiments that were made at Woolwich in 1781, in the preſence of general Melville who propoſed them, and his grace of Richmond, then maſter-general of the ordnance. For in July that year Mr. Gaſcoigne ſent from Carron to Woolwich for that purpoſe ſix hollow ſmaſher, or 68 pounder carronade ſhot, weighing from 55 pounds to 55½ pounds, ſix others reduced in weight from 68 to from 50 to 50½ pounds, ſix others weighing only from 45¼ pounds to about 46½, and ſix reduced down from 68 pounds ſo low as from about 43 pounds to 40. The lighteſt of theſe were fired into a bulk-head, as thick as the ſide of a firſt rate, from a ſuitable diſtance. They eaſily penetrated it, and one of them, after penetrating, ſtriking againſt an oak poſt or ſtud, nine inches ſquare, tore, ſhattered, and ſplintered it almoſt to pieces. The maſter-general, after viewing its effects, ſaid it would have been a terrible ſhot againſt a ſhip, and very juſtly obſerved, that as the lighteſt of theſe hollow ſhot were found to anſwer perfectly, it was unneceſſary to try the heavier ones. We are convinced, indeed, that the ſhot of a ſmaſher, or 68 pounder carronade might, by means of concentric cavities, be reduced down to the weight of 32 pounds, and ſtill retain ſtrength and thickneſs of metal ſufficient for penetrating the ſide of any ſhip. In this ſtate they would be much more eaſily handled than a common 32 pounder ſhot, having a larger diameter and a much larger ſurface. Theſe experiments ſhew, that they are ſufficiently ſtrong for that purpoſe when brought down to within eight pounds of that weight. And if, in addition to this fact, it be alſo taken into conſideration, that a multitude of experiments made with ſmaſhers, or 68 pounder carronades, concurred in eſtabliſhing this point, that when fired either point blank or with any elevation not exceeding two degrees, the hollow ſhot went farther than the ſolid ſhot before they met the ſurface either of the ground or water, it muſt readily be allowed, that they are peculiarly calculated for naval combats. But were theſe hollow ſhot to be fired as ſhells, with a ſufficiency of powder in their cavities for burſting them, they would be truly terrible and tremendous to ſhipping in a ſea-fight. It may be alleged, that the enemy would ſoon alſo get into the uſe of them as ſhells. It is true that after a time he might: but whoever ſhall make this uſe of them in a great naval action, he will certainly derive infinite advantages from it. And we truſt our enemies will not be the firſt to make ſuch an application of this very uſeful piece of ordnance.

*Of the poſition of the vent in cannon, and other pieces of ordnance.*

As the inflammation of fired gunpowder is almoſt inſtantaneous, it is natural to conclude, that the impulſive force of a given charge of it is not, *cæteris paribus*, ſenſibly altered by its being fired in any particular part or point of it; and of courſe, that neither the initial velocity nor range of a ball is ſenſibly affected by the poſition of the vent. This is a fact that has been ſufficiently eſtabliſhed by experiments made at Woolwich, by the learned Dr. Hutton, and ſeveral reſpectable officers of artillery, under the authority and direction of the board of ordnance.

The vent is vulgarly called the *touch-hole;* and is the narrow cylinder or opening through which fire is conveyed from the outſide of the piece to the powder that compoſes the charge.

Formerly both theoriſts and practitioners differed widely from one another in regard to the proper poſition of it. It has been cuſtomary to place it from one quarter of an inch to half an inch from the bottom of the chamber or bore, and ſometimes a whole inch. An idea prevailed, that if the vent were directly oppoſite to the middle of the charge, the powder would be inflamed in leſs time than in any other place, and that the exploſion would of conſequence produce a greater initial velocity and range. This erroneous concluſion was founded on the ſuppoſition that if a tube were filled with powder and lighted in the centre, the powder would be burnt in half the time that it would if lighted at either end, and on inadvertence to this circumſtance, that the inflammation of fired gunpowder is ſo nearly inſtantaneous, that no ſenſible difference as to the time in which it takes place can ariſe, from the firing of a charge in the centre in preference to any other part of it. In order to determine this point, Frederic the Great, or the Second, of Pruſſia, ordered a light three pounder to be caſt with three ſhifting vents, one at the centre of the charge, one at the bottom of the bore, and the other at an equal diſtance from the bottom and centre one; ſo that when one was uſed the other two might be ſtopped up. The gun weighed 2 cwt. 1 qr. 20 lb. Its length was three feet three inches, and the bottom of the bore, inſtead of being rounded, was quite flat. It was loaded each time with one quarter of the ſhot's weight of powder. It was found that when the loweſt or bottom-vent was uſed, the ranges were rather the greateſt, and that they were ſomewhat leſs as the vent was more and more diſtant from the bottom. The differences, however, were ſo ſmall, that they might very eaſily have been produced by the leaſt inaccuracy in making the experiments, or by the gun's being a little more heated at the time of making one than another, and but little reliance can be placed on them.

*On the form or figure of the chamber of a piece of ordnance.*

The chamber of a gun, mortar, or howitzer, is the cavity at the bottom of the bore, that receives the charge of powder, and communicates with the vent, through which the fire of the priming is communicated to the ſame. There are but few guns that have chambers, except ſome of the largeſt ſizes and calibers, as it has been found by experience, that they have ſcarce any ſenſible influence or effect on the velocity of the ſhot in ſmall and middle ſized ones.

Various have been the opinions of authors and artilleriſts reſpecting the forms or figures of chambers; and different nations have had them conſtructed very differently. The Spaniards have been in the practice of uſing chiefly the ſpherical chamber for their mortars; the French, Germans, and Dutch, the conic, cylindric, and the concave, or bottled, or the *chambre à poire*, or pear chamber. The Portugueſe have made uſe of the parabolic form, which was firſt ſuggeſted or invented by count de Lippe Buckeburg. And the Engliſh have been in the habit of making theirs in the form of a fruſtum of a cone.

The cylindric chamber is that which is equally large every where, or has the diameter of its bore in every place or part of it the ſame. This is found to be by far the moſt commodious form for great guns or cannon of a large caliber, and is indeed almoſt the only kind of chamber that is made uſe of in ſuch pieces of ordnance.

The ſpheric, or ſpherical chamber, as its very name imports, is that which is made in the form of a ſphere, or bullet, or at leaſt very nearly ſo. This ſort of chamber for guns, or cannon, was invented towards the cloſe of the ſeventeenth century. The object of this invention was to throw balls and ſhot with as much force from ſhort, light, and eaſily tranſportable cannon as that with which they were thrown from the long, cumberſome, and ponderous pieces then in uſe. It was found by experience, that the advantages expected and propoſed were obtained by this alteration in the interior arrangement of the bores of guns, or by the conſtruction of ſuch pieces. For though they were made a good deal ſhorter than thoſe formerly made uſe of, and were fired with a ſmaller quantity of powder, they produced the ſame effects. But as it was difficult to wipe, or clean out the interior cavities of ſuch chambers after the cannon were fired, ſome fire frequently remained in them, which ſometimes occaſioned the loſs of arms to the cannoniers, or the perſons who were employed to ſerve and manage them. Beſides theſe inconveniences, they were attended with others; for the inflamed powder, before it quitted the chamber, acted in all directions with ſuch force and impetuoſity, that their carriages were ſoon either broken or rendered unſerviceable. They recoiled very much and fired with little certainty. For theſe reaſons, guns with ſpherical chambers were totally laid aſide; and ſuch of them as were found in the arſenals and fortreſſes in France were caſt anew into cannon, having cylindric bores every where equal and alike. The guns commonly made uſe of at preſent have no chambers, except ſome of the largeſt calibers. And even theſe have their chambers cylindrical.

The very ingenious Mr. Robins in the ſcholium to the ninth propoſition in his new principles of gunnery aſſerts, that what ſome authors have advanced in regard to the advantages of having particular forms for the chambers of mortars and cannon, is altogether inconcluſive, and founded on erroneous conceptions of the action of fired gun-powder. The learned Mr. Euler, however, in his commentary and remarks on Mr. Robins's treatiſe, contends for the ſpherical chamber as the beſt. He admits that Mr. Robins's concluſion would be true did the inflammation of the powder take place in an inſtant. He allows, that the force of the powder on the ſuppoſition of its firing inſtantaneouſly would be the ſame, whatever be the form of the ſpace behind the ſhot or ſhell that contains it, and whether this ſpace be either wholly or only partly filled with it. He alſo allows, that its impelling power after the ball or ſhell is once in motion, will in this caſe be the ſame, as well as its firſt impulſive force, whatever be the form of the chamber; that if no better reaſon than the increaſing of the impelling force can be aſſigned for changing the figures of chambers, either in guns or mortars, from what they uſually are, all propoſals for altering them, except ſuch as tend to render them more convenient and commodious, ought to be rejected without further examination.

Leaning, however, towards an opinion of profeſſor Bernoulli, that the elaſtic force of the fluid generated by the exploſion of gunpowder, is nearly ten thouſand times greater than the preſſure of the atmoſphere, he ſuppoſes the inflammation of gunpowder to be gradual inſtead of being almoſt inſtantaneous, and therefore concludes, that chambers may be improved by changing their figures, and that the ſpherical form is the beſt of any, as being capable of holding the greateſt quantity of powder under the ſame circumference, as better calculated than any other for keeping the grains near, or contiguous to one another, and for quickening, or accelerating the exploſion. The experiments which he appeals to, and produces for eſtabliſhing this hypotheſis, are altogether inconcluſive, and muſt have been conducted with great inaccuracy, or inattention to ſome circumſtances that were connected with, and influenced them. They were made in preſence of him, Mr. Bernoulli, and ſeveral other members of the academy, at St. Peterſburg, by general Gunther in 1728. And from two of them he infers, that a ball fired vertically with eight ounces of powder from a piece, which had the length of its cylinder equal to $7\frac{7}{10}$ Engliſh feet, iſſued out of it with thrice the velocity which it iſſued with, fired with the ſame quantity of powder from the ſame piece, when the length of its cylinder was reduced to ſix feet, by ſawing one foot and ſeven-tenths of a foot off from it. Taking this inference too precipitately for granted, he obſerves, by way of proving the great inaccuracy of Mr. Robins's poſition, "that all the powder of the charge is fired and converted into an elaſtic fluid before the bullet is ſenſibly moved from its place;" that according to this theory, the velocity inſtead of being thrice as great would have differed from the other ſcarce perceptibly, and therefore moſt erroneouſly concludes, that the greateſt part of the powder muſt have fired whilſt the ball moved through the laſt foot and a half of the bore of the piece, before it was reduced in length. Now, the quadruplicate ratio of $7 + \frac{7}{10}$ to 6, or of 77 to 60, is that of 35,153,041 to 12,960,000, which is conſiderably leſs than the ratio of three to one. Mr. Euler then makes the velocities of the ſame, or equal ſhot fired with the ſame charge of powder from bores of the ſame diameter, but of unequal lengths in ratios to one another, reſpectively greater than the quadruplicate ratios of theſe lengths. We know, however, from experiments made with inconteſtable accuracy at Woolwich on Mr. Robins's plan improved, that theſe velocities are in ratios ſomewhat leſs than the ſubduplicate ratios of the lengths of the bore, but in ratios ſomewhat greater than the ſubtriplicate ratios of the ſame lengths, and nearly indeed in mean or middle ratios between the two. Mr. Euler's making the ratios of theſe velocities ten times as great as they really are, proves incontrovertibly both his theoretical reaſonings, and his experimental inferences againſt the poſition of the almoſt inſtantaneous firing of gunpowder, and in ſupport of the hypotheſis of its firing gradually in the way he deſcribes, to be completely erroneous.

The objections he endeavours to draw from rifled pieces againſt the truth of Mr. Robins's ſeventh propoſition, being inconſiſtent with facts and experiments, are likewiſe fallacious and inconcluſive.

A conic or conical chamber is that which is in the form of a fruſtum of a cone, with its bottom ſometimes circular, but generally hemiſpherical, or nearly ſo. We have been in the habit of uſing ſuch a form for chambers with the greateſt diameter of each at its mouth, or entrance, contrary to reaſon and principles, which point out the advantage and propriety of having the impulſe of the inflamed powder made on the ſhell or bullet as near to its axis, or to that of the bore of the piece as poſſible.

Count Buckeburg propoſed the parabolic form, or that of a paraboloid, or parabolic conoid, which has been made uſe of by the Portugueſe as the beſt, erroneouſly ſuppoſing, that were the fire introduced to the focus, the rays of lighted powder would by the nature of the figure be reflected into parallel directions like the rays of light.

A concave chamber is that which has its mouth or entrance narrower than its inſide cavity. It may be ſpherical, ſpheroidal, in the form of a pear, called by the French, une chambre a poire, in the ſhape of an egg, of a bottle, and a variety of other forms.

Much more, however, depends on the entrance of the chamber, than on its form or figure. The entrance ought to be directly oppoſite to the middle of the ball, or ſhell, and to have no greater width than what is neceſſary for cleaning out the chamber, which ſhould contain no more powder than the greateſt charge proper for ſervice, to prevent as much as poſſible any vacancies being left between it and the ſhell or bullet. As the cylindric is the moſt convenient form for being eaſily cleaned out, it ought to be preferred to others on account of its ſimplicity. For, in moſt of the affairs of life, and more eſpecially in thoſe of war, of all things of the ſame kind, the ſimpleſt are the moſt commodious.

### *Of the poſition of the charge of powder.*

Every experiment that has been made reſpecting the poſition of the charge of powder, proves the advantage of its lying cloſe to the ball or ſhell. Among others, the following are well deſerving of notice.

The ingenious general Deſaguliers in 1753, and Mr. Muller, then profeſſor of fortification in the Royal Military Academy at Woolwich, made a number, repeatedly with a ſmall mortar, which had ſeveral ſhifting chambers.

Into a narrow cylindric chamber of about four inches long, and holding about twelve grains of powder, there was put a thin cartridge filled with ſix grains. This cartridge was placed in the chamber in ſuch a manner as to lie cloſe to the ſhell, leaving a vacuity or empty ſpace between it and the bottom of the chamber, and was fired by means of a quick match, introduced through the vent. A cartridge of the ſame ſize, and containing the ſame quantity of powder, was then put into the ſame chamber, but placed at the bottom of it, leaving an empty ſpace between the powder and the ſhell, and was fired in like manner. Laſtly, an equal cartridge with the ſame charge of powder was placed in the middle of the ſame chamber, or equally diſtant from the bottom thereof and from the ſhell, and was fired in the ſame way. Theſe experiments were frequently repeated, and it was found, on every repetition of them, that in the firſt caſe, the ſhell was thrown nearly twice as far as in the ſecond, and that the diſtance it went to in the third caſe, was about an arithmetical mean between its ranges in the firſt and ſecond.

They alſo found, that when the ſame quantity of powder was put looſe into the ſame mortar, and a piece of writing paper laid on it, the ſhell was thrown conſiderably farther than it was by the ſame charge of looſe powder without the paper.

They likewiſe found, that three cylindric ſhifting chambers of different lengths, but holding the ſame quantity of powder, produced, when filled, equal ranges, but that when they were not quite filled, the longeſt gave the greateſt range.

They alſo tried ſome experiments with two chambers in the form of a fruſtum of a cone, one of which had its largeſt diameter at the bottom, and the ſmalleſt at the entrance, and the other its ſmalleſt diameter at the bottom and the largeſt at the entrance, and always found, that the firſt of theſe with the ſame charge of powder, threw the ſhell farther than the ſecond.

General Deſaguliers alſo found by experiments, that grained and mealed powder were about equally ſtrong when in good order and condition ; but on putting a ſmall phial filled with water into the chamber amongſt the powder, he obſerved the ſtrength of the charge to be conſiderably increaſed.

### *Of the Windage.*

The windage of a gun, mortar, or howitzer, is the difference between the diameter of the bore and the diameter of the ſhot or ſhell. We have been in the practice and ſtill are, of making it equal to a twentieth part of the diameter of the ſhot in every gun except the carronades. The Dutch have commonly made their windage nearly the ſame as ours. The French have been in the habit of making theirs a twenty-ſixth part of the diameter of the ſhot. And the Pruſſians make the diameter of the bore of the gun to the diameter of the ſhot as 25 to 24. This is a moſt convenient proportion. But it makes the windage much greater than it ought to be. There ſeems to be no very good reaſon, indeed, for making the windage bear any given or determinate ratio to the diameter of the ſhot, ſince if the bores be true, the ſame windage that anſwers for a ſmall ſhot will be ſufficient, or nearly ſo, for a large one. The ſmaller the windage, the greater and truer will be the flight of the ſhot or ſhells ; for when it is great, they are apt to injure the bore by bouncing from ſide to ſide, and alſo, at leaving it, to receive from this kind of motion a ſort of cant or deflection from the line of their direction. With our preſent windage for guns, except carronades, from one fourth to one half of the charge is loſt and rendered uſeleſs. Short guns, indeed, with ſmall charges of powder and a very ſmall degree of windage will be more uſeful and ſerviceable than guns twice as long with double charges of powder and a large windage. We will not undertake to determine preciſely what the windage ought to be. But we are inclined to think, that if the ſhot and ſhells be caſt in moulds having exactly the diameters of the bores of the different pieces of ordnances for which they are intended, the retreat or ſhrinking of the metal in cooling, will for both leave a ſufficiency of windage. The windage we have been in the practice of allowing for ſhells of all ſizes, is a quarter of an inch, which is prepoſterouſly large and beyond all due proportion. Were it reduced even to a third or fourth part of that quantity it would be ſufficient.

In our common 12 pounder, 18 pounder, 24 pounder, 32 pounder, and 42 pounder, there is allowed reſpectively a windage of 0.22 inches; 0.252 inches; 0.277 inches; 0.305 inches; and 0.334 inches. But in our 12 pounder, 18 pounder, 24 pounder, 32 pounder, and 42 pounder carronades, the windage is only about 0.097 inches; 0.1 inches; 0.123 inches; 0.145 inches; and 0.166 inches reſpectively, which gives them a great advantage and ſaves much powder.

*Of the caſting and boring of cannon.*

The caſting of a gun in its ſtrict and limited ſenſe is, the running of any ſort of metal or mixture of metals, of which the gun is intended to conſiſt or be compoſed, into a mould prepared for receiving the ſame, and having its inſide of ſuch a ſhape, as to form the outſide of the gun. But the caſting of cannon in its more general acceptation, includes every thing, and operation preparatory to, neceſſary for, and connected with the founding of them, ſuch as the making of the models, moulds, &c. &c. for all which ſee the article FOUNDERY.

Cannon, as we have already obſerved, were originally made of bars of iron fitted together lengthwiſe, or of ſheets of iron rolled up and faſtened together, and hooped with iron rings. They were ponderous, clumſy, cumbrous, in a great meaſure unmanageable, and could not be tranſported from one place to another but with great difficulty and labour. They were chiefly employed for throwing large ſtones like the machines of the ancients, which they ſucceeded. Theſe were gradually ſupplanted by braſs cannon, which had much ſmaller calibers, and threw iron bullets inſtead of ſtones, but produced in a few hours greater effects than the others could in many days. Theſe guns were firſt caſt of a mixture of copper and tin, called gun-metal from that circumſtance, which continued to be employed for that purpoſe for a long time before caſt iron was made uſe of. In the courſe of time, however, as the uſe of artillery became more general, and the number of cannon greatly increaſed, iron guns were invented by way of leſſening the expence. An idea, however, that prevailed of their being very liable to burſt when much heated by firing, retarded the general introduction of them into ſervice, and was the cauſe of their being made much heavier than braſs guns of the ſame calibers. And this apprehenſion ſtrengthened by ſome accidents of the kind that took place either through improper management, or the careleſſneſs and unſkilfulneſs of ſome founders, has militated againſt the general uſe of them even down to the preſent time. When caſt, however, with iron obtained from good virgin ore, to which the founders can give any degree almoſt of malleability, of which the Carron company and others have afforded many proofs and ſpecimens, they reſiſt burſting as much as braſs cannon, and poſſeſs great advantages over them, as theſe are compoſed of ingredients, that melt with different degrees of heat, and are thereby not only liable to be ſoon injured when much heated, but alſo to be rendered in a ſhort time totally unſerviceable by quick and continued firing.

Till about 40 years ago, cannons were caſt with a cylindric cavity in each of them, having nearly the ſame diameter with the intended caliber of the piece, which was afterwards enlarged to the proper ſize by machines, one of theſe is repreſented. See *Cannon, fig.* 13. Two caſt iron bars, A A, were confined in a vertical poſition, by being ſcrewed to the four beams, B, B, B, B; between theſe bars a caſt-iron frame, C C, was at liberty to ſlide; to which frame the gun, D D, was fixed by a band, *c*, acroſs the baſe ring, fixed by two ſcrews, another ſimilar band, *e*, fixed acroſs the chace, and two ſmaller ones, *a a*, ſcrewed acroſs the trunnions, to prevent the piece from turning round by the action of the drill-bar, E; a tin or copper pan, F, was fixed on the drill-bar for containing the chips of metal ſeparated from the piece by the borer on the top of the drill-bar. After the gun was prepared by boring, by cutting off the cap or piece of metal left at the muzzle with a ſaw, it was brought under the frame, C C. The two blocks of pulleys, G G, were unhooked from the frame (which was let down and reſted on the bottom of the bars A A), let down and faſtened to the gun below, by chains, to hoiſt it up into the frame, C C, where it was fixed by the ſcrews; the pulleys were then hooked into the top of the frame, to raiſe it with the gun, high enough to introduce the borer; the pulleys were afterwards ſlackened, and the drill-bar, which worked in a ſocket in the ground, ſet in motion by horſes or otherwiſe, the gun being kept to the work by its own weight; when the gun was bored far enough, it was prevented from deſcending any farther by the block, H, which was adjuſtable by ſcrews, to the proper length of the bore; when the piece was bored, the pullies were again uſed to ſupport it, while it was detached from the frame, and afterwards to lower it down.

Owing to the unequal contraction of the metal between the core and the outſide of the mould, guns caſt hollow were always more or leſs ſpongy, and numberleſs cavities were formed round the core, ſome of which were too deep for the borer to cut out; this and other reaſons have occaſioned the old method to be laid aſide, and guns are now univerſally caſt ſolid. The old machines alſo, where the gun was fixed, not being found to bore always in the right direction, ſeveral new machines have been ſubſtituted, ſome of which are repreſented in *figs.* 14, 15, 16 and 17.

*Fig.* 14. is a machine uſed at the *Garratt Iron Works*. In this, contrary to the former one, the gun, B, is turned by the ſhaft, A, moved by a water-wheel; the drill-bar, E, is advanced by a weight, C, acting on a bent lever, whoſe fulcrum is F; when the weight, C, has deſcended to the floor, or nearly, it muſt be lifted up, and the point, G, then acting as a fulcrum, the rod, H, will be drawn forwards, one or two teeth of the rack, I, and the weight will be ready to act again as before. The gun, B, is fixed by a ſquare lump caſt on the end of the caſcable, into a coupling box, and wedged up, and the chace of the gun moves in a collar. The only guns caſt at theſe works are carronades.

In *fig.* 15. the gun is fixed in the ſame manner as *figs.* 14 and 17, except that the box, K, is fitted by ſcrews inſtead of wedges, the drill-bar, E, reſts on a block, F, juſt before it enters the gun, and the other end is fixed to a carriage, G, moving on wheels, *a a*, to diminiſh friction; to the bottom of the carriage, a rack, I, is fixed, working into a pinion, L, the rack is kept to the pinion by a roller, *b*; on the end of the axis of the pinion a capſtan-head is fixed, with mortiſe-holes in it, to contain one end of an iron bar, *d*, while the other is loaded with a weight, C, for advancing the borer, and is ſhifted into a freſh hole as often as the weight deſcends to the ground.

In the machine, *fig.* 16. the muzzle of the gun can be elevated or depreſſed, to ſuit guns of different bores, by ſcrews, *c*, between the two plates, *a b*; the plates can alſo be moved farther from or nearer to the coupling box, by a ſcrew, *d*, to ſuit guns of different lengths; the two blocks, F G, between which the rack, I, is faſtened, are fixed down to the beams, A, B; the pinion, L, is faſtened to the block, M, which can ſlide between the beams, A, B, and has wheels above and below the beams, to diminiſh the friction; to this block, one end of the drill-bar, E, is fixed; near the other, it reſts on the block, F; on the end of the axis of the pinion is a wheel, *f*, with teeth parallel to its axis, on the end of which axis the bar, *g*, is looſely fitted; to the other end of the bar the weight, *c*, is hung; when the weight is down, the bar muſt be ſlid along the axis, far enough to be lifted up clear of the teeth, and is to be puſhed back into its place again, above the next tooth.

The machine at the *Royal Arſenal* at Woolwich is ſhewn in *fig.* 17. The two ſupports of the gun, A B, are of ſolid braſs, and well poliſhed; the drill-bar, E, ſlides on a ſtrong table, with the rack, I, at its end, the axis of the pinion, *o*, is upright, and has a wheel, *d*, at its top, working into an endleſs ſcrew, *e*, which has a wheel, *f*, upon the end of the ſpindle, with handles on its circumference, for two men to turn it round by; on one of the ſpokes, *g*, a common handle is fixed, to turn the wheel back, for withdrawing the drill-bar; the pinion, endleſs ſcrew, and wheel, *d*, are incloſed in a braſs box, which ſupports their axes. We think this machine might be improved, by having the pinion horizontal, and applying a weight to it, as before deſcribed in the other machines.

Cannons are always caſt with a large cap, or piece of ſpare metal, at the mouth; in the old guns, which were caſt hollow, this piece was cut off by a ſaw; in the ſolid guns, at the Garrat iron works, it is cut off by a machine, repreſented in *fig.* 20. On the lathe for turning the outſide of the gun, a caſt-iron frame, A A, is fixed, for ſupporting ſteadily the chiſel, *b*; between the end of the chiſel and the frame, a wedge, *d*, is put in, which a man continually drives with a hammer, to advance the chiſel, and turn a notch in the gun; when it is cut about 1½ inch deep, it is broken off by hammers. We think a ſcrew would be judiciouſly ſubſtituted for the wedge.

After cannons are bored, and their outſides turned, the touch-holes are drilled by inſtruments, *figs.* 18 and 19.; in *fig.* 18. A A A is a frame of wood, mounted on wheels, B, at one end, for convenience of moving when it is to be uſed; the frame is wheeled cloſe to the gun, D, laid on two blocks of wood, F F, high enough to take the wheels off the ground, and prevent its running back; the drill, E, and its bow, G, are then to be fixed, between the place of the touch-hole of the gun and the block, H; which block is advanced by one arm, I, of a bent lever, by means of the weight, C, hung on the other arm, *d*.

In *fig.* 19. A is a beam of the building, through which a ſcrew, B, works; the lower end of this ſcrew is hollow for ſome inches, to receive a ſmall part, *c*, of the drill, C; on the lower end of the drill a leaden wheel, F, is fixed, to act as a fly; to the upper part, *c*, of the drill, the ends of two ſtrong catguts are faſtened, and after being twiſted round it a few times, the other ends are tied to a handle, E E, at *e* and *f*. To uſe this machine, a gun is brought and laid under the beam, A, the drill ſet up with the point, *c*, in the end of the ſcrew, B, which muſt be ſcrewed down till the point, *c*, touches the bottom of the hole in the ſcrew, to prevent the point of the drill from ſlipping away from the intended touch-hole; the workman muſt then wind up the cords, by turning the wheel, F; when the handle, E, is in the poſition of the figure, he muſt force it down quickly, which will turn the drill round; when the catguts are untwiſted, he muſt let the handle riſe, but ſtill hold it, to prevent its turning round with the drill, which will continue to turn by the momentum of the wheel, F, and wind the handle, E, to the ſame height as in the figure, but with the cords in a contrary direction. The man muſt then force the handle down again as before.

*Fig.* 21. repreſents the different kinds of borers; A is the borer uſed for ſolid guns, and *a* a ſection of the ſame; B and C are different views of the borer for boring hollow guns the firſt time, and D and E are two different borers for finiſhing either kind of guns.

The following are the dimenſions, both of the iron and braſs guns, which the French uſe at preſent in their ſea and land ſervice, and have made uſe of ever ſince their revolution.

Table of the dimenſions of French iron cannon for ſea ſervice taken parallel to their axes.

*Canon a l'Eſpagnole*, or a Spaniſh cannon, is one, that has a chamber at the bottom of the bore in the form of a ſphere or a little flattened.

*Canon a la Suedoiſe*, or a Swediſh cannon, is a piece, that carries a four pound ball, and weighs about 600 lbs.

*Canon de Campagne ou de bataille*, field or battle-cannon, are pieces that are employed in the field with armies.

The compoſition and proportions of the ingredients made uſe of in caſting braſs cannon, are nearly the ſame in the different nations in Europe. Founders have affected to keep this compoſition a ſecret: it is, however, well known: and if it were not, it would be a ſecret not worth keeping. For none of them have been able to find out a compoſition for ſuch guns, as will enable them to ſtand quick and continued firing, or a hot engagement, without either melting or becoming uſeleſs. They are not ſo well calculated for ſevere and hard ſervices as good iron guns, that are both lighter and more tranſportable.

The common proportion of the copper to the tin in gun-metal, is that of 100 to 12. Some founders put to 240 lbs. of metal fit for caſting 68 lbs. of copper, 52 lbs. of braſs, and 12 lbs. of tin. The Germans put to 4200 lbs. of metal fit for caſting, $3687\frac{33}{41}$ lbs. of copper, $204\frac{13}{41}$ lbs. of braſs, and $307\frac{30}{41}$ lbs. of tin. Some uſe 100 lbs. of copper, 6 lbs. of braſs, and 9 lbs. of tin; and others 100 lbs. of copper, 10 lbs. of braſs, and 15 lbs. of tin. In ſhort, different founders are guided in their proportions of theſe materials, by their own whims and fancies. See Copper.

The French make uſe of mortars, that have their calibers, or the diameters of their bores, each equal to eight inches, three lines of their meaſure. Theſe mortars have cylindric chambers, each of which contains $1\frac{3}{4}$ lbs. of powder. Such a mortar weighs 500 lbs.

They have alſo mortars of twelve inches diameter with cylindric chambers, each of which contains five pounds and a half of powder. Such a mortar weighs 1450 lbs.

They have likewiſe mortars of twelve inches caliber, or diameters with chambers *a poire*, or pear chambers; each of which holds, in like manner, five pounds and a half of powder. Such a mortar weighs 1700 lbs.

They uſe alſo mortars of twelve inches caliber, or diameter with pear chambers, each of which holds twelve pounds of powder. Such a mortar weighs 2300 lbs.

Beſides theſe, they have ſome of ſix inches diameter, and ſome of eighteen inches diameter or caliber.

They likewiſe uſe ſtone mortars, or mortars for throwing ſtones of fifteen inches diameter, with chambers in the form of truncated cones, each of which holds two pounds and a half of powder. Such a mortar weighs 1000 lbs.

Cannon, *ſhip*, are ſtronger in metal than thoſe uſed by land, on account of the neceſſity they are often under of being charged with chain-ſhot. They lie on ſhip-carriages, having four ſmall wheels, without ſpokes, with two ropes to ſtop their running back, and bring them again to their place upon the battery.

Cannon *of courſe*, or *Chace*-Cannon, in a galley, is the largeſt, middlemoſt, and moſt effective of the guns placed in the prow, or chace of the veſſel, and which delivers its ſhot over the very ſtem, generally carrying a ſhot of 33 or 34 pounds weight. It is a long piece, and recoils all along the middle of the galley to the maſt.

Cannon-*mouth of a bit*, in the *Manege*, denotes a round, long piece of iron, ſometimes compoſed of two pieces coupled together and bent in the middle. Cannon-mouths are contrived to keep a horſe in ſubjection, being ſo ordered that they riſe gradually toward the middle and aſcend toward the palate, that the void ſpace left underneath may afford a liberty to the tongue. See Bit.

CANNONADE. To cannonade any object either by ſea or land is to diſcharge or fire cannon at it. A cannonade may take place between fleets, ſhipping, armies, &c. It may be made by ſhips againſt ſhips, towns, works, batteries; or by batteries, works, towns, againſt ſhips, &c. A cannonade may take place between two armies, either occupying field poſitions, or drawn up in order of battle for the purpoſe of engaging. An army ſtanding on the defenſive may keep up a heavy cannonade on the enemy advancing to attack them. The beſiegers may cannonade the works of the beſieged, and the beſieged may cannonade the approaches and batteries thrown up by the beſiegers.

CANNONEER, or Cannonier, a perſon who is employed in the management, or in the working and firing of cannon. It is a term ſometimes made uſe of to denote an artillery-man, a gunner, and ſometimes an artillery officer. Thus, maitre canonier ſignifies an officer of artillery, whoſe duty it is to attend to the pointing, loading, and firing of the cannon in his charge.

CANNULA, in *Surgery*, is a hollow inſtrument, uſually cylindrical, and made of metal; employed for the tranſmiſſion of any fluid out of the body, or for the conveyance of ſome remedial application to an interior organ. For example, the ancients reſorted to ſuch an inſtrument, to defend the adjacent parts, on ſeveral occaſions, when they applied a hot iron ſo as to act as a cautery, (See Cautery); and the moderns employ a cannula to draw off pus or dropſical accumulation from within a large cavity, (ſee Dropsy, and Trocar): but the uſe of a cannula for keeping open deep wounds is very problematical; or rather, it is now generally rejected, as being hurtful in many caſes, and needleſs in all.

Cannula, or Canola, in *Eccleſiaſtical Writers*, was a tube of ſilver, or other metal, wherein were put the relics, which the pope ſent as preſents to princes, &c.

Cannula, or Canola, was alſo a ſort of ſiphon, through which they anciently ſucked the wine in the euchariſt.

CANO, Alonso, in *Biography*, called the Michael Angelo of Spain, from his excelling in the three arts of painting, ſculpture, and architecture, was born in 1600 at the city of Grenada. Having ſtudied the principles of architecture under his father, an eminent architect of his native city, he directed his attention to ſculpture, as a diſciple of Pacheco of Seville, and he afterwards applied himſelf to the art of painting in the academy of Juan del Caſtillo the painter, in the ſame city. Beſides many fine pieces which he executed for the public edifices of Seville, he alſo practiſed ſculpture, and made two coloſſal figures of St. Peter and St. Paul of ſuch peculiar excellence, that the Flemiſh artiſts are ſaid to have viſited Seville in order to have an opportunity of copying them. Claiming noble birth, and poſſeſſing a high ſpirit, his firſt productions were gratuitous. In conſequence of a quarrel with Sebaſtian de Llanos, an eminent painter, which terminated in a duel, he was obliged to quit Seville; and in the ſuite of the count-duke Olivares, as well as under his protection, he went to Madrid, where he was ſoon appointed firſt royal architect, king's painter, and inſtructor to the prince, Don Balthazar Carlos. In this ſituation he acquired diſtinguiſhed reputation as an architect, ſculptor, and painter. His fame, however, excited jealouſy and envy, and he was charged with plagiariſm in the compoſition of his pieces. But another circumſtance occurred, which was much more injurious to his proſperity. Upon his returning home one evening, he found his wife murdered and his houſe pillaged, and an Italian journeyman miſſing. The magiſtrates, diſcovering that Cano had been jealous of this Italian, and that he was attached to another woman, charged him with the murder; and he was reduced to the neceſſity of making a ſpeedy eſcape. He fled for refuge to Valencia, but was ſoon betrayed by the practice of his art; and he then ſought an aſylum in a Carthuſian convent near that city; and being deterred from taking the order by the dread of its auſterities, he returned to Madrid, where he was apprehended and delivered to the torture in order to extort a confeſſion. Having endured the rack without ſelf-crimination, he was again taken into favour by the king; and with a view to his future ſecurity, he obtained the clerical office of reſidentiary of Grenada. In this ſituation he enriched the churches of Grenada and Malaga with many paintings and ſculptures. But having been refuſed the payment of 100 piſtoles by a counſellor of Grenada for an image of St. Anthony of Padua, he daſhed the ſaint in pieces on the floor of his academy. This ſally of paſſion induced the chapter of Grenada to ſuſpend him from his function; but he was reſtored by the king, on the condition of finiſhing a magnificent crucifix, which the king had beſpoken, but which he had long neglected. From this time he led a life of charity and devotion; and when deſtitute of money, he ſupplied the wants of a beggar by ſketching a drawing upon paper, and directing him how to diſpoſe of it. The violence of his temper was ſtill unſubdued; and even in his laſt moments he could not be prevailed upon to make uſe of a crucifix which was preſented to him for adoration, becauſe it was ſuch a wretched piece of work, that he could not bear the ſight of it. Cano died at the age of 76, in the year 1676. Cumberland's Annals of Eminent Painters in Spain. Gen. Biog.

Cano, or Canus, John Sebastian del, a native of Biſcay, who accompanied Magellan in his voyage through the ſtraits, bearing his name, and who, after his death, took the command and proceeded to the iſles of Sunda. Thence doubling the cape of Good Hope, he arrived at Seville in 1522, having performed the voyage round the world in three years and four months. Charles V. gave him for a device a terreſtrial globe, with this legend, "Primus me circumdediſti," i. e. thou firſt haſt ſurrounded me. Moreri. Gen. Biog.

Cano, or Canus, Melchior, a Spaniſh theologian, was a native of Tarançon in the dioceſe of Toledo. Having ſtudied at Salamanca under Francis Victoria, and entered into the order of St. Dominic, he ſucceeded his preceptor in the theological chair in 1546. Between Cano and Bartholomew Caranza, archbiſhop of Toledo, who was alſo at the ſame time profeſſor at Salamanca, there ſubſiſted a jealouſy, which produced two parties in the univerſity. But Cano was ſuperior to his rival in the powers of his genius and the extent of his learning, as well as in the vivacity of his temper and the readineſs of his eloquence. Paul III. deputed him to attend the council of Trent, and in 1552 he was made biſhop of the Canary iſlands. He was diſtinguiſhed, by the favour of king Philip II. and of his unfortunate ſon, Don Carlos, and it is ſaid that he ſacrificed the intereſt of the latter to that of the former. He is alſo charged with having attempted to perſuade the king that he might lawfully make war againſt any ſovereign, in the aſſertion of his own rights; but in advancing this principle, he offended the court of Rome. Such were his ambitious views, that he reſigned his biſhopric in order to be near the court; but he could not long indulge them, as he died at Toledo in 1560, ſoon after he was appointed provincial of Caſtile. His work entitled "Locorum Theologicorum lib. xii." in which he explains the principles or ſources (for that is the ſenſe in which he uſes the term *loci*) whence arguments may be deduced for the confirmation of doctrines and opinions, is highly commended by Du Pin. Whilſt he maintains the authority of the church of Rome, and the infallibility of the pope, he introduces many liberal ſentiments, and it appears that he gave little credit to the legends and forgeries of corrupt ages. We have ſome bold and generous remarks to this purpoſe, cited by Dr. Jortin, in his "Remarks on Eccleſiaſtical Hiſtory," vol. ii. p. 316—319. Cano's Latin ſtyle is good. Beſides the work already mentioned, he alſo wrote "On the Sacraments," and "Six Lectures concerning Penance." Du Pin. Moreri.

Cano, or Ghana, in *Geography*. See Ghana.

Cano, a river of Finland, which paſſes by Biorneborg.

Canoa, a town of Japan, in the province of Iwami.

Canobio, a town of Italy, in the Milaneſe, on the weſt ſide of the lake Maggiore; 13 miles E.S.E. of Domo d'Oſcello. N. Lat. 45° 55'. E. long. 8° 47'

CANOE island, an iſland ſo called by Mr. Mackenzie in his voyage through the N.W. continent of America; ſituate in about N. lat. 53° 31'. W. long. 122° 48'.

Canoe-*ridge*, a rugged mountain of America, about 200 miles W. of Philadelphia, forming the eaſtern boundary of Bald Eagle valley.

Canoe, in *Sea Language*, a ſmall veſſel uſed by various inhabitants of the earth for the purpoſe of fiſhing, of trading, and travelling along rivers, and of war. Canoes are made of different materials, ſuch as the trunk of a tree, the bark of trees, ſkins of animals, &c. Canoes uſed on the American, or other rivers, in conſequence of the curved form of their tranſverſe ſection, carry their lading higher than ſquare-ſectioned boats of ſimilar width; and are therefore capable of conveying large hogſheads of tobacco, or of other articles, with ſafety.

Canoe *of the aborigines of Canada*, is made of the bark of the birch; and ſome are of a ſize ſufficient to contain four or five perſons.

Canoe *of the Eſquimaux*, is made of whalebone, about an inch ſquare; theſe are not ſet like ribs, but are from ſtem to ſtern faſt ſewed to each other with ſtrong ſinews, and covered over with ſeal ſkins. They are from ten to twenty feet long, and about two feet broad; they are formed like a weaver's ſhuttle, ſharp at both ends, ſo that they can be rowed either way. In the middle of the canoe are the ribs, both to keep the ſides aſunder, and to form the hole in the covering wherein the rower ſits. A flat hoop is fitted to this hole, riſing about four inches, to which the ſurrounding ſkin is ſewed. The Indian's ſeal-ſkin jacket, being of a proper length, he can occaſionally bend the ſkirt of it round the outſide of this hoop; by which means, he keeps the canoe free from water, and is enabled to procure his game far from the land, or in ſtormy ſeas. His paddle is from ſix to ten feet long, being light, and flat at each end: this ſerves him to balance and ſteer his canoe, but particularly to row it, which he does with that incredible celerity, that an Engliſh boat with ten oars is not able to keep company with the canoe. The young men in their exerciſe are taught to overſet their canoes, and when the bottom is upward, to recover by the dextrous management of their paddle, their former upright poſition, the men riſing again either on the ſide by which they went down, or on the contrary, as they pleaſe. The conſtruction of this extraordinary little veſſel, ſo admirably well adapted to the purpoſes of its owner, does the greateſt credit to the ingenuity of the conſtructors. There is a canoe of this deſcription in the repoſitory of the Royal Society, and another in the library of the mariſchal college, Aberdeen.

Canoe *of Davis Straights*, is in the form of a barge, ſeven or eight feet long, and two in breadth ; the materials made uſe of are pliant, bent and interlaced like an hurdle, and covered with the ſkins of ſea dogs, or wolves. This light boat carries only one man, who, ſeated in a hole formed in the middle of what, from this circumſtance, appears to be a deck, is enabled to fiſh, or to tranſport himſelf with facility, and without much apparent danger, from one coaſt to another.

Canoe *of the coaſt of Guinea*, is made by hollowing the trunk of a tree ; it is of a long figure, and ſwims with only a ſmall part of its body above the ſurface of the water ; ſo that the perſon who ſits behind, and guides the canoe, is frequently half covered with water. The breadth is no more than ſufficient to contain one man, and the length for ſeven or eight. The men are ſeated on round pieces of wood, and half their bodies are below the gunwale. Each man has an oar of a very hard wood, and all row together, like galley-men, in one concordant motion ; or, if an individual pulls too ſtrongly, putting the canoe out of its line, his miſtake is ſo well counteracted by the man that guides in the ſtern, that the whole ſeems to fly along the ſurface of the water, and cannot be long followed by any European veſſel. When, on the other hand, the ſea is high, they are unable to ſteer, the loftineſs of the waves preventing their anſwering the helm. When the ſurf overſets them, they have the addreſs to turn their canoe in the water, to empty it, and reimbark, without running the ſmalleſt danger, ſwimming all the time like fiſh. Theſe canoes are generally about ſixteen feet long, and one or two broad : there are, however, ſome much larger, meaſuring thirty five feet in length, five in breadth, and three in depth ; they are flat at the ſtern, with a rudder and deck ; the ſails are made of reeds, or of graſs. The canoes are not allowed to remain in the water, but are drawn on ſhore, and placed on four treſſels ; when dry, two men can carry a canoe on their ſhoulders. In ſhaping and hollowing the trunks they have felled, the negroes now make uſe of the hatchets that are ſold to them by the Europeans. They narrow them towards the bottom, and cut each end to a point, giving it a ſmall beak of about a foot long, and of a thickneſs adapted to the hand, for the purpoſe of lifting the canoe.

Canoe *of the Indian* and *Charibbee*, is the ſimple trunk of a tree, hewn on the outſide to the deſired form, and hollowed within by means of fire. Its ſize conſequently depends upon that of the tree of which it is made. It is rowed with paddles and oars, and ſometimes has the aſſiſtance of a little ſail. The lading is placed at the bottom, but as the canoe is not ballaſted, it frequently overſets. The aftermoſt oars ſupply the purpoſe of a rudder.

Canoe *of Nootka Sound.* The large war canoe is generally finiſhed on the ſpot where the tree grows of which it is made, and then dragged to the water-ſide. Some of them have been ſeen which were fifty three feet in length, and eight feet in breadth. The middle part of theſe canoes is the broadeſt, and gradually narrows to a point at each end; but their head or prow is generally much higher than the ſtern. As their bottoms are rounded, and their ſides flam out, they have conſequently ſufficient bearing, and a conſiderable degree of ſtability. They have no ſeats, but ſeveral pieces of wood, about three inches in diameter, are fixed acroſs them to keep their ſides firm, and preſerve them from being warped. The rowers generally ſit on their hams, but ſometimes they make uſe of a kind of ſmall ſtool, which is a great relief to them. In the act of embarking they are extremely cautious, each man regularly taking the ſtation to which he has been accuſtomed. Some of theſe canoes are poliſhed and painted, or curiouſly ſtudded with human teeth, particularly on the ſtern and prow. This is affirmed on the authority of captain Cook, who ſays that the people of the ſea coaſt adorned their canoes with human teeth. But Mr. Mackenzie (Journal of a Voyage through the N.W. Continent of America, p. 335.) informs us, that he was particular in his inquiries, and that he obtained the moſt ſatisfactory proof that captain Cook was miſtaken ; and that his miſtake aroſe from the great reſemblance there is between human teeth and thoſe of the ſea otter, with which the gunwale, fore and aft, of a canoe, which he examined, was inlaid. The ſides were ſometimes adorned with the figure of a dragon with a long tail, of much the ſame form as is ſeen on the porcelain of China, and in the fanciful paintings of other countries.

Canoe *of Ruſſia*, employed on the lake of Wolda, is rounded at both ends ; it is much wider in the middle than at either end, and is worked with a ſingle oar, which is placed at the ſtern : but all the other canoes of that country terminating ſharply both ways, are elevated before as well as behind. They are hardened by means of fire, protected from the weather by paint, and laſhed round for the purpoſe of giving them additional ſtrength.

Canoe *of Terra-del-Fuego* and the *Straights of Magellan*, is of a peculiar conſtruction. The natives take the bark of the largeſt trees, and bend it into a ſhape with ſo much ſkill, that the veſſels have a reſemblance to the gondolas of Venice. For this purpoſe they place it on a ſmall piece of wood, as Europeans place a ſhip on the ſtocks ; and when the bark has taken the gondola form, and the neceſſary bend, they line the bottom and ſides, from one end to the other, with upright pieces of their wood, in the ſame manner as the parts or frames of a ſhip are put together : round the top of the deck another bandage of bark is drawn, in doing which, the utmoſt care is taken to faſten the whole together. Theſe canoes are from ten to ſixteen feet in length, and two in breadth ; holding with ſufficient convenience, ſeven or eight men, who row ſtanding, and with extreme celerity. See alſo the articles boat, proa, &c.

CANOGE, or Canouge, in *Geography*, a town of Hindooſtan, ſeated on the right bank of the Ganges, near the place where the Calini or Callynuddi river joins it. Its ruins are even now of great extent, and in an early part of the Chriſtian æra, it was the capital of Hindooſtan, or rather of the principal kingdom along the Ganges, and is poſſibly the place meant by Pliny for Calinipaxa. It is at preſent reduced to the ſize of a middling town. It is ſaid to have been built more than 1000 years before our æra ; and is mentioned in Feriſhta (326 years B. C.) as the capital of all Hindooſtan, under the predeceſſor of Phoos, or Porus, who fought againſt Alexander. Canoge correſponds, with regard to extent and magnificence, to the deſcription given of Palibothra, and in ſome reſpects, to the local poſition aſſigned to it by Ptolemy and Eratoſthenes ; but other authorities aſſign this place to Patna. The Indian hiſtories abound with the accounts of its grandeur, and populouſneſs. Its walls are ſaid to have been 100 miles in circumference, and its third emperor, Sinkal, could bring into the field 400 elephants, 100,000 horſe, and 400,000 foot. In the ſixth century it was found to contain 30,000 ſhops, in which betel nut was ſold, 3000 jewellers, and 60,000 bands of muſicians, who paid a tax to government. In the year 1018 it was ſeized by the Gaznian emperors, at which time it gave its name to the kingdom, of which it was the capital. It is diſtant from Agra 127 miles; from Benares 259 ; from Bombay 889 ; from Calcutta by Moorſhedabad 824, by Birboom 719 ; from Delhi 214; from Lucknow 75 ; from Madras 1141 ; from Nagpour 486 ; from Ougein 464; and from Poonah 842. N. lat. 27° 3′. E. long. 80° 13′.

CANON, in *Eccleſiaſtical Hiſtory*, a perſon who poſſeſſes a prebend or revenue allotted for the performance of divine ſervice, in a cathedral, or collegiate church.

Canons are of no great antiquity: Paſchier obſerves, that the name canon was not known before Charlemagne; at leaſt the firſt we hear of are in Gregory de Tours, who mentions a college of canons, inſtituted by Baldwin XVI. archbiſhop of that city, in the time of Clotharius I. The common opinion attributes the inſtitution of this order to Chrodegangus, biſhop of Metz, about the middle of the eighth century.

Originally canons were only prieſts, or inferior eccleſiaſtics, who lived in community; reſiding by the cathedral church to aſſiſt the biſhop; depending entirely on his will; ſupported by the revenues of the biſhopric; and living in the ſame houſe, as his domeſtics or counſellors, &c. They even inherited his moveables till the year 817, when this was prohibited by the council of Aix-la-Chapelle, and a new rule ſubſtituted in the place of that which had been appointed by Chrodegangus, and which was obſerved for the moſt part in the weſt till the twelfth century. By degrees theſe communities of prieſts, ſhaking off their dependence, formed ſeparate bodies; whereof the biſhops, however, were ſtill heads. In the tenth century there were communities, or congregations of the ſame kind, eſtabliſhed even in cities where there were no biſhops: theſe were called collegiates, and as they uſed the terms congregation and college indifferently: the name chapter, now given to theſe bodies, being much more modern. Under the ſecond race of the French kings, the canonical, or collegiate life, had ſpread itſelf all over the country; and each cathedral had its chapter, diſtinct from the reſt of the clergy.

They had the name canon from the Greek κανων, which ſignifies three different things; a rule, a penſion, or fixed revenue to live on, and a catalogue or matricula; all which are applicable to them.

In time, the canons freed themſelves from their rules, the obſervance relaxed, and at length they ceaſed to live in community; yet they ſtill formed bodies; pretending no other functions beſides the celebration of the common office in the church; yet aſſuming the rights of the reſt of the clergy; making themſelves as a neceſſary council of the biſhop; taking upon them the adminiſtration of a ſee during a vacancy, and the election of a biſhop to ſupply it. There are even ſome chapters exempt from the juriſdiction of the biſhop, and owning no head but their dean. After the example of cathedral chapters, collegiate ones alſo continued to form bodies, after they had abandoned living in community.

Canons are of various kinds; as,

CANONS, *cardinal*, or thoſe attached, and as the Latins call it, *incardanati* to a church, as a prieſt is to a pariſh.

CANONS, *domicellary*, were young canons, who not being in orders, had no right in any particular chapters.

CANONS, *expectative*, were ſuch as, without having any revenue or prebend, had the title and dignities of canons, a voice in the chapter, and a place in the choir, till ſuch time as a prebend ſhould fall.

CANONS, *foreign*, were ſuch as did not officiate in the canonries to which they belonged.—To theſe were oppoſed *manſionary canons*, or *canons reſidentiary*.

CANONS, *lay* or *honorary*, are ſuch among the laity, as have been admitted, out of honour and reſpect, into ſome chapter of *canons*.

CANONS *regular*, are *canons* that ſtill live in community; and who, like religious, have, in proceſs of time, to the practice of their rules, added the ſolemn profeſſion of vows.

They are called *regulars*, to diſtinguiſh them from thoſe *ſecular* canons who abandoned living in community, and at the ſame time, the obſervance of the canons made as the rule of the clergy, for the mainterance of the ancient diſcipline.

The canons ſubſiſted in their ſimplicity till the eleventh, ſome ſay the twelfth century, when ſome of them, ſeparating from the community, took with them the name of canons, or acephalous prieſts, becauſe they declined to live in community with the biſhop; and thoſe who were left, thenceforth acquired the denomination of canons regular, and adopted moſt of the profeſſions of the rule of St. Auguſtine. This order of regular canons of St. Auguſtine was brought into England by Adelwald, confeſſor to Henry I. who erected a priory at Noſtel in Yorkſhire, and obtained for them the church of Carliſle as an epiſcopal ſee, with the privilege of chuſing their own biſhop. They were ſingularly protected and encouraged by Henry I. who gave them the priory of Dunſtable in 1107, and by queen Maud, who in the following year, gave them the priory of the Holy Trinity in London. It appears, that under the reign of Edward I. they had fifty-three priories.

CANONS, *tertiary*, thoſe who had only the third part of the revenues of the canonicate.

CANON, in an *Eccleſiaſtical Senſe*, is a law or rule, either of doctrine or diſcipline, enacted eſpecially by a council, and confirmed by the authority of the ſovereign.

Canons are properly deciſions of matters of religion; or regulations of the polity and diſcipline of a church, made by councils either general, national, or provincial. See COUNCIL.

Such are the canons of the council of Nice, or Trent, &c. See CONSTITUTIONS.

There have been various collections of the canons of the Eaſtern councils; but four principal ones, each ampler than the preceding. The firſt, according to Uſher, A. D. 380, containing only thoſe of the firſt œcumenical council, and the firſt provincial ones: they were but 164 in number. To theſe, Dionyſius Exiguus, in the year 520, added the fifty canons of the apoſtles, and thoſe of the other general councils. The Greek canons in this ſecond collection, end with thoſe of the council of Chalcedon; to which are ſubjoined thoſe of the council of Sardica, and the African councils. The fourth and laſt collection comes down as low as the ſecond council of Nice; and it is on this that Balſamon and Zonaras have commented. See Hardouin's Acta Conſiliornm et Epiſtolæ decretales ac Conſtitutiones Summorum Pontificum, in 11 tomes; commencing with the year 34, and terminating in 1714. Prol. Paris, 1715.

CANONS, *Apoſtolical*, are thoſe which have been uſually aſcribed to St. Clement, in order to procure for them a high degree of authority. They contain a view of the church government and diſcipline received among the Greek and oriental Chriſtians in the ſecond and third centuries. Bellarmin, Baronius, &c. will have them to be genuine canons of the apoſtles. Cotelerius obſerves, (Jud. de. Canon. Ap. ap. Patr. Ap. t. 1.) that they cannot be aſcribed to the apoſtles or Clement, becauſe they are not received with other books of Scripture, are not quoted by the writers of the firſt ages, and contain many things not agreeable to the apoſtolical times. Hincmar, De Marca, Beveridge, &c. take them to be framed by the biſhops who were the diſciples of the apoſtles in the end of the ſecond and beginning of the third centuries. Beveridge (Cod. Can. Vindicat. l. i. c. x. 4.) acknowledges that they are interpolated in ſeveral places, though he profeſſes a great veneration for them, and has undertaken to defend them. The biſhop aſcribes a kind of apoſtolical authority to the 50th canon, which requires of the biſhops and preſbyters that they ſhould make uſe of a three-fold immerſion in baptiſm, under pain of being depoſed. The 69th canon ſtrictly

It requires the obſervation of the quadrageſimal faſt, under ſpiritual pains and penalties; and this, together with other ſtated faſts, Beveridge ſuppoſes to have been of apoſtolical inſtitution. S. Baſnage is of opinion, that they were collected by an anonymous writer in the fifth century; but Daille, &c. maintain them to have been forged by ſome heretic in the ſixth century; and S. Baſnage conjectures, that ſome of them are ancient, and others not older than the ſeventh century. The 85th canon contains a catalogue of the books of the Old and New Teſtament; which, from the books of the New Teſtament, that are enumerated in it, could not have been drawn up till after the third century. The epiſtle to the Hebrews was rejected, or doubted of by many in the firſt three centuries, and alſo in the fourth century; but if this canon had been then in being, and acknowledged as apoſtolical, that epiſtle would have been received by all. Several of the catholic epiſtles, that of James, the ſecond of Peter, the ſecond and third of John, and that of Jude, were rejected, or doubted of by many in the early times of Chriſtianity; whereas they would have been received by all, if this canon had been in being, or had been acknowledged to be apoſtolical. This argument is urged by Mill, in his "Prolegomena," p. 201. Moreover, the Revelation was received by many in the ſecond, and third, and following centuries, which would not have been the caſe, if there had been a canon compoſed by the apoſtles, or Clement their companion, in which all other books of Scripture were diſtinctly enumerated, and that omitted. How, ſays Baronius to this purpoſe, could ſo many of the Latin and Greek writers receive the Revelation, which was wanting in an apoſtolical canon? And how could there have been ſuch different opinions about the epiſtle to the Hebrews, and ſeveral of the catholic epiſtles, if they had been made canonical by an apoſtolical decree? Beſides, the firſt epiſtle of Clement was reckoned canonical by very few, if any of the writers of the firſt three centuries; therefore this pretended apoſtolical canon, which gives it a place among books of ſacred Scripture, was not in being; and the ſecond epiſtle of Clement was not eſteemed his in the third century, though the catalogue of this canon includes it. The Greek church allows only 85 of theſe canons, and the Latins only 50; though there are 84 in the edition given of them in the "Corpus Juris canonici." See Lardner's works, vol. iv. p. 354., and Jortin's Rem. on Eccles. Hiſt. vol. i. p. 278. &c. Cave, Hiſt. Lit. vol. i. p. 29. Jones's New and Full Method of ſettling the Canonical Authority of the New Teſtament, vol. i. p. 25.

Canon, is alſo uſed for the authorized catalogue of the ſacred writings. The word is originally Greek, Κανων, and ſignifies a rule or ſtandard, by which other things are to be examined and judged. Accordingly the ſame word has been applied to the "tongue of a balance," or that ſmall part, which, by its perpendicular poſition, determines the even poize or weight, or, by its inclination either way, the uneven poize of the things which are weighed. To this purpoſe is the obſervation of the ancient ſcholiaſt of Ariſtophanes in Ran. v. 809. Hence it appears, that as the writings of the prophets, apoſtles, and evangeliſts contain an authentic account of the revealed will of God, they are the rule of the belief, and practice of thoſe who receive them.

Canon ſeems alſo ſometimes to be equivalent to a liſt or catalogue, in which are inſerted thoſe books, that contain the rule of faith. Hence Du Pin, and others, have ſuppoſed, that theſe books are called canonical, becauſe they are placed in the catalogue of ſacred books. It has been ſaid, however, that the Greek word is never uſed in this ſenſe, by any prophane writers, nor even among the Chriſtians, till the fourth century; before which time the word was certainly applied to the ſacred volume. Mr. Whiſton (Eſſay on the Apoſtolical Conſtit. chap. i. §. 6.) imagines the canon of Scripture, or the canonical books of the Old and New Teſtament, to be thoſe, and only thoſe, which are inſerted in the laſt apoſtolical canon, and that they were ſo ſtiled by the ancients only on that account. But as the ſpuriouſneſs of theſe pretended apoſtolical canons is very generally allowed, it is needleſs to refute this opinion. See *Apoſtolical* Canons.

The uſe of this appellation, as applicable to the books of Scripture, is undoubtedly very ancient. St. Paul has twice uſed the word canon, or rule. Gal. vi. 16. Philip, iii. 16. And though in theſe paſſages he may refer to the doctrine of the goſpel in general, or to ſome particular maxim of it, and not to any books containing the rule of faith, yet his uſe of the word may have given occaſion for fixing that denomination to the books of Scripture. Irenæus, ſpeaking of the Scriptures, (Adv. Hæres. l. iv. c. 69.) ſtiles them τον κανονα της αληθειας, i. e. the canon of truth; and here canon is not a catalogue, but the books, or the doctrine contained in the books of Scripture. Clement of Alexandria, (Strom. l. 4. p. 453.) diſputing with ſome heretics of his time, blames them for making uſe of apocryphal Scriptures, "chuſing to follow any thing, rather than the true evangelical canon (or the canon of the goſpel)." In another place (Strom. l. vi. p. 676.) he ſays, "the eccleſiaſtical canon is the conſent and agreement of the law and the prophets with the Teſtament delivered by the Lord." Euſebius (Hiſt. Eccleſ. l. vi. c. 25.) tells us, that Origen, in his expoſition on Matthew, enumerates the books of Scripture according to the canon of the church; i. e. the canon received and eſtabliſhed in the church. Athanaſius, in his Feſtal epiſtle, mentions three ſorts of books, the canonical, which are thoſe now received by us, ſuch as were allowed to be read, and ſuch as are apocryphal, by which he means books forged by heretics. In the Synopſis of Scripture, which ſome have aſcribed to him, but probably not written till 100 years after his time, near the end of the fifth century, there occurs frequent mention of canonical and uncanonical books. The council of Laodicea, about 363, ordains, that "no books, not canonical, ſhould be read in the church, but only the canonical books of the Old and New Teſtament." The third council of Carthage, about 397, ordains, "that nothing beſide the canonical Scriptures be read in the church under the name of Divine Scriptures." Epiphanius, Philaſtrius, Rufinus, Jerome, Auguſtine, Chryſoſtom, Iſidore of Peluſium, and Leontius of Conſtantinople, uſe the words canon and canonical in the ſame ſenſe. Hence we may infer, how much the uſe of theſe words, canon and canonical, has obtained among Chriſtians, to denote thoſe books, which are of the higheſt authority, and the rule of faith; as oppoſed to all others whatever, particularly to eccleſiaſtical, or the writings of orthodox and learned catholics, and to apocryphal, the productions, chiefly of heretics, which by a ſpecious name and title made a pretenſion to be accounted among ſacred books. The moſt common and general diviſion of the canonical books is that of ancient and new, or the Old and New Teſtament.

The canon of the Old Teſtament is much more eaſily ſettled than that of the New; becauſe whatever almoſt may be objected againſt the authority of the preſent canon of the former, either in behalf of any books which are not in it, or againſt any that are, may be anſwered by this ſingle conſideration, viz. that we receive the ſame and no other books than ſuch as were received by the Jewiſh church in the time of our Saviour, as is evident from the copies of them procured by the Chriſtians, and the catalogues they made of them ſoon after the deſtruction of Jeruſalem. Some difference,

ence, however, has occurred in the mode of their arrangement. Hody ſays (de Bib. Text. Orig. l. ii. c. 9. p. 190.) that the diviſion of the ſacred books into the Law, the Prophets, and Chetubhim, or Hagiographa, is of the higheſt antiquity. The Jews are ſaid by ſome, but as others think, without ſufficient evidence, to have aſcribed it to the prophet Ezra. Although the Jewiſh people have been very uniform in the number of ſacred books received by them, they have varied, and have been ſomewhat arbitrary, in the general denominations and diviſions of them. Iſaac Voſſius ſuſpects that the above mentioned diviſion, was an invention of Aquila, who, in the ſecond century, made a new verſion of the Jewiſh ſcriptures into Greek; whereas, the old partition was that of the Law, the Prophecies, and Pſalms. Dr. Lardner obſerves, that no traces of it appear in the Scriptures of the Old or New Teſtament, nor in Joſephus, nor in Philo, nor in any Chriſtian writers before Epiphanius and Jerom, near the end of the fourth century. Some, indeed, have ſuppoſed that this tripartite diviſion is referred to in Luke, xxiv. 44; but other learned and judicious perſons, as Leuſden and Wolfius, are of opinion that by the "Pſalms" in this place we are not to underſtand the metrical books, or any other general diviſion of the ſcriptures of the Old Teſtament, but the book of Pſalms. J. Fr. Buddeus, (Hiſt. Eccleſ. Vet. Teſt. tom. poſterior, p. 828, 4to. Halæ Magdeb. 1719.) cited by Lardner, ſays it is uncertain when and by whom this partition was firſt uſed; and he alſo ſhews the impropriety and inconvenience of it, as generally uſed by the Jews. It does not appear that any notice is taken of it, or regard had to it in Melito, Origen, Cyril, or Athanaſius. Among thoſe who have uſed this partition, there ſeems to have been a great variety of opinions concerning the books that ſhould be called "Hagiographa." The term has nothing in it appropriating and diſtinctive, and this may have been the ground of that difference of opinion among thoſe who have uſed it, concerning the books that ſhould be placed in this claſs. Every other partition of the ſacred books of the Old Teſtament, with which we are acquainted, ſeems, in the judgment of Dr. Lardner, to be preferable to this of the Law, Prophets, and Hagiographa. Thoſe denominations, which we ſometimes meet with in the New Teſtament, the "Law," or "the Prophets," denoting in general the ancient ſacred writings, are very juſt. The dichotomy, "the Law and the Prophets," ſo common in the New Teſtament, is very proper. The tripartite diviſion in Luke, xxiv. and Joſephus, "the Law, the Prophets, and Pſalms or Hymns," is alſo very proper. Another partition is that uſed by Cyril of Jeruſalem, viz. legal, hiſtorical, metrical, and prophetical, which ſeems to have been regarded by Athanaſius, Origen, and Melito, in their catalogues, appears to Lardner and others the moſt proper and commodious.

Some have placed the books of the Old Teſtament from the firſt to the laſt, in chronological order. This, however, is a matter of no importance, and might be found inconvenient. But if they are divided into claſſes, the order of time may be uſeful. Accordingly, in the firſt claſs, muſt be the five books of Moſes; then the hiſtorical books, Joſhua, Judges with Ruth, Samuel, the Kings, the Chronicles, Ezra, Nehemiah, Eſther; next the metrical books, Job, the Pſalms, the Proverbs, Eccleſiaſtes, the Canticles; laſtly, the prophetical books, the twelve prophets in one book, each of which might be placed, according to the order of time, Iſaiah, Jeremiah with the Lamentations, Ezekiel, Daniel; or, firſt of all, the four larger prophets, and then the book of the twelve leſſer prophets, as they are called: by which we perceive, that the preſent order of books in our Bibles is, in the main, ſuch as we have reaſon to be well ſatisfied with.

The firſt catalogue of the books of the Old Teſtament recorded by any Chriſtian writer is that of Melito, biſhop of Sardis, in Lydia, who is placed by Cave at the year 170. He travelled into Paleſtine on purpoſe to learn the number of theſe books. Euſebius has preſerved his catalogue, and he ſays, that it is a catalogue of the ſcriptures of the Old Teſtament univerſally acknowledged. It contains the books received by the Jews into their canon; but he does not mention the book of Eſther. The order in which he enumerates them is as follows, viz. five books of Moſes, Joſhua, Judges, Ruth, four books of the Kings, two books of Chronicles, the Pſalms of David, the Proverbs of Solomon, the Eccleſiaſtes, the Canticles, Job, the books of the Prophets Iſaiah, Jeremiah, the 12 Prophets in one book, Daniel, Ezekiel, Ezra. Origen, about 230, has a catalogue, in which the books occur in the following order, viz. five books of Moſes, Joſhua, Judges with Ruth, one book; the firſt and ſecond book of the Kings, called by them Samuel, and reckoned one book; the third and fourth of the Kings, alſo one book; the firſt and ſecond of the Remains, in one book; Eſdras, firſt and ſecond, in one book, called by them Ezra; the book of the Pſalms; Solomon's Proverbs, Eccleſiaſtes, Canticles, Iſaiah, Jeremiah, Daniel, Ezekiel, Job, Eſther. The book of the Twelve Prophets is wanting in our copies. Athanaſius, in his Feſtal Epiſtle, and alſo in the Synopſis Scripturæ, aſcribed to him, enumerates the books in this order, viz. firſt, the five books of Moſes; then the hiſtorical books, from Joſhua to Ezra; then, the books in verſe, the Pſalms, Proverbs, Eccleſiaſtes, Canticles, Job; laſtly, the Prophets, which are the Twelve Prophets in one book, Iſaiah, Jeremiah, Ezekiel, and Daniel. Cyril of Jeruſalem, about 348, has a catalogue, in which he uſes diviſions. The firſt are the five books of Moſes; then the hiſtorical books; after them, five books in verſe, Job, the Pſalms, the Proverbs, Eccleſiaſtes, the Canticles; and, laſt of all, five prophetical books, which are the Twelve Prophets, in one book, Iſaiah, Jeremiah, Ezekiel, Daniel. Epiphanius, about 368, has three catalogues; in two of which all the books of the Old Teſtament are enumerated from Geneſis to Ezra or Eſther, without any partitions. But in the other he divides them, obſerving, that the books of ſcripture are compriſed in four Pentateuchs, and two over and above the firſt Pentateuch, or that which is moſt properly ſo, containing the five books of the Law: the next contains the five books in verſe, the book of Job, the Pſalter, the Proverbs of Solomon, the Eccleſiaſtes, the Canticles: the third Pentateuch contains thoſe called Graphica, by others Hagiographa, which are the book of Joſhua, the book of Judges with Ruth, the firſt and ſecond of the Remains, the firſt and ſecond of the Kingdoms, and the third and fourth of the Kingdoms: the fourth Pentateuch conſiſts of the Twelve Prophets, in one book, Iſaiah, Jeremiah, Ezekiel, Daniel; the two others, over and above theſe, are the two books of Ezra, reckoned one book, and Eſther. This catalogue is followed by John Damaſcenus, about the year 830. Jerom, A. D. 392, enumerates 22 books of the old law, according to the number of the Hebrew letters; viz. five books of Moſes, viz. Geneſis, Exodus, Leviticus, Numbers, and Deuteronomy; eight of the prophets, viz. Joſhua, Judges with Ruth, Samuel, Kings, Iſaiah, Jeremiah, Ezekiel, and the Twelve Prophets; and nine of the Hagiographa, viz. Job, David or the Pſalms, Solomon comprehending three books, i. e. Proverbs, Eccleſiaſtes, and the Song of Songs; Daniel, Chronicles, Ezra, and Eſther. Hence we ſee, that St.

Jerom's canon of the Old Teſtament was that of the Jews. All other books not received by them, he calls Apocryphal. See APOCRYPHAL.

In the catalogue of Rufinus, about the year 397, the books of the Old Teſtament are enumerated in the following order; viz. in the firſt place, are the five books of Moſes, Geneſis, Exodus, Leviticus, Numbers, Deuteronomy. After theſe are Joſhua and Judges, together with Ruth. Next the four books of the Kingdoms, which the Hebrews reckon two; the book of the Remains, which is called the Chronicles, and two books of Ezra, which by them are reckoned one, and Eſther. The prophets are Iſaiah, Jeremiah, Ezekiel, and Daniel; and beſides, one book of the Twelve Prophets: Job alſo, and the Pſalms of David. Solomon has left three books to the churches, the Proverbs, Eccleſiaſtes, and the Song of Songs. In the third, otherwiſe called the ſixth, council of Carthage, aſſembled in 397, it was ordained, that nothing beſide the canonical ſcriptures ſhould be read in the church under the name of Divine Scriptures; and that the canonical ſcriptures are theſe, Geneſis, Exodus, Leviticus, Numbers, Deuteronomy, Joſhua, Judges, Ruth, four books of the Kingdoms, two books of the Remains, Job, David's Pſalter, five books of Solomon, the books of the twelve prophets, Iſaiah, Jeremiah, Ezekiel, Daniel, Tobit, Judith, Eſther, two books of Ezra, and two books of the Maccabees. Upon this canon it has been remarked, that this council was not general, but provincial, or national; that the biſhops aſſembled do not ſhew much learning or judgment, when they reckon five books of Solomon; that the decree of this council, by placing among canonical ſcriptures Tobit, Judith, and the two books of the Maccabees, contradicts antiquity, or ought to be explained with a diſtinction; the word canonical being uſed laxly, ſo as to comprehend not only thoſe books which are admitted as the rule of faith, but thoſe alſo which are eſteemed uſeful, and may be publicly read for the edification of the people: and that this council mentions only two books of Ezra, meaning, probably, the book of Ezra properly ſo called, and the book of Nehemiah; but nothing is ſaid of the other two, ſometimes called the third and fourth books of Ezra. According to Auguſtine, (De Doctrin. Chriſt. l. ii. c. 8. tom. iii. p. i. Bened.) about 397, the entire canon of ſcripture is the following books, which he thus enumerates. There are five of Moſes, that is, Geneſis, Exodus, Leviticus, Numbers, Deuteronomy; one book of Joſhua; one of the Judges; one ſmall book called Ruth, which ſeems rather to belong to the beginning of the Kingdoms; then the four books of the Kingdoms, and two of the Remains, not following one another, but proceeding, as it were, parallel on the ſide of each other. Theſe are hiſtorical books, which contain a ſucceſſion of times in the order of events. There are others which do not obſerve the order of time, and are unconnected together: as Job, Tobit, Eſther and Judith, and the two books of the Maccabees, and the two books of Eſdras; which laſt do more obſerve the order of a regular ſucceſſion of things, after that contained in the Kingdoms and Remains. Next are the Prophets; among which is one book of the Pſalms of David, and three of Solomon, the Proverbs, the Song of Songs, and Eccleſiaſtes. For thoſe two books, Wiſdom and Eccleſiaſticus, are called Solomon's for no other reaſon but becauſe they have a reſemblance with his writings; for it is a very general opinion, that they were written by Jeſus, the ſon of Sirach: which books, however, ſince they are admitted into authority, are to be reckoned among prophetical books. The reſt are the books of thoſe who are properly called prophets: as the ſeveral books of the twelve prophets, which, being joined together and never ſeparated, are reckoned one book. The names of which prophets are theſe; Hoſea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habbakkuk, Zephaniah, Haggai, Zechariah, Malachi. After them are the four prophets of larger volumes; Iſaiah, Jeremiah, Daniel, Ezekiel. In theſe 44 books is compriſed all the authority of the Old Teſtament.

From this extract it appears, that there was not then any canon of ſcripture ſettled by any authority, that was univerſally acknowledged by chriſtians. Though there might be decrees of councils relating to this matter, they were not eſteemed deciſive and of authority, every where, and by all. But ſtill private and inquiſitive chriſtians had a right to uſe their own judgment concerning this point. Although Auguſtine ſays, that Wiſdom and Eccleſiaſticus ought to be reckoned among prophetical books, &c.; yet Rufinus and Jerom, who were a little older, muſt be allowed to bear a right teſtimony, and to declare truly what was the ſentiment of moſt chriſtian churches, when they ſay, that "the Wiſdom of Solomon, Eccleſiaſticus, Tobit, Judith, and the Maccabees, were indeed allowed to be publicly read: but that nevertheleſs they were not canonical, and that no doctrine of religion may be proved by their authority." From other paſſages in the works of Auguſtine it appears, that he acknowledged only 3 books of Solomon to be his; the Proverbs, Eccleſiaſtes, and Canticles; and that the Jews have no more of his writings in their canon. With regard to the books of Wiſdom and Eccleſiaſticus, he obſerves, that though they were eſteemed by ſome, on account of ſome reſemblance of ſtyle and deſign, to be Solomon's, the learned are ſatisfied they are not his; and that they were chiefly reſpected by the Weſtern chriſtians. He particularly owns that the book of Judith was not in the Jewiſh canon. Auguſtine, indeed, often quotes thoſe books of the Old Teſtament which we now generally call apocryphal, as Wiſdom, Tobit, Eccleſiaſticus, and the Maccabees; but he frequently uſes expreſſions which ſhew they were not eſteemed the books of the prophets, or of equal authority with the books of the Jewiſh canon. In his "Retractations" (l. i. c. 20,) he owns his miſtake in quoting the book of Eccleſiaſticus as prophetical; when it was not certain that it was written by a prophet. He alſo ſays in another place, (l. ii. c. 20) that he had not any proof of ſome propoſitions which he had advanced, but from the book of Wiſdom, which the Jews did not receive as of canonical authority. In another work written about the year 420, he ſays, "The Jews do not receive the ſcripture of the Maccabees as they do the Law, and the Prophets, and the Pſalms, to which our Lord bears teſtimony, Luke xxiv. ſo that upon the whole, Auguſtine ſeems not to differ from Jerom and Rufinus. For the teſtimonies of other ancient writers, Chryſoſtom, Theodoret, Coſmas of Alexandria, Gregory biſhop of Rome, Leontius, &c. to the Jewiſh canon, we muſt refer to Lardner, *ubi infra.* In the Stichometry of Nicephorus, patriarch of Conſtantinople, who flouriſhed in the beginning of the ninth century, we have a catalogue of the books both of the Old and New Teſtament. The divine ſcriptures mentioned in this work as received by the church and reckoned canonical, are; Geneſis, Exodus, Leviticus, Numbers, Deuteronomy, Joſhua, Judges, and Ruth, the firſt and ſecond books of the Kingdoms, the third and fourth of the Kingdoms, the firſt and ſecond of the Remains, Ezra, firſt and ſecond, the book of Pſalms, the Proverbs of Solomon, Eccleſiaſtes, the Song of Songs, Job, Iſaiah the prophet, Jeremiah the prophet, Baruch, Ezekiel, Daniel, and the 12 prophets. All together, it is ſaid, the books of the Old Teſtament are 22. The contradicted books are, three books of the Maccabees, the Wiſdom of Solomon, the

Wiſdom of Jeſus, the Son of Sirach, Pſalms, and Odes of Solomon, Eſther, Judith, Suſanna, and Tobit, called alſo Tobias. The inſertion of the book of Baruch, among the ſacred ſcriptures of the Old Teſtament, is the only circumſtance in which this catalogue differs from that of the Jews; but this, and the omiſſion of Eſther, which was not in all ancient catalogues, may be reckoned things of no great conſequence. In the Stichometry prefixed by Cotelerius to the apoſtolical conſtitutions there are 60 books of the Old and New Teſtament, among which are placed 3 books only, which we call Solomon's, the Proverbs, Eccleſiaſtes, and the Canticles; the other two, ſometimes aſcribed to him, Wiſdom and Eccleſiaſticus, are placed with thoſe, which are not of the 60, or contradicted books. Among the 60 there is but one book of Ezra, probably meaning our Ezra and Nehemiah; but among the apocryphal is a book called the Revelation of Ezra. The book of Eſther is not placed among the 60, but in the ſecond claſs of ſuch as were reckoned uſeful. See BIBLE.

The canonical books of the New Teſtament, received by chriſtians in this part of the world, are the Four Goſpels, the Acts of the Apoſtles, 14 Epiſtles of St. Paul, ſeven catholic Epiſtles, and the Revelation. Dr. Lardner ſuggeſts, that the beſt canon of the New Teſtament, is that which may be collected from Euſebius of Cæſarea, and which ſeems to have been the canon of ſome in his time. The canon ſhould conſiſt of two claſſes: the *firſt* conſiſting of thoſe books, called Ομολογȣμενα, which he aſſures us were then univerſally acknowledged, and had been uniformly received, by all catholic chriſtians; theſe are the four goſpels, the Acts of the Apoſtles, 13 epiſtles of St. Paul, one epiſtle of St. Peter, and one epiſtle of St. John. Theſe only ſhould be eſteemed of the higheſt authority, from which doctrines of religion may be proved. The *ſecond* claſs comprehends thoſe books of which Euſebius ſpeaks, called αντιλεγομενα, as contradicted in his time, though well known; concerning which there were doubts, whether they were written by perſons whoſe names they bear, or whether the writers were the Apoſtles of Chriſt. Theſe are the epiſtle to the Hebrews, the epiſtle of James, the ſecond of Peter, the ſecond and third of John, the epiſtle of Jude, and the Revelation. Theſe ſhould be reckoned doubtful, and contradicted; though many might be of opinion, that there is great reaſon to believe them genuine. They ſhould be allowed to be publicly read in chriſtian aſſemblies, for the edification of the people; but not to be alleged, as affording, alone, ſufficient proof of any doctrine. Euſebius reckons a *third* claſs of books of the New Teſtament, called νοϑα, ſpurious; but Dr. Lardner obſerves, that there ſhould be no ſuch third claſs of ſacred books; foraſmuch as there appears not any reaſon from chriſtian antiquity to allow of that character and denomination to any chriſtian writings, beſide thoſe above-mentioned. This canon is a good one, becauſe it is ſhort, and contains only thoſe books, which were acknowledged by all in the time of Euſebius, and from the beginning; and ſeven others, which were then well known, and are next in eſteem to thoſe that were univerſally acknowledged; and were generally received as of more authority than any other controverted writings. Nor is there in them any thing inconſiſtent with the facts, or the principles delivered in the books, univerſally acknowledged. Moreover, there may be a great deal of reaſon to think, that they are the genuine writings of thoſe, to whom they are aſcribed, and that the writers were Apoſtles. No other books, beſide thoſe now generally received by us, ought to be eſteemed canonical, or books of authority. The books contained in this canon, were written by ſeveral perſons, in ſeveral places, and at different times; and it is, therefore, reaſonable to think, that it was formed gradually. At the riſe of the chriſtian religion, there were no written ſyſtems or records of it; nor, indeed, was it fit, that any books ſhould be written about it, till there were converts to receive and keep them, and deliver them to others. In proceſs of time, the writings of the apoſtles and evangeliſts would be reſpectfully received by chriſtian proſelytes, as the written word of God, or ſacred Scriptures. Thoſe who received them would embrace the opportunities that occurred of conveying them to others; and thoſe who received them were fully aſſured of their genuineneſs by thoſe who delivered them. Before the end of the firſt century, or, indeed, not very long after the middle of it, it is likely, there were collections made of the four goſpels, and of moſt of the other books of the New Teſtament, which were in the hands of a conſiderable number of individuals and of churches. From quotations of ſome and from the writings of Irenæus, Clement of Alexandria, Tertullian, and other writers of the ſecond century, of Origen in the third, and of Euſebius in the fourth century, it appears, that moſt of the books, now received by us, and called canonical, were univerſally acknowledged in their times, and had been ſo acknowledged by the elders and churches of former times. And as to the reſt, now received by us, though they were then doubted of, or controverted by ſome, they were well known, and approved by many. Athanaſius alſo, who lived not long after Euſebius, (having flouriſhed from the year 326, and afterwards), received all the ſame books, which are now received by us, and no others. This has been the prevailing ſentiment ever ſince. This canon was not determined by the authority of councils; but the books of which it conſiſts were known to be the genuine writings of the apoſtles and evangeliſts, in the ſame manner that we know the works of Cæſar, Cicero, Virgil, Horace, Tacitus, to be theirs. And the canon has been formed upon the ground of an unanimous, or generally concurring teſtimony and tradition.

That the number of books to be received as ſacred and canonical had not been determined by the authority of any council or councils, univerſally acknowledged, is apparent from the different judgments among Chriſtians, in ſeveral parts of the world, concerning divine books, particularly the Epiſtle to the Hebrews and the Revelation; which were received by ſome, rejected, or doubted of by others. This was alſo the caſe with reſpect to ſome of the catholic epiſtles. No ſuch authority had ſettled the canon of the New Teſtament in the time of Euſebius, becauſe he mentions no ſuch thing. There was no catalogue of the books of Scripture in any canon of the council of Nice, A. D. 325. Auguſtine, A. D. 397, giving directions to inquiſitive perſons, how they might determine what books are canonical, and what not, does not refer to the deciſions of any councils. Caſſiodorus, in the ſixth century, has three catalogues, one called Jerom's, another Auguſtine's, and another that of the ancient verſion; but without reference to the decree of any council, as deciſive. And it ſeems moſt probable, that in all times, Chriſtian people and churches had a liberty of judging for themſelves according to evidence; which evidence, with regard to the genuineneſs of moſt of the books of the New Teſtament, has been ſo clear and manifeſt, that they have been univerſally received. The genuineneſs of theſe books was determined by teſtimony, or tradition. The firſt teſtimony is that of thoſe who were cotemporary with the writers of them; and this teſtimony has been tranſmitted by others. That the primitive Chriſtians formed their judgment concerning the books of Scripture in this way, appears from their remaining works. Inſtances to this purpoſe might be collected from Clement of Alexandria, Tertullian, Origen, Euſebius, Athanaſius, Cyril, Ruſinus, and Auguſtine. But, beſides obſerving the teſtimony of writers in former times, they alſo criticized the books that were propoſed to them; examining their ſtyle and contents, and comparing them with thoſe books which had been already received, as genuine, upon the ground of an unanimous teſtimony, and undoubted tradition. Some indeed have ſaid, that the council of Laodicea, held probably A. D. 363, firſt ſettled the canon of the New Teſtament. But it may be juſtly ſaid to have been ſettled before. At leaſt, ſays Dr. Lardner, there had been long before a general agreement among Chriſtians, what books were canonical and what not. From the decree of the council itſelf it appears, that there were writings already known by the title of canonical. That council, in its laſt canon, merely declares, "that private pſalms ought not to be read in the church, nor any books not canonical, but only the canonical books of the Old and New Teſtament;" after which follows a catalogue or enumeration of ſuch books, in which are rejected the apocryphal books of the Old Teſtament, and the Revelation in the New Teſtament. The 47th canon of the council of Carthage, aſſembled A. D. 397, ordains, "that nothing beſides the canonical Scriptures be read in the church, under the name of divine Scriptures." This council's canon of the New Teſtament is the ſame as that now received, without any other later writings as canonical; though from the manner in which the Epiſtle to the Hebrews is mentioned, there is reaſon to ſuſpect, that it was not ſo generally received as the other 13 epiſtles of St. Paul. "We no where read," ſays Le Clerc (H. E. ann. 100. num. iii. iv. et ann. 29. num. xcii.) "of a council of the apoſtles, or of any aſſembly of the governors of Chriſtian churches, convened to determine by their authority, that ſuch a number of goſpels, neither more nor fewer, ſhould be received. Nor was there any need of it, ſince it is well known to all from the concurring teſtimony of cotemporaries, that theſe four goſpels are the genuine writings of thoſe whoſe names they bear; and ſince it is alſo manifeſt that there is in them nothing unworthy of thoſe to whom they are aſcribed, nor any thing at all contrary to the revelation of the Old Teſtament, nor to right reaſon. There was no need of a ſynod of grammarians, to declare magiſterially what are the works of Cicero, or Virgil. In like manner, the authority of the goſpels has been eſtabliſhed by general and perpetual conſent, without any decree of the governors of the church. We may ſay the ſame of the apoſtolical epiſtles, which owe all their authority, not to the deciſions of any eccleſiaſtical aſſembly, but to the concurring teſtimony of all Chriſtians, and the things themſelves which are contained therein." Upon the whole, we may conclude, that the writings of the apoſtles and evangeliſts are received, as the works of other eminent men of antiquity are, upon the ground of general conſent and teſtimony; nor does the canon of the Scriptures of the New Teſtament owe its eſtabliſhment to the deciſions of councils, but to the judgment of Chriſtian people in general; and the judgment is right and reaſonable.

If we refer to the writings of ancient authors, we ſhall find, that they had the ſame canon of the New Teſtament with that which is generally received in our times. Accordingly, the catalogue of canonical books furniſhed by Origen about A. D. 230; Euſebius, A. D. 315; Athanaſius, A. D. 326; Cyril, A. D. 348; (the book of Revelation excepted); Epiphanius, A. D. 368; Baſil and Gregory Nazianzen, and Amphilochius, A. D. 370; Gregory Nyſſen, A. D. 371; Jerom, A. D. 392; Auguſtine, A. D. 395; Rufinus, A. D. 397; Innocent I. biſhop of Rome, A. D. 402; Iſidore of Peluſium, and Cyril of Alexandria, A. D. 412; Caſſian, A. D. 424; Proſper of Aquitain, and Euſebius, biſhop of Lyons, and Sedulius, A. D. 434; Leo, biſhop of Rome, and Salvian, preſbyter of Marſeilles, A. D. 440; Dionyſius, falſely called the Areopagite, A. D. 490; Gelaſius, biſhop of Rome, A. D. 494; Andrew, biſhop of Cæſarea, A. D. 500; Facundus, an African biſhop, and Arethas, A. D. 540; Caſſiodorius, A. D. 556; Photius, patriarch of Conſtantinople, A. D. 858; Oecumenius, A. D. 950; Theophylact, A. D. 1070; (the Revelations excepted); and Nicephorus Calliſti, A. D. 1325; agrees with that which is now received among Chriſtians. We learn from Paul Sarpi's hiſtory of the council of Trent, that one of the doctrinal articles concerning Sacred Scripture, extracted, or pretended to be extracted out of Luther's works, was this: "that no books ſhould be reckoned a part of the Old Teſtament beſides thoſe received by the Jews: and that out of the New Teſtament ſhould be excluded the Epiſtle to the Hebrews, the Epiſtle of James, the ſecond of Peter, the ſecond and third of John, the Epiſtle of Jude, and the Revelation." And in that council there were ſome biſhops "who would have had the books of the New Teſtament divided into two claſſes; in one of which ſhould be inſerted thoſe books only which had been always received without contradiction; and in the other, thoſe which had been rejected by ſome, or about which at leaſt there had been doubts." Dr. Courayer, in his notes, ſeems to favour this propoſal. See his French tranſlation of the hiſtory of the council of Trent, (l. ii. c. 43. tom. i. p. 235, and c. 47. p. 240. note 1.). Concerning the difference of opinions that have ſubſiſted among ancient and modern writers, with reſpect to the authenticity of particular books, their authors, &c. ſee the titles of thoſe books, Hebrews, Peter, John, James, Jude, and Revelation, or Apocalypſe. For the time of writing the ſeveral books of the New Teſtament, and other particulars relating to them, ſee their reſpective titles. See alſo GOSPEL, ACTS, EPISTLE, and TESTAMENT. Thoſe who wiſh to examine this ſubject more at large, may conſult, beſides the well-known writings of Coſin, Richardſon, Nye, Jones, Lardner, Michaelis, Kennicott, &c. "Gerhardi de Maſtricht Canon Scripturæ ſacræ eccleſiaſticus," Jenæ, 1725; "Schmidii Hiſtoria antiqua et Vindicatio Canonis ſacri V. et N. T." Lipſiæ, 1775, and "Stoſchii Commentatio Hiſtorico-critica de Librorum N. T. Canone," Francof. ad Viadrum, 1755. Such perſons as are acquainted with German literature will find much new and curious information in Dr. Semler's "Freye Unterſuchung," or Free Inquiry into the Canon, 3 vols. 12mo. Halle, 1771—1773; Weber's "Beyträge zur Geſchichte des Kanons," Tübingen, 1791, and in Eichhorn's "Repertorium," vol. v. p. 217.

Some of the fathers have diſtinguiſhed the inſpired writings into three claſſes: proto-canonical, deutero-canonical, and apocryphal; which ſee reſpectively.

CANON, *paſchal*, a table of the moveable feaſts, ſhewing the day of Eaſter, and the other feaſts depending on it, for a cycle of nineteen years. The paſchal canon is ſuppoſed to be the calculation of Euſebius of Cæſarea, and to have been done by order of the council of Nice.

CANON, in *Monaſtic Orders*, a book wherein the religious of every convent have a fair tranſcript of the rules of their order, frequently read among them as their local ſtatutes. This is alſo called regula, as containing the rule and inſtitution of their order. The canon differs from the miſſale, martyrologium, and necrologium.

CANON, again, is uſed for the catalogue of ſaints acknowledged and canonized in the Roman church.

Canon is alſo uſed, by way of excellence, in the Romiſh church, for the ſecret words of the maſs, from the preface to the *Pater*; in the middle of which the prieſt conſecrates the hoſt. The common opinion is, that the canon of the maſs commences with *Te igitur*, &c. The people are to be on their knees, hearing the canon; and are to rehearſe it to themſelves, ſo as not to be heard.

Canon, in *Muſic*, from κανων, *regula*, a rule or law. In ſpeaking of harmonics, in the diviſion of the monochord, it implies the ratio of ſounds, or the proportion of ſound to ſound, when a ſtring is divided by moveable bridges into harmonic intervals. Hence Euclid's celebrated tract on harmonics, as well as Ptolemy's, is called *ſectio canonis*, the ſection of the canon.

But, in muſical compoſition, a *canon* is a law given by one part to another, or to ſeveral parts. As nothing is more difficult to compoſe than *canons*, ſo no ſpecies of compoſition has exerciſed ingenuity, meditation, and labour, in more various ways than the conſtruction of *canons*.

In the uniſon and octave, they are not only more eaſy to compoſe, but are more pleaſing to hear; as all other *canons* are moving in two or three different keys at the ſame time. But *canons* that are eaſy to write, and pleaſing to hear, are in no eſtimation among maſters and profound contrapuntiſts. They have no more reſpect for a *canon* in the uniſon and octave, than a geometrician for a ſum in addition; they regard canons as muſical problems, of which, if the ſolution is eaſy, they are unworthy of notice. They are, in reality, more calculated to exerciſe intellect, than delight the auricular ſenſe.

*Canons* in the 5th or 4th obtain the moſt reverence; but theſe ſervile imitations have been practiſed in the 2d, 3d, 6th, and even the 9th. But rigid fuguiſts call theſe only *imitations*, as the intervals are not ſimilar.

*Canons* were the laſt compoſitions which maſters condeſcended to publiſh in ſcore. They were regarded as enigmas, which required the deepeſt ſagacity and ſcience to unfold. All the ſeveral parts were written on one ſtaff, frequently without ſpecifying when, where, and in what interval the other parts came in. Sometimes, indeed, the compoſer was ſo indulgent as to place this character, 𝄋, over the firſt note of each of the other parts; but without indicating at what diſtance from the *propoſta*, or ſubject, or whether above or below it. At other times the performers were told what kind of *canon* it was, and how reſolved by a Greek or Latin term; that is, on what ſound the *riſpoſta*, or anſwer, was to be made. If in the 4th, 5th, 8th, &c. the words *diateſſaron*, *diapente*, *diapaſon*, &c. occur. If theſe terms are uſed ſimply and unaccompanied, they generally imply that the anſwer is made in ſuch interval above; but if ſome expletive is not added to the interval in which the anſwer is made, the performer is uncertain whether it is above or below the text or ſubject propoſed.

Padre Martini ſays (*Saggio di Contrappunto*) that there are ſo many *canons* ſtill preſerved of the old eccleſiaſtical compoſers, each of which is upon ſome peculiar conſtruction, that it would require a long treatiſe even ſuperficially to explain them.

A *canon* that is written and compoſed in a myſterious and ſingular manner, is called by the Italians *canone chiuſo;* a *canon* in ſcore, or clearly explained, *canone aperto*. A *canon* written only on one line, and ſeemingly in one part or melody, ſometimes has its ſolution pointed out by different clefs and reſts at the beginning. In old compoſers, whether the *riſpoſta* is made above or below the ſubject, is often determined by the Latin particle, *ſuper*, or *ſub*, or by the Greek *hyper*, or *hypo*. So many of the moſt ancient *canons* are locked up in the myſtery of enigmatical inſcriptions or mottos, that the good Padre Martini has collected and explained between 50 and 60 of theſe oracular decrees: ſuch as

1. *Clama ne ceſſes.*
2. *Ocia dant vitia.*
3. *Dii faciant ſine me non moriar ego.*
4. *Omnia ſi perdas famam ſervare memento,*
   *Qua ſemel amiſſa, poſtea nullus eris.*
5. *Sperari & preſtolari multos facit morari.*
6. *Ocia ſecuris inſidioſa nocent.*
7. *Tarda ſolet magnis rebus ineſſe fides.*
8. *Fuge morulas.*

Each of theſe enigmas implies, that the parts which anſwer the leader, are to pay no attention to the reſts, but to ſing the notes without them.

The 12 next enigmas imply nothing more than that the firſt of the two anſwers begins with the firſt note of the ſubject propoſed, and advances ſtraight forward to the end; while the ſecond anſwer begins at the end, and moves backward to the beginning.

It is eaſy enough (ſays M. Ginguené) to conceive the difficulty of conſtructing ſuch *canons*, and how impoſſible it is to divine the author's meaning, if ſome written clue is not given to it; but it is not ſo eaſy to conceive what pleaſure can reſult from the execution of ſuch a taſk, or the merit of taking ſuch great pains for ſo little pleaſure.

Dr. Pepuſch was very fond of theſe muſical myſteries; and the ſtudious and profound Padre Martini, to the end of his life, apologiſed for, and ſtrongly recommended the cultivation of them, to young muſicians, as ſtimuli to meditation and the ſtudy of recondite harmony. A cloſe canon is placed at the head of each chapter of his Hiſtory of Muſic, and whatever contempt and averſion modern faſhionable compoſers may affect for theſe pedantries, no muſician is willing to confeſs his ignorance of any part of the arcana of counterpoint, or to have it thought that he is *incapable* of making a canon; for the regular bred and deep harmoniſts of Italy and Germany ſtill reſpect the old Roman ſchool, and are not only pleaſed with a good fugue or canon, when they hear or ſee it, but add to the number whenever their ſcience and leiſure allow it.

Marpurg defines *canon*, "a muſical compoſition, in which the parts are diſperſed according to the rules of imitation."

In the ancient manner of writing all the ſeveral parts on one ſtaff, the ſolutions were pointed out by a *preſa*, or ſign of reference, 𝄋, or by numbers, indicating when the ſeveral parts come in, placed above or below the five lines, to point out which were above and which below the principal, and ſometimes by the mere title of the *canon*, as *ad diateſſaron*, &c.

Beſides *canon* in equal intervals and notes of equal value, there are others of augmentation and diminution; that is, when the ſubject is repeated by the 2d part in notes of double or of half the length of the firſt. There are canons likewiſe in *moto contrario*, *per arſin et theſin*, which ſee.

*Canons* in different ſpecies of octave, which all muſt be, except thoſe in the uniſon, octave, 4th and 5th, are only *imitations* (which ſee), though the parts move in the ſame kind of notes.

There are alſo canons on two, three, and four ſubjects, difficult to conſtruct, and ſtill more difficult for the hearer to comprehend; they are purely calculated to entertain the eye, but not the ear; as there is too much confuſion for that ſenſe to diſtinguiſh and follow the ſeveral melodies, or enjoy the ingenuity of the deſign. Geminiani has in a concerto of his op. 3ra. a movement in *canon* of four parts, uniſons, and octaves, which uſed to be admired; but he had another in his laſt concertos, op. 7ma. on four different ſubjects, which we believe was never performed in public, it produced ſo much confuſion in private.

To give a liſt of the principal writers on fugue and *canon* would be enumerating all the authors who have written on muſic from the 15th century to the preſent. The rules have been varied but little from Pietro Aron's time, though new contrivances and new enigmas have been multiplied without end.

Compoſition in plain and florid counterpoint ſhould be ſtudied, and its rules and exceptions well digeſted by a muſical ſtudent, before he attaches himſelf to fugue and *canon*, which will make him indifferent about *melody*, provided, under *canonical* reſtrictions, he can make his *harmony* correct.

All that now remains for us to do, in order to ſmooth the way in this kind of ſtudy when the young compoſer thinks it expedient to undertake it, is to give a few ſhort ſpecimens of the principal kinds of *canon* that have been cultivated by great maſters of the old ſchool, when nothing elſe was prized, and all their powers were devoted to that almoſt excluſively.

No writer has more clearly laid down the rules of fugue and *canon* than Dr. Pepuſch, as no one was more deeply read than he was in all the arcana of that kind of lore. Marpurg, Padre Martini, Kirnberger, and ſubſequent writers, may have ſomewhat extended and detailed the rules more minutely than the venerable graduate of one of our univerſities; but as far as he goes, we may ſafely depend on his doctrines. Concerning canon, his precepts are few and ſhort; but of fugues, both precepts and examples are not only numerous, but luminous and indiſputable, which rendered it leſs neceſſary to be diffuſe on *canon*, as the laws of fugue are the laws of *canon*, with reſpect to bringing in the anſwers of the ſeveral parts; and all the ſhort examples of *fugue* in Dr. Pepuſch's treatiſe are almoſt wholly in *canon*.

After fully treating of regular fugue, and its laws, he ſays: "Regular *fugues* are of two ſorts; the one is called by the Italians, *Fuga legata*, and the other *fuga ſciolta*. The firſt ſort is in Engliſh generally called *canon*, and we may expreſs the other by the name of *free fugue*.

"A Canon is that ſort of fugue in which the ſeveral parts ſtrictly contain the *ſame melody* from the beginning to the end; or in which the *guide* and the *anſwers* are, throughout the whole compoſition, exactly *alike*.

"A Free Fugue is not confined to this obligation; for in that we may introduce various ſubjects, different from the theme on which the *fugue* began, and break off alſo at pleaſure; however, *every* ſubject introduced is a *guide*, which muſt have its anſwer in the ſame *ſolmiſation* (intervals) as itſelf; and theſe *freſh ſubjects* muſt alſo be very regularly introduced, according to the *different keys* into which the modulation is brought, and which are *proper* to the *chief key* of the compoſition."

It ſeems as neceſſary for the accents of the anſwers to a canon to fall on the ſame parts of a bar, as in a fugue; particularly in ſetting words. Even in Sala's excellent examples of canon, when the ſubject is led off after a minim reſt in one part, and a ſemibreve reſt in the *riſpoſta*, or reply, the melody is ſo diſguiſed, and there is ſuch confuſion, that there is no canon, nor hardly an imitation, diſcoverable by the ear from the beginning to the end; ſo that all the pains and ingenuity that have been beſtowed on the conſtruction are thrown away; and if there is any melody in the firſt part, it is totally deſtroyed by the ſecond. For eminent writers on *canon*, expreſly, ſee Valentini, Michele, Rocco Rodio, and Bevin.

After all that has been ſaid in this long article, in favour of Canon as an ingenious contrivance, and of its utility among the ſtudies of young muſicians; we muſt own that *canons* which have no other merit than the difficulty of their conſtruction and ſolution, ſhould never ſee the light, being the mere offspring of pedantry and dulneſs; but that ſuch laborious works of this kind as are built on agreeable ſubjects, and are rich in harmony, may, in *ſociety*, afford great pleaſure to real lovers and judges of muſic, cannot be denied.

**Canon** of *Ptolemy*, in *Chronology*, a canon of the Chaldæan, Perſian, Grecian and Roman kings, compiled by Claudius Ptolemæus, who flouriſhed in Egypt in the reigns of Adrian and Marcus Antoninus, about A. D. 150, from the annals and hiſtories of the ſeveral kingdoms to which it relates, and eſteemed an invaluable treaſure in the ſcience to which it is ſubſervient. It has been preſerved in Commentaries of Theon, and publiſhed by Overall and Petavius from two MSS. in the royal library at Paris. In this canon the author computes from the epoch of the Nabonaſſarean æra, and from that day of the month on which the Egyptian Thoth fell. The years made uſe of are Egyptian, and conſiſt of 365 days, without intercalation. In every reign the years are reckoned as complete; and thoſe reigns which are leſs than a year, are omitted, whether they comprehended a Thoth or not. This defect was, in ſome degree, ſupplied by additions to other reigns: yet it appears in hiſtory, that a year was now and then miſreckoned. The firſt part of this canon has been improperly entitled "Ptolemy's Canon of the Kings of the Aſſyrians and Medes," as it includes none but kings of Chaldæa or Babylon.

Canon of *Ptolemy*.

Playfair's Chronology, p. 312.

Canon, in *Geometry* and *Algebra*, a general rule for the ſolution of all caſes of a like nature with the preſent inquiry. Thus every laſt ſtep of an equation is a canon; and, if turned into words becomes a rule to ſolve a queſtion of the ſame nature with that propoſed.

Canon, *natural, of triangles*, is a table of ſines, tangents, and ſecants together: ſo called, becauſe ſerving principally for the ſolution of triangles.

Canon, *artificial, of triangles*, is a table wherein the logarithms of ſines and tangents are laid down. See Sine, under which article the method of conſtructing the natural and artificial canon will be explained. See alſo Gunter, Gunter's Line, Scale, and Sector.

Canon *Law*, a collection of eccleſiaſtical conſtitutions, deciſions, and maxims, taken partly from Scripture, partly from the decrees of general and provincial councils, and partly from the decretal epiſtles and bulls of the holy ſee, and the reports and ſayings of the primitive fathers, whereby all matters of policy in the Roman church are regulated.

"If the canon law," ſays Dr. Robertſon (Hiſt. Charles V. vol. i. p. 74, &c. 8vo.) "be conſidered politically, either as a ſyſtem purſued on purpoſe to aſſiſt the clergy in uſurping powers and juriſdiction, no leſs repugnant to the nature of their function, than inconſiſtent with the order of government; or as the chief inſtrument in eſtabliſhing the dominion of the popes, which ſhook the throne, and endangered the liberties of every kingdom in Europe, we muſt pronounce it one of the moſt formidable engines ever formed againſt the happineſs of civil ſociety. But if we contemplate it merely as a code of laws reſpecting the rights and property of individuals, and attend only to the civil effects of its deciſions concerning theſe, we muſt view it in a different, and a much more favourable light." It is not eaſy to fix with preciſion the period at which eccleſiaſtics firſt began to claim exemption from civil juriſdiction. In the early and pureſt ages of the church, they made no pretences to ſuch immunity. The authority of the civil magiſtrate extended to all perſons, and to all cauſes. But in ages of ignorance and credulity, the miniſters of religion became objects of ſuperſtitious veneration. Accordingly we find in Tacitus, (de Mor. Germ.) that prieſts were highly reverenced by the Germans, and that they preſided in the aſſembly of the people. They alone were permitted to chaſtiſe, to bind, and to ſmite; which they did, not by order of the prince, or as his miniſters of juſtice; but as by an inſpiration of that Deity, who is always preſent to thoſe who make war. When the barbarians who over-ran the empire firſt embraced the Chriſtian faith, they found the clergy in poſſeſſion of conſiderable power, and they naturally transferred to theſe new guides the profound ſubmiſſion and reverence which they had been accuſtomed to yield to the prieſts of that religion which they had forſaken. The clergy, whoſe function was regarded as ſacred, availing themſelves of the advantage which the ſuperſtition and credulity of mankind afforded them, gradually emancipated themſelves from ſubjection to the profane juriſdiction of the laity and to civil courts; and extended that indulgence which ſeems at firſt to have been merely an act of complaiſance, flowing from veneration of their character, into a legal exemption. Hence they proceeded to eſtabliſh courts, in which every queſtion relating to their own character, their function, or their property, was tried. Upon different pretexts, and by a multiplicity of artifices, they communicated this privilege to ſo many perſons, and extended their juriſdiction to ſuch a variety of caſes, that moſt concerns which gave riſe to litigation were drawn under the cognizance of the ſpiritual courts.

Du-Cange, in his Gloſſary (Voc. *Curia Chriſtianitatis*) has collected moſt of the cauſes with reſpect to which the clergy arrogated an excluſive juriſdiction, and refers to the authors, or original papers, which confirm his obſervations. Giannoni, in his Civil Hiſtory of Naples, (l. xix. § 3.) has ranged theſe under their proper heads, and ſcrutinizes the pretenſions of the church with his uſual boldneſs and diſcernment. M. Fleury obſerves, (Hiſt. Eccleſ. tom. xix. Diſc. Prelim.) that the clergy multiplied, at ſuch a rate, the pretexts for extending the authority of the ſpiritual courts, that it was in their power to withdraw every perſon and every cauſe from the juriſdiction of the civil magiſtrate. The ambitious project of erecting a ſpiritual monarchy, ſuperior to all others, even in worldly power, was manifeſted by the whole conduct of the biſhops of Rome, and of the clergy connected with them, both before and after the period in which the canon law was introduced. This appeared in the canons enacted by their councils for the government of that monarchy; and it was very ſignally diſplayed in the canons of the provincial ſynod, held at Merton in Surrey, A. D. 1258, by Boniface, archbiſhop of Canterbury. The firſt canon of that ſynod forbids archbiſhops, biſhops, and inferior clergy, to appear before civil courts to anſwer for any part of their conduct which had the moſt remote relation to church affairs; and threatens the judges, and even the king himſelf, with the higheſt cenſures of the church, if they inſiſt on ſuch appearance. The ſecond relates to patronages; and the third is againſt the intruſion of clerks into benefices by a lay power. The fourth makes ſuch regulations concerning excommunication, as rendered that ſentence truly terrible. The fifth forbids laymen to impriſon clergymen. In the ſixth, the church claims a right of judging concerning contracts between a clergyman and a layman. The ſeventh aſſerts a right of the church to judge and puniſh Jews. The eighth provides for the perfect ſecurity of thoſe criminals who had taken refuge in churches. The ninth, tenth, and eleventh, are deſigned to prevent all invaſions of every kind in the poſſeſſions of the church and clergy, which are declared ſacred and inviolable. And the two laſt provide for the church's peaceable enjoyment of all pious legacies and donations. The viſible tendency of all ſuch canons was to emancipate the church and clergy from civil authority. We need not wonder then that the laity ſhould be alarmed at ſuch proceedings, whenever they occurred, and by the ambitious ſpirit which they indicated. In order, therefore, to diſpoſe the laity to ſubmit to uſurpations of this kind without oppoſition or murmur, it was neceſſary to convince them, that the adminiſtration of juſtice would be rendered more perfect by the eſtabliſhment of this new juriſdiction. Accordingly, howſoever ill-founded the juriſdiction of the clergy may be, and whatever might be the abuſes to which their manner of exerciſing it gave riſe, the principles and forms of their juriſprudence were far more perfect than that which was known in the civil courts. The eccleſiaſtics, probably, had never ſubmitted, during any period of the middle ages, to the laws contained in the codes of the barbarous nations, but were governed entirely by the Roman law. They regulated all their tranſactions by ſuch of its maxims as were preſerved by tradition, or were contained in the Theodoſian code, and other books extant among them. The clergy conſidered it as ſuch a valuable privilege of their order to be governed by the Roman law, that, when any perſon entered into holy orders, it was uſual for him to renounce the laws to which he had been formerly ſubject, and to declare that he now ſubmitted to the Roman law. Beſides, whatever knowledge of ancient juriſprudence had been preſerved, either by tradition or in ſuch books as had eſcaped the deſtructive rage of barbarians, was poſſeſſed only by the clergy. Upon the maxims of that excellent ſyſtem, they founded a code of laws conſonant to the great principles of equity. Being directed by fixed and known rules, the forms of their courts were aſcertained, and their deciſions became uniform and conſiſtent. Nor did they want authority ſufficient to enforce their ſentences. Excommunication, and other eccleſiaſtical cenſures, were puniſhments more formidable than any that civil judges could inflict in ſupport of their decrees. It is not ſurpriſing, then, that eccleſiaſtical juriſprudence ſhould become an object of admiration and reſpect; and that exemption from civil juriſdiction was courted as a privilege, and conferred as a reward. Nor is it ſurpriſing, that even to rude people the maxims of the canon law ſhould appear more equal and juſt than that ill-digeſted juriſprudence which directed all proceedings in the civil courts. According to the latter, the differences between contending barons were terminated by the ſword; according to the former every matter was ſubjected to the deciſion of the laws. The one permitted judicial combats; the other paſſed judgment with reſpect to theſe by the maxims of equity, and the teſtimony of witneſſes. Moreover, the eccleſiaſtical law eſtabliſhed a gradation of courts, through all which a cauſe might be carried by appeal until it was determined by that authority which was held ſupreme in the church. The canon law ſuggeſted other improvements beneficial to ſociety. Many of the regulations, that are now deemed the barriers of perſonal ſecurity, or the ſafeguards of private property, are contrary to the ſpirit, and repugnant to the maxims of the civil juriſprudence, known in Europe during ſeveral centuries, and were borrowed from the rules and practice of the eccleſiaſtical courts. By obſerving the wiſdom and equity of the deciſions in theſe courts men began to perceive the neceſſity either of deſerting the martial tribunals of the barons, or of attempting to reform them. So high in eſtimation was the juriſprudence of the canon law above that which was exerciſed in law-courts, that one of the moſt conſiderable immunities propoſed to thoſe who engaged in the dangerous expeditions for the Holy Land, was the declaring of thoſe who took the croſs to be ſubject only to the ſpiritual courts. Du Cange, Gloſſ. voc. *Crucis Privilegia.* It was not till after the publication of the decretals of Gratian, about the middle of the 12th century, that the canon law attained the rank of a ſcience, and was taught and ſtudied in the ſchools. It ſoon after became the moſt faſhionable ſtudy among the clergy, and paved their way to the higheſt honours and richeſt benefices. About the cloſe of the 12th, or beginning of the 13th century, it was taught with great applauſe and profit at Oxford, Paris, Orleans, and many other places. We may here obſerve, that the compilation of the canon law by Gratian, and the ſubſequent union of the canon law with theology and philoſophy contributed, among other cauſes, to the prevention of the revival of knowledge. Although this compilation was made without judgment, under the authority of Frederic I., it became a body of eccleſiaſtical juriſprudence, which the clergy were required to ſtudy and obſerve. This code was even made an authoritative guide in moral doctrine and diſcipline, and prevented the ſtudy of ethics, till the middle of the 15th century, when the morals of Ariſtotle were again permitted to be read. But the worſt evil was, that they who had framed the unnatural union of canon law, ſcholaſtic philoſophy and theology, finding it exceedingly conducive to their own emolument, reſolutely oppoſed all innovations, and proſcribed with their whole authority all thoſe learned men, who had the boldneſs to attempt further improvements in philoſophy.

The firſt “Syntagma” of canon law was compoſed by John the Scholaſtic, a prieſt of Antioch, in the ſixth century. He is alſo the author of the “Nomo-Canonon.” Both were publiſhed at Paris in Juſtelle's “Bibliotheca Juris Canonici,” tom. ii. In the ninth century, the celebrated Photius compiled his “Syntagma Canonum,” and his “Nomo-Canonon.” The former has not been publiſhed; but the latter was given with a Latin verſion and Balſemon's commentary, by Juſtelle, at Paris, 1615.

The canon law that obtained throughout the Weſt, till the twelfth century, was the collections of canons, “Codex canonum,” compiled by Dionyſius Exiguus, in 520, and publiſhed by Juſtelle in 1628, and improved by Iſidore of Seville, who appropriated them to the diſcipline of Spain; the capitularies of Charlemagne, and the decrees of the popes, from Siricius to Anaſtaſius.—No regard was had to any thing not compriſed in theſe; and the French have ſince maintained the rights of the Gallican church to conſiſt in their not being obliged to admit any thing elſe, but to be at liberty to reject all innovations made in the canonical juriſprudence ſince that compilation, as well as papal decrees before Siricius.

Indeed, between the eighth and eleventh centuries, the canon-law was mixed and confounded with the papal decrees from St. Clement to Siricius; which till then had been unknown: this gave occaſion to a new reform, or body of the canon-law, or harmony of diſcordant canons; which is the collection ſtill extant, under the title of “Concordia Diſcordantium Canonum,” firſt made by Ivo, in 1114, and perfected in 1151, by Gratian, a Benedictine monk, from texts of Scripture, councils, and ſentiments of the fathers, in the ſeveral points of eccleſiaſtical polity; and containing thoſe conſtitutions which have been denominated, by way of eminence, the DECREES, and forming the firſt part of the canon-law. Theſe are the moſt ancient, as they commence from the time of Conſtantine, the firſt Chriſtian emperor of Rome, and they reached as low as the time of pope Alexander III. It is now generally known by the name of the “Decretum” of Gratian, which was formed in imitation of the Pandects of Juſtinian; and is a confuſed immethodical compilation, full of errors and forgeries.

The ſecond part of the canon-law conſiſts of the decrees of the popes, from the time of pope Alexander III. to pope Gregory IX. and publiſhed, under the auſpices of that pope, by Raymundus Barcinius, about the year 1230, in five books, entitled "Decretalia Gregorii Noni."

In 1298, pope Boniface VIII. continued the papal decrees as far as his time, under the title of "Sextus Decretalium." To theſe, pope John XXII. added the "Clementines," or the conſtitutions of his predeceſſor Clement V. approved by the council of Vienne, and firſt authenticated about the year 1317. And to all theſe were afterwards added twenty conſtitutions of the ſaid pope John, called the "Extravagantes;" and ſome other conſtitutions of his ſucceſſors, called "Extravagantes Communes." Theſe are uſually called the DECRETALS.

All theſe, viz. Gratian's decree, Gregory's decretals, the ſixth decretal, the Clementine conſtitutions, and the extravagants of John and his ſucceſſors, form the "Corpus Juris Canonici," or body of the Roman canon-law; which, including the comments, make three volumes, in folio; the rule and meaſure of church government. As the *decrees* ſet out the origin of the canon law, and the rights, dignities, and decrees of eccleſiaſtical perſons, with their manner of election, ordination, &c. ſo the *decretals* contain the law to be uſed in the eccleſiaſtical courts; and the firſt title in every one of them is the title of the bleſſed Trinity, and of the catholic faith, which is followed with conſtitutions and cuſtoms, judgments and determinations in ſuch matters and cauſes as are liable to eccleſiaſtical cognizance, the lives and converſation of the clergy, of matrimony and divorces, inquiſition of criminal matters, purgation, penance, excommunication, &c. But ſome of the titles of the canon-law are now out of uſe, and belong to the common law; and others are introduced, ſuch as trials of wills, baſtardy, defamation, &c. Beſide theſe pontifical collections, which during the times of popery were received as authentic in this iſland, as well as in other parts of Chriſtendom, there is alſo a kind of national canon-law, compoſed of *legatine* and *provincial* conſtitutions, and adapted only to the exigencies of this church and kingdom. See CONSTITUTIONS. At the dawn of the reformation, in the reign of Henry VIII. it was enacted, that the canon-law ſhould be reviewed; and till that review took place, ſuch canons, conſtitutions, ordinances, and ſynodals provincial as had been made, and were not repugnant to the law of the land or the king's prerogative, ſhould ſtill be uſed and executed. The review was propoſed again in the reign of Edward VI. and of queen Elizabeth; but as it was never accompliſhed, the authority of the canon-law in England depends upon the ſtatute of the 25th Henry VIII. c. 19. which was repealed indeed by queen Mary, and again revived and confirmed by 1 Eliz. c. 1.

As to the conſtitutions and canons made in the convocation of the province of Canterbury in 1603, ratified by the king, and ſoon after adopted in the province of York; theſe never obtained a parliamentary confirmation; and it has been therefore adjudged upon the principles of law and the conſtitution, that where they are not merely declaratory of the ancient canon-law, but are introductory of new regulations, they do not bind the laity, however the clergy may regard them. Strange's Rep. 1057.

Lord Hardwicke cites the opinion of Lord Holt, and declares it is not denied by any one, that it is very plain all the clergy are bound by the canons, confirmed merely by the king; but they muſt be confirmed by the parliament to bind the laity. 2 Atk. 605. There are four ſpecies of courts, in which the canon (and civil) laws are permitted, under different reſtrictions, to be uſed. 1. The courts of the archbiſhops and biſhops, and their derivative officers; uſually called in our law courts Chriſtian, or the eccleſiaſtical courts. 2. The military courts, or courts of chivalry. 3. The courts of Admiralty. 4. The courts of the two univerſities. Their reception in general, and the different degrees of their reception in all theſe courts, are grounded entirely upon cuſtom; corroborated with regard to univerſities by act of parliament ratifying thoſe charters, which confirm their cuſtomary laws. Dr. Blackſtone (Com. vol. i. p. 84.) ſubjoins the following remarks, relating to all theſe courts. 1. The courts of common law have the ſuperintendency over theſe courts; to keep them within their juriſdiction, to determine wherein they exceed them, to reſtrain and prohibit ſuch exceſs, and in caſe of contumacy, to puniſh the officer who executes, and in ſome caſes the judge who enforces, the ſentence ſo declared to be illegal. 2. The common law has reſerved to itſelf the expoſition of all ſuch acts of parliament, as concern either the extent of theſe courts or the matters depending before them. And, therefore, if theſe courts either refuſe to allow theſe acts of parliament, or will expound them in any other ſenſe than what the common law puts upon them, the king's courts at Weſtminſter will grant prohibitions to reſtrain and control them. 3. An appeal lies from all theſe courts to the king, in the laſt reſort; which proves, that the juriſdiction exerciſed in them is received from the crown of England, and not from any foreign potentate, or intrinſic authority of their own. From theſe three ſtrong marks and enſigns of ſuperiority, it appears beyond a doubt, that the civil and canon laws, though admitted in ſome caſes by cuſtom in ſome courts, are only ſubordinate, and "leges ſub graviori lege;" and that, thus admitted, reſtrained, altered, new-modelled, and amended, they are by no means with us a diſtinct independent ſpecies of laws, but are inferior branches of the cuſtomary or unwritten laws of England, properly called the king's eccleſiaſtical, the king's military, the king's maritime, or the king's academical laws. See COURT.

CANON *Religioſorum*, in *Eccleſiaſtical Antiquity*, a book in which the religious of convents had a fair tranſcript of the rules of their order, which were frequently read among them as their local ſtatutes; and on this account it was called their "regula," or "canon." The public books of the religious were the four following: 1. "Miſſale," containing all their offices of devotion. 2. "Martyrologium," or a regiſter of their peculiar ſaints and martyrs, with the place and time of their paſſion. 3. "Canon," or "regula," which included the inſtitution and rules of their order. 4. "Necrologium," or "Obituarium," in which they entered the deaths of their founders and benefactors, that they might obſerve the proper days for commemorating them. Kennet's Gloſſ.

CANONARCHA, or CANONARCHUS, a dignity in the Greek church, anſwering to the PRECENTOR in the Latin, or CHANTER in the Engliſh church. The word is formed from κανων and αρχη, *beginning*, or *governing*; becauſe it belongs to this officer to ſet the canons, or church hymns, and to direct the choir in ſinging them. A like officer we alſo find in the ancient monaſteries, under the denomination canonarcha, whoſe buſineſs was to beat the ſemantium, or wooden inſtrument, whereby the monks were called to choir to ſing canons. There appear to have been ſeveral canonarchæ in the ſame monaſtery.

CANONE *al ſoſpiro*, in the Italian *Muſic*, a canon, the parts of which ſucceed each other by a *ſoſpiro*, that is, the time of a crotchet.

**CANONESS**, in the *Romiſh Church*, a woman who enjoys a prebend, affixed, by the foundation, to maids; without their being obliged to renounce the world, or to make any vows. There are few of theſe, except in Flanders and Germany; they are rather looked upon as a ſeminary and retreat of girls for marriage than an engagement for the ſervice of God.

Canonesses *of St. Auguſtine*, or *Regular* Canonesses, are a kind of religious, who follow the rules of St. Auguſtine, of which there are various congregations. The order of canoneſſes was firſt inſtituted by Lewis the Meek, in the beginning of the ninth century.

**CANONGOES**, in *Modern Hiſtory*, a denomination given in Bengal to the regiſters of land, and hereditary expounders of the uſages of the country. They have every where their officers and deputies, and are not liable to removal: and all papers atteſted by them are received as authentic and deciſive in diſputes concerning lands and their boundaries.

**CANONHERIUS**, Peter, Andrew, in *Biography*, the ſon of a phyſician of eminence at Genoa, under whom he received the rudiments of his education, which he completed at Parma, where he applied with equal induſtry to the ſtudy of medicine and juriſprudence. In 1604, probably on his being created doctor in philoſophy, medicine, and theology, he publiſhed at Parma "Concluſiones philoſophicæ et medicæ," 4to. and the ſame year "De admirandis Vini Virtutibus," 8vo. Antwerp; in 1607, "De Curioſa Doctrina Libri quinque," 4to. Florentiæ. But his principal work is, "In ſeptem Aphoriſmorum Hippocratis Libros, medicæ, politicæ, morales, ac theologicæ Interpretationes," Ant. 1618, 2 tom. 4to. But the labour of the author has rather obſcured, than elucidated the texts he meant to explain. Haller Bib. Med. Eloy. Dict. Hiſt.

**CANONICA**, in *Philoſophical Hiſtory*, an appellation given by Epicurus to his doctrine of logic. It was called canonica, as conſiſting of a few canons, or rules, for directing the underſtanding in the purſuit and knowledge of truth: and it is repreſented as a very ſlight and inſufficient logic, by ſeveral ancients who put a great value on his ethics and phyſics. The ſtreſs of Epicurus's canonica conſiſts in his doctrine of the criteria of truth. All queſtions in philoſophy are either concerning words or things: concerning things, we ſeek their truth; concerning words, their ſignification: things are either natural or moral; and the former are either perceived by ſenſe, or by the underſtanding. Hence, according to Epicurus, ariſe three criterions of truth, viz. ſenſe, anticipation or prænotion, and paſſion. The great canon, or principle, of Epicurus's logic is, that the ſenſes are never deceived; and therefore, that every ſenſation, or perception of an appearance, is true. Stanley's Hiſt. Phil. p. xiii. p. 35. See Epicurean *Philoſophy*.

Canonica is alſo uſed by ſome ancients to denote the art of muſic: and it is more particularly uſed to denote that ſpecies of muſic, which does not determine the intervals of ſounds by the ear, but by a canon or ſtretched chord. See Canon.

**CANONICAL**, ſomething that belongs to, or partakes of the nature of a rule or canon: and amounts to much the ſame with what we otherwiſe call regular.

Canonical is an appellation more peculiarly given to thoſe writings which have been received as the rule of our faith and practice, and comprehended in the canon or catalogue of the Scriptures. In which ſenſe, canonical ſtands contradiſtinguiſhed from apocryphal. Divines generally hold, that thoſe books only of the New Teſtament are to be accounted canonical, which were either written, or at leaſt approved and authorized by the apoſtles. Formerly they were not ſo well diſtinguiſhed as among us. In the firſt ages of the church, Dodwell obſerves the genuine writings of the apoſtles uſed to be bound up together with thoſe now called ſpurious, and apocryphal; ſo that it was not manifeſt, by any public judgment, which of them was to be preferred to the other; but later times thought fit to make a ſeparation.

The Jews allow of no books for canonical, but thoſe written before or ſoon after the return from the Babyloniſh captivity, when the gift of prophecy ceaſed among them. In determining the queſtion, what books are canonical, and what are apocryphal, ſome have had recourſe to the authority of the church. Accordingly, the papiſts have generally affirmed, in their controverſies with the proteſtants, that the authority of the Scriptures depends upon, or is derived from the power of the church; or, in other words, that it is in the power of the pope, or council, or both, to determine what books ſhall be received as canonical. Others are of opinion, that there are innate evidences in the Scriptures themſelves, which, applied by the illumination or teſtimony of the Holy Spirit, are the only true proofs of their being canonical, or the word of God. The inſufficiency of theſe two modes of deciſion has been examined and evinced by ſeveral writers, and particularly Mr. Jones, *ubi infra*. The principal, and without doubt, moſt unexceptionable and ſatisfactory method by which this queſtion can be determined, is tradition, or the well-approved teſtimonies of thoſe who lived in, or near the time when the books ſuppoſed to be canonical, were written. To this purpoſe Mr. Jones alleges, that the ſeveral books of the New Teſtament, at their firſt writing, were publiſhed abroad to the world, and delivered to the firſt churches in diſtant countries, for their uſe; and they who firſt received them knew them to be the books of the perſons under whoſe names they were publiſhed, and could, and did teſtify to the ſucceeding ages, what they thus knew of the facts. This teſtimony of the primitive churches is ſtill faithfully preſerved in the writings of the ancient Chriſtians, and is, therefore, not only a good and ſufficient, but the principal means by which we know the truth of the fact, viz. that the books were written by ſuch and ſuch men. Beſides, the books contain in themſelves evidences of their excellency above all others, which ſhould ſerve to confirm our faith; and, for our farther help, we may hope to obtain the influences of God's Holy Spirit, to clear our judgments, and free us from prejudices, to help us to perceive the former evidences in their due ſtrength, and ſo to impreſs the things revealed on our minds, as to produce a ſuitable conduct. Moreover, thoſe books which are mentioned in the catalogues made by the moſt ancient Chriſtian writers of the ſacred and inſpired books, are to be eſteemed canonical, and thoſe which are not found in any of theſe catalogues, muſt be conſidered as apocryphal. And farther, thoſe books are juſtly eſteemed canonical, which the firſt writers of Chriſtianity have cited in their writings as Scripture, and thoſe apocryphal which they have not ſo cited. Beſides, thoſe books are canonical, which the primitive Chriſtians read in their churches, or public aſſemblies, as the Scriptures or word of God. Jones's new and full Method, &c. vol. i. See Canon and Apocryphal.

Canonical, *poſt*, or *deutero*-Canonical. See Canon, and Deutero-*Canonical*.

Canonical is alſo an appellation given to thoſe epiſtles in the New Teſtament, more frequently called catholic, or general epiſtles.

Canonical, *canonicus*, was alſo an appellation given to all the officers and miniſters of a church or monaſtery, from the biſhop or abbot to the meaneſt ſervant, including prieſts, monks, virgins, and all who were entered in canon, that is, in the matricula or regiſter of the church.

Canonical *horſes*, *canonici equi*, was an ancient tax, or tribute, impoſed on certain provinces, whereby they were obliged to furniſh the emperor with ſo many horſes to mount his cavalry.

Canonical *hours*, are certain ſtated times of the day, conſigned, more eſpecially by the Romiſh church, to the offices of prayer and devotion. Such are *matins*, *lauds*, *ſixth*, *ninth*, *veſpers*. In our country the canonical hours are from eight to twelve in the forenoon, before or after which marriage cannot be legally performed in any pariſh-church.

Canonical *inſtitution*, a regular and legitimate collation to a benefice, agreeable to the rules of the canon-law.

Canonical *letters*, in the *Ancient Church*, were a ſort of teſtimonials of the orthodox faith, which the biſhops and clergy ſent each other, to keep up catholic communion, and diſtinguiſh orthodox Chriſtians from Arian, and other heretics. When they had occaſion to travel into other dioceſes, or countries, dimiſſory and recommendatory letters, alſo letters of peace, &c. were ſo many ſpecies of *canonical letters*. See Dimissory.

Canonical *liberty*, a freedom to which certain churches are left, being governed by the ancient canons and uſages eſtabliſhed before the papal hierarchy was carried to its height: ſuch is that which, of later days, the French call the *Gallican liberty*.

Canonical *life*, the method or rule of living preſcribed by the ancient clergy who lived in community. The canonical life was a kind of medium between the monaſtic and clerical lives.

The orders of monks aud clerks were originally diſtinct; but, in proceſs of time, pious perſons inſtituted colleges of prieſts and canons, where clerks, actually engaged in the miniſtry, or admitted for it, might live under a fixed rule, which, though ſomewhat more eaſy than that of the monks, was nevertheleſs more reſtrained than the ſecular. This was called the "canonical life;" and thoſe who embraced it, "canons." Authors are not agreed concerning the founder of the canonical life. Some aſcribe it to the apoſtles; others refer it to pope Urban I. about the year 1230, who is ſaid to have ordered biſhops to provide ſuch of their clergy as were willing to live in community with neceſſaries out of the revenues of their churches. Moſt writers aſcribe it to St. Auguſtine, who, having engaged a number of clerks to devote themſelves to religion, inſtituted a monaſtery within his epiſcopal palace, where he lived in community with them. Onuphrius Panvinius ſays, that pope Gelaſius I., about the year 495, placed ſix regular canons of St. Auguſtine in the Lateran church.

Canonical *obedience*, is that ſubmiſſion which by the eccleſiaſtical laws the inferior clergy are to pay to their biſhops, and religious, to their ſuperiors.

Canonical *portion*, ſo much of the effects of a perſon deceaſed, as the canons allow to the pariſh church to which he belonged.

Canonical *puniſhments* are thoſe which the church may inflict: ſuch are excommunication, degradation, and penance, in Roman catholic countries; alſo faſting, alms, whipping, &c.

Canonical *purgations*, were ancient methods of proving innocency by ordeal, purgation, &c. See alſo Compurgation, Oath, &c.

Canonical *ſins*, in the *Ancient Church*, thoſe which were capital or mortal: ſuch eſpecially were idolatry, adultery, murder, hereſy, and ſchiſm.

CANONICUM, in a general ſenſe, denotes a tax, or tribute.

Canonicum is more particularly uſed in the Greek church for a fee paid by the clergy to biſhops, archbiſhops, and metropolitans, for degrees and promotions.

Canonicum alſo denotes a due of firſt-fruits, paid by the Greek laity to their biſhops, or, according to Du-Cange, to their prieſts. The canonicum is aſſeſſed according to the number of houſes, or chimnies, in a place.

The emperor Iſaac Comnenus made a conſtitution for regulating the canonicum of biſhops, which was confirmed by another made in 1086, by his nephew Alexis Comnenus. A village containing thirty fires, was to pay for its canonicum, one piece of gold, two of ſilver, one ſheep, ſix buſhels of barley, ſix of wheat-flour, ſix meaſures of wine, and thirty hens. Du Cange, Gloſs. Gr. tom. i. p. 578.

CANONIST, a perſon ſkilled in, or who makes profeſſion of, the ſtudy and practice of the canon-*law*.

Canoniſts and civilians are uſually combined in the ſame perſons. And hence the title of *doctor juris utriuſque*, or *legum doctor*, uſually expreſſed in abbreviature, LL. D. or J. U. D.

CANONIUM, in *Ancient Geography*, a place of the iſle of Albion, on the route from Venta Icenorum to Londinium, between Camoladunum and Cæſaromagus, according to Antonine's Itinerary. Mr. Camden has placed this ſtation at Chelmsford, and Dr. Gale hath fixed it at Little Canfield.

CANONIZATION, a declaration of the pope, whereby, after a great deal of ſolemnity, he enters into the liſt of ſaints ſome perſon who has lived an exemplary life, and wrought miracles; or, as is often the caſe, performed ſome ſingular ſervice for the church, in which a principal part of this kind of merit conſiſts. See Beatification.

The word *canonization* ſeems to be of later origin than the thing; there being no inſtance of the uſe of the word before the twelfth century, whereas St. Uldaricus was canonized in the tenth. The term is formed from *canon;* becauſe the primitive canonizations were only orders of the popes, or biſhops, whereby perſons eminent for piety, &c. were inſerted in the canon of the maſs, that they might be commemorated in the ſervice: becauſe, in thoſe days, the uſe of martyrologies was unknown in the church. Mabillon diſtinguiſhes two kinds of canonization; a *general*, and *particular*; the firſt made by a general council, or a pope; the ſecond, by a biſhop, a particular church, or a provincial council. There are inſtances likewiſe of canonizations, or at leaſt of ſomething very like them, by abbots.

At firſt, only martyrs were canonized; but by degrees they came to confeſſors, &c.

Canonization anciently conſiſted in inſerting the ſaint's name in the ſacred diptychs, or canon of ſaints; in appointing a proper office for invoking him, and erecting churches under his invocation, with altars for maſs to be celebrated on; taking up the body from the place of its firſt burial, and the like ceremonies: by degrees, other formalities were added; and proceſſions were made with the ſaint's image in triumph; the day of his death was declared a feaſt; and to render the thing ſtill more ſolemn, Honorius III. in 1225, added ſeveral days indulgence to a canonization.

It is a great diſpute among the learned, when the right of canonization, which it is owned was anciently common to ordinaries, eſpecially metropolitans and princes, with the pope, became firſt peculiar to the pope. Some ſay, Alexander III. made this reſerve to the holy ſee. The Jeſuits of Antwerp, in their Propylæum, aſſert, it was not eſtabliſhed till two or three ages ago; and then by a mere cuſtom, which paſſed tacitly into a law; which appears not to have been generally received in the tenth and eleventh centuries. This, however, is pretty certain, that it was generally allowed before pope Alexander III.; but ſince his time we read of no ſaints canonized by any but the popes, to whom he is ſaid to have reſtricted the privilege and cognizance of canonization: and the archbiſhop of Vienne in France, and his ſuffragans, acknowledge it in an authentic manner in the year 1231, by a letter written to Gregory IX. deſiring him to canonize Stephen, biſhop of Die, who died in 1208. "Quia nemo," ſay they, "quantalibet meritorum prærogativa polleat, ab eccleſia Dei pro ſancto habendus, aut venerandus eſt, niſi prius per ſedem apoſtolicam ejus ſanctitas fuerit approbata."

CANONNICAT, in *Geography*, a ſmall iſland of North America, in Newport county, Rhode iſland, extending ſouth nearly as far as the ſouth end of Rhode iſland, and north about ſeven miles, its average breadth being about one mile; the ſouth ſhore forming the weſt point of Newport harbour, and the weſt ſhore being about three miles from the Narraganſet ſhore. On this point is Jameſtown. It was purchaſed of the Indians in 1657, and in 1678 incorporated by the name of Jameſtown. The ſoil is luxuriant, producing grain and graſs in abundance. Jameſtown contains 507 inhabitants, including 16 ſlaves.

CANONNIERE is a ſmall loophole or opening made in a wall, for firing through with a muſquet or fuſee. Thus canoniere de retranchemens are openings made in the ſoldiers' huts or cabins, for firing through on the enemy. The word is not now in general uſe, that of *craneau* being ſubſtituted in its ſtead. The name of *canoniere*, however, was formerly given to embrazures.

Canonniere is alſo a ſort of tent, in which infantry and cavalry lodge on a campaign. One of them, like a hut or cabin, holds ſeven men. They are of different ſorts and ſizes, according as they are intended for the accommodation of infantry, cavalry, ſuttlers, ſervants, and officers. For a deſcription of their forms or figures, ſee the article Castrametation.

CANONRY, or Canonicate, the benefice filled by a canon. Canonicate is diſtinguiſhed from prebend, in that the prebend may ſubſiſt without the canonicate, whereas the canonicate is inſeparable from the prebend. It is to the canonicate, not to the prebend, that the right of ſuffrages, and other privileges, are annexed. See Prebend.

CANONSBURY, in *Geography*, a town of North America, in Waſhington county, Pennſylvania, pleaſantly ſituated on riſing ground, near the north ſide of the weſt branch of Chartier's creek, 18 miles S.W. from Pittſburg, and 9 miles N.E. from Waſhington. It contains about 100 houſes, and two meeting-houſes, one belonging to the Preſbyterians and the other to the Seceders. Its academy is flouriſhing, and a charter was lately granted in the ſeſſion of the aſſembly for a college. In its vicinity are ſeveral valuable mills.

CANOPICUM, in *Ancient Geography*, a town of Africa Propria, ſituate between the town of Tabraca and the river Bagradas. Pliny ſays, that it was inhabited by Roman citizens. It is the "Canopiſſæ" of Ptolemy.

CANOPUS, in *Aſtronomy*, a bright ſtar of the firſt magnitude in the rudder of Argo, a conſtellation of the ſouthern hemiſphere. See Argo.

The longitude of *Canopus*, as given by Halley, for the year 1700, is 10° 52′ of Cancer, and its ſouthern latitude, 72° 49′. F. Noel, in 1697, found its right aſcenſion 93° 54′, its declination ſouthwards, 52° 29′. F. Feuille, in the beginning of March 1709, obſerved the declination of *canopus* 52° 30′ 4″. F. Thomas, in January 1682, found the declination 52° 31′ 33″, its right aſcenſion 93° 32′ 20″, longitude, 8° 52′, of Cancer, latitude ſouthern, 75° 55′. Wolf. Lex. Math. p. 303, ſeq. Mem. Acad. Scienc. ann. 1693, p. 390, ſeq.

Canopus, is alſo a name given by ſome of the old aſtronomers to a ſtar under the ſecond bend of Eridanus. Theſe writers ſay, that the river in the heavens is not the Eridanus, but the Nile, and that this ſtar commemorates an iſland made by that river, which was called by the ſame name.

Canopus, in *Ancient Geography*, a town of Egypt, ſeated at the diſtance of 120 ſtadia from Alexandria, near the ſea, and at the extremity of the weſtern branch of the Nile, hence called "Oſtium Canopicum," or the Canopic branch. This branch commences near Faoüé or Fouch, croſſes the lake of Behiré or Bahira, and falls into the ſea near the ſcite of Canopus. Near its termination is the lake "Madie" or "Maadiè," denoting in Arabic "paſſage," which is the remains of this branch. This lake is, at preſent, only a ſalt-water lagoon, which has no communication with the Nile, except at the time of its greateſt increaſe. It is paſſed on horſeback, when the overflowing of the river, or a tempeſtuous ſea, has not augmented the depth of the water. In other caſes it is croſſed in a boat, but the paſs is very unſafe and incommodious. The mouth of this ancient branch of the Nile is very narrow, and formed by a bank of ſand. On the eaſtern bank ſtands a large ſquare building, reſembling in its conſtruction that of the French factory at Alexandria, and of all the Caravanſeries in Egypt. Beyond Maadiè towards the ſcite of Canopus, from which the ſea forms an immenſe bight, the ſea-ſhore is ſo low, that it became neceſſary to raiſe ditches or embankments of ſolid conſtruction and of conſiderable extent for keeping out the ſea, which covered a part of the adjacent ground as long ago as the time of Strabo, and which in bad weather ſtill overflows the dykes, extends as far as the promontory of the preſent Aboukir, and inundates a great ſpace of land. Upon theſe dykes ſmall towers are erected at ſome diſtance from each other. The town of Canopus, which is ſaid to have been built by the Lacedæmonians, and which is mentioned by ſeveral ancient writers, as Pliny, Tacitus, Seneca, and Juvenal, &c. was erected upon a rock, forming a handſome road for ſhipping, and elevated above the reach of inundations. Pliny, who collected the teſtimonies of antiquity relating to this place, ſays, that it was formerly an iſland; and the Periplus of Scylax points out a deſert iſland near the Canopic mouth: the local ſituation of Canopus renders this account credible. The remains of this ancient city occupy a vaſt extent of ground, which is ſtrewed with ruins that preſent many objects of admiration to the curious inquirer. The columns of beautiful granite that are found among theſe majeſtic ruins, called by the inhabitants of Aboukir, the city of Pharaoh, are of aſtoniſhing magnitude, and their capitals are of the fineſt workmanſhip; ſome of theſe columns were not long ago ſtanding, together with a large arch that formed the entrance to a ſubterraneous cavern; but they have recently been deſtroyed by the natives for the ſake of the ſtones, which they employed in their buildings and in repairing the dykes that confine the ſea. On the ſea-ſhore are ſtill obſervable, the foundations of a very large, regular building, in the midſt of which is a cavern leading to the ſea, where ruins are to be ſeen at a great diſtance. Blocks of granite of different forms lie ſcattered among theſe remains of antiquity, and in the midſt of theſe occaſionally covered by the ſea, which has made conſiderable encroachments, is a coloſſal ſtatue of a woman, made of granite, fluted through its whole length, and in ſome of its parts mutilated, which the people of the country conceive to have been the figure of Pharaoh's daughter. By the ſide of the ſtatue is a very large ſphinx, partly mutilated, the pedeſtal of which is encircled with hieroglyphics almoſt effaced. The columns of granite with which this place abounds, are probably parts of the magnificent temple, conſecrated to the honour and for the peculiar worſhip of Serapis. Foreigners from the moſt diſtant provinces, but particularly from Alexandria, reſorted hither in crowds, attracted rather by the pleaſures they might enjoy in the city, than for the purpoſe of offering ſacrifices to the god. The prieſts were, indeed, conſulted no leſs as phyſicians, than as interpreters of the oracle, and they were occupied in reciting the marvellous cures that were performed here, the honour of which they attributed to Serapis. We need not wonder that this ſhould be a place of great reſort, when we conſider that the ſurrounding country, inundated by the Nile, was clothed with the riches of nature, and that the city afforded all the enjoyments of luxury in the greateſt profuſion. The attractions of the ſituation, the beauty of the climate, the delicacies of the table, the general affluence of the people, and, in ſhort, the pleaſures of every kind, which ſeemed to have made this their favourite abode; all concurred to make Canopus the moſt enchanting retreat, and to render its inhabitants the happieſt aſſemblage of people.

"Pelæi gens fortunata Canopi,"

ſays Virgil, Georg. l. iv. But diſſipation had here attained its higheſt pitch; licentiouſneſs knew no bounds. Strabo (l. xvii. vol. ii. p. 1153.) informs us, that the canal which paſſed from Alexandria to Canopus was covered night and day with boats, full of men and women, who ſung and danced in the moſt laſcivious manner. To the ſame purpoſe Seneca obſerves, (Epiſt. 51.) that if a ſage wiſhed for retirement, he would not chooſe Canopus as a place of retreat. Juvenal, when he is repreſenting in ſtrong terms, the degree in which the manners of the Romans were corrupted, ſays, that Canopus itſelf condemned them:

"—— Et mores urbis damnante Canopo."

Upon or near the ruins of ancient Canopus, is built the preſent *Aboukir*, called by mariners, "Bekier," which has a caſtle built upon the point of a cape that projects a conſiderable way into the ſea. Some ſhoals ſtretching out beyond the cape encloſe, in a large bay which is here formed by the coaſt, a ſmall harbour, where veſſels lie in ſafety, at the foot of the caſtle, in the front of which is a good roadſtead; this was the uſual anchorage of French frigates, which cruiſed in theſe ſeas. It was alſo frequented by merchant-ſhips, when they were obliged, from bad weather, to quit the new and dangerous port of Alexandria; and likewiſe by the country "germs" when they could not make Alexandria, or clear the "Boghaſs" of the Nile at the mouth of the Roſſetta branch. In this roadſtead the valiant and now (1806), much lamented lord Nelſon obtained his glorious victory over the French fleet. See Aboukir.

Canopus, in *Pagan Mythology*, an Egyptian deity, as ſome have ſuppoſed, whoſe divinity probably originated in a Greek fable. The Greeks were fond of tracing the arts, ſciences, and theological opinions and rites of other nations to a Greek origin. Accordingly they relate, that Menelaus, in his return from Troy, ſtopped to refit his ſhips and refreſh his crew on the coaſt of Egypt, near one of the mouths of the Nile; and that, during his ſtay, Canopus or Canobus, his chief pilot, was bitten by a viper, and fell a victim to this accident. The city of Canopus, they ſay, was erected over his tomb, and derived its name from him. This etymology of Canopus is mentioned by Strabo, *ubi ſupra*. But though Herodotus ſays that Menelaus had been in Egypt, and has taken notice of the city called Canobus, he does not ſay a word of Canobus, or of his death. This Greek fable, however, was repeated in the fourth century by Epiphanius, (Oper. t. ii. p. 10. edit. Petavii.) who has made Canopus a particular deity of the Egyptians. Rufinus alſo has repeated it. (Hiſt. Eccleſ. ii. c. 26.) The Chaldeans, it has been ſaid, who worſhipped fire, carried their fancied deity through many countries, in order to evince his power to be ſuperior to that of other deities; and as he obtained a complete victory over all the other gods of wood, braſs, ſilver, and gold, his dominion was eſtabliſhed, or his claim to worſhip acknowledged. The prieſts of Canopus, when they heard of this triumph, determined to give their deity an opportunity of contending with that of the Chaldeans. They repreſented Canopus under the form of veſſels pierced with a great number of holes, which were ſtopped with wax, in which they were accuſtomed to purify the water of the Nile; and having filled one of theſe veſſels with water, and painted it with different colours, they fitted to its ſurface the head of an idol of human ſhape, and then brought it out to contend with the Chaldæan deity. The Chaldæans accordingly kindled a fire all round it; but when the heat had melted the wax, the water guſhed out through the holes, and extinguiſhed the fire; and thus, it is ſaid, Canopus conquered the god of the Chaldæans. As a proof that ſuch an Egyptian deity as Canopus actually exiſted, it has been alleged, that the geographer, Dionyſius Periegetes, calls the city of Canopus, the celebrated temple of Canobus of Amyclea:

"Καὶ τέμενος περίπυστον Ἀμυκλαίοιο Κανώβου."
"There ſtands Canobus temple known to fame:
"The pilot, who from fair Amycla came."

This paſſage, however juſtly interpreted, affords no evidence that a particular god, called Canobus, had a temple in that city. Homer (Il. B. v. 695.) calls the territory of Pyrrhaſus "the temple of Ceres," becauſe its fields were very fertile in corn. Thus alſo Pindar (Pyth. Od. iv.) calls Lybia and the whole of Egypt, "the fertile temple of the Nile." By a ſimilar metamorphoſis, Dionyſius might have called the city of Canopus, which he believed to have derived its name from the Mauſoleum of Canobus, "the temple of the pilot of Amyclea". The temple of Canopus was that of Serapis; and this deity was worſhipped in other countries beſides Egypt, under the appellation or diſtinction of Serapis of Canopus. The ſingular form under which Serapis was worſhipped at Canopus will ſerve to lead us into an acquaintance with the nature and attributes of this deity, which were different from thoſe of the Serapis or Pluton, brought by the Greeks to Alexandria. This was a bottle, or veſſel, as we have above mentioned, made of a very precious clay, which ſerved to filter the water of the Nile, or to render it clear and fit for drinking. The inhabitants of Canopus found this clay in their neighbourhood, and they carried on through Egypt an extenſive commerce in theſe filtrating veſſels. The medals of Canopus, ſtruck in honour of Adrian, preſent one of theſe vaſes ſurmounted with a ſerpent, which was, without doubt, the good genius, αγαθος Δαιμων. This name of good genius had been given to the branch of the Nile which flowed near Canopus. Hence we may conclude, that the great divinity of the

Canopians was the good genius of the Nile, and that it was repreſented by a filtrating veſſel; but this god of the Nile, which purſued its courſe in the Canopic branch, was transformed by the Greeks into Serapis. Accordingly they worſhipped at Alexandria Serapis-Pluton, and at Canopus, Serapis of the Nile. Many Egyptian vaſes, called "Canopes," are preſerved in the collections of Antiques; ſome of which may reaſonably be ſuppoſed to repreſent the Serapis of the Nile.

CANOPY, in *Architecture* and *Sculpture*, a magnificent kind of decoration, ſerving to cover, and crown an altar, throne, tribunal, pulpit, chair, or the like. See BALDACHIN.

The word is formed from the barbarous Latin *canopeum*, of κωνωπεῖον, *a net ſpread over a bed to keep off the gnats*, from κώνωψ, *a gnat.*

Canopies are alſo borne over the head in proceſſions of ſtate, after the manner of umbrellas.

The canopy of an altar is more peculiarly called CIBORIUM.

The Roman grandees had their canopies, or ſpread veils, called *thenſæ*, over their chairs: the like were alſo in temples over the ſtatues of the gods. The modern cardinals ſtill retain the uſe of canopies. The canopy, as we render κωνωπεῖον (Judith xiii. 9.) ſhould, as Dr. Shaw ſuggeſts (Travels, p. 221), rather be called the gnat, or muſquetoe net, which is a cloſe curtain of gauze or fine linen, uſed, all over the Eaſt, by people of better faſhion to keep out the flies.

CANORASAY, in *Geography*, a ſmall iſland of Scotland, near the eaſt-coaſt of the iſland of Coll.

CANOSA, a town of Italy, in the kingdom of Naples, and country of Bari, deſtroyed by an earthquake in 1694. It was once epiſcopal, but the ſee has been united to the archbiſhopric of Bari: 31 miles weſt of Bari. This town occupies part of the ſcite of the ancient Canuſium founded by Diomed, and afterwards a Roman colony, which became one of the moſt conſiderable cities in this part of Italy for extent, population, and magnificent buildings. The æra of Trajan ſeems to have been that of its greateſt ſplendour; but it was thus marked as an object alluring to the avarice and fury of the barbarians. Genſeric, Totila, and Autharis treated it with extreme cruelty. The province to which it belongs was reduced to a deplorable ſtate in 590. No town in Puglia ſuffered more than Canoſa from the outrages of the Saracens; and the meaſure of its diſtreſs was much augmented by the conteſts between the Greeks and Normans. In 1090, it was aſſigned, by agreement, to Bohemund, prince of Antioch, who died here in 1111. Under the reign of Ferdinand III. this eſtate belonged to the Grimaldis; but on their forfeiture, the Affaititi regained it, and ſtill retain the title of Marquis, though the Capeci are the proprietors of the fief. The ancient city ſtood in a plain between the hills and the river Ofanto, and covered a large tract of ground. Its ancient grandeur is ſtill atteſted by many fragments of aqueducts, tombs, amphitheatres, baths, military columns, and two triumphal arches, which ſeem to have been two city gates. The preſent town ſtands above, on the foundation of the old citadel, and is a poor remnant of ſo great a city, not containing above 300 houſes. The church of Sabinus, built, as it is ſaid, in the 6th century, has altars and pavements that are rich in marbles, and the ſix Verde Antico columns that ſupport its roof are the largeſt and fineſt, ſays Swinburne, which he ever ſaw of that ſpecies of marble. In a ſmall adjoining court, under an octagonal cupola, is the mauſoleum of Bohemund, adorned in a minute Gothic ſtyle. In 1461, the prince of Taranto, among other acts of barbarity practiſed by him at Canoſa, broke open this ſepulchre, and diſturbed the aſhes of a hero, who, by his extraordinary military talents, rivalled the fame of his father Guiſcard, and by his victories ſhook the throne of the eaſtern emperors; and when he was deprived of his Italian inheritance, turned his arms againſt the Saracens, and formed a new ſovereignty for himſelf in Paleſtine. As prince of Antioch, he became one of the firmeſt ramparts of the Cruſado againſt the infidels. Swinburne's Travels, vol. ii. p. 321.

CANOSA, in *Ichthyology*, a name given by Salvian, and ſome other authors to the ſpecies of SHARK, called by modern writers *ſqualus galeus*, the tope of the Corniſh fiſhermen.

CANOSIA, in *Geography*, a town of Piedmont, in the marquiſate of Saluzzo; 15 miles S.W. of Saluzzo.

CANOT *Cape*, lies on the eaſt ſide of the iſland of St. Lucia, in the Weſt Indies, towards the north end of the iſland. On its ſouth ſide is a bay of the ſame name.

CANOUGE. See CANOGE.

CANOVIO, a town of European Turkey, in the province of Albania; 22 miles S. of Durazzo.

CANOUL, a town of Hindooſtan, and capital of a circar, in the country of Hydrabad; 95 miles S S.W. of Hydrabad, and 124 E. of Biſnagur. N. lat. 16° 10′. E. long. 78° 7′.

CANOURGUE, LA, a town of France, in the department of the Lozere, and chief place of a canton, in the diſtrict of Marvejols. The town contains 2419, and the canton 6430 inhabitants; the territory includes 238 kiliometres and 7 communes. It is a place of conſiderable trade in cattle and woollen ſtuffs.

CANQUES, in *Commerce*, a ſort of cotton cloth made in China; with this cloth they make that firſt garment next their ſkin, which is properly their ſhirt.

CANRENA, in *Conchology*, a ſpecies of NERITA, that inhabits the Indian, African, and American ſeas, and of which there are nearly thirty varieties at preſent aſcertained. It is ſpecifically diſtinguiſhed by the ſhell, ſmooth, with a ſomewhat pointed ſpire, and bifid, gibbous, umbilicus, Linn.—*Obſ.* There is much reaſon to believe that ſome at leaſt of thoſe ſhells which Gmelin conſiders as varieties only of his *nerita canrena*, may prove, on further examination, to be diſtinct ſpecies.

CANSADO *Cape*, in *Geography*, is ſituated three leagues N.N.E. from Cape Blanco, on the coaſt of Africa.

CANSCHI, in *Botany*, (Rheed. Mal. i. tab. 42. Burm. Ind. 298.) See TREVIA *Nudiflora.*

CANSCHY, a large tree in Japan, from which the inhabitants make their paper. See a particular account of the proceſs from the Ephem. N. C. in the Coll. Acad. P. Etr. tom. iv. p. 144. It is not certainly known whether it be the paper mulberry, *morus papyrifera*, Linn. *papyrius*, Lam. *browſonnetia*, L'Herit. and Ventenat.

CANSJERA. Juſſ. 448. (Tſierou Cansjeram. Rheed. vii. tab. 2. Claſs and order, *pentandria monogynia.* Nat. Ord. *Thymeleæ*, Juſſ.

Gen. Char. *Calyx* globular-pitcher-ſhaped, four-toothed. *Corolla* none. *Stam.* filaments four, inſerted into the bottom of the calyx; anthers roundiſh, not extending beyond the calyx. *Piſt.* germ ſuperior, very ſmall, encloſed by four ſcales; ſtyle one; ſtigma capitate. *Peric.* berry one-ſeeded. A ſhrub. *Leaves* alternate. *Flowers* with one bracte, in axillary ſpikes. Character formed from a dried ſpecimen of Sonnerat's communicated by La Marck, except the fruit, which is taken from Rheede's figure.

CANSO, CANCEU, or CANCO, in *Geography*, an iſland, cape, and ſmall fiſhing-bank on the S.E. coaſt of Nova Scotia, about 40 leagues E. by N. from Halifax. The iſland is ſmall, and near the continent, N.E. from Cape Canſo, which is the ſouth-eaſternmoſt land of Nova Scotia. Canſo has a good harbour, about three leagues deep. Here are two bays of ſafe anchorage. Near theſe, on the continent, is a river, called Salmon river, on account of the great quantity of ſalmon taken and cured there. This is thought to be the beſt fiſhery of that ſort in the world. Limeſtone and gypſum are found in the gut of Canſo, which is a very narrow ſtrait, forming the paſſage from the Atlantic into the gulf of St. Lawrence, between Cape Breton and Nova Scotia.

Canso *Port*, of which the ſouth point is Cape Canſo, is ſituated in N. lat. 45° 20′ 7″. W. long. 60° 55′.

Canso is alſo a townſhip near the above-named place, in the county of Halifax.

CANSTADT, a town of Germany, in the circle of Swabia, and duchy of Wirtemberg, ſeated on the eaſt bank of the Neckar. In the town is a manufacture of printed linens, and near it are medicinal ſprings. It is diſtant three miles N.E. from Stuttgart. N. lat. 48° 51′. E. long. 7° 9′.

CANSTEIN, a town and citadel of Germany, in the circle of the Lower Rhine, and duchy of Weſtphalia; 6 miles S.E. of Stadtburg.

CANSTRISIUS, an officer in the church of Conſtantinople, whoſe buſineſs is to take care of the patriarch's pontifical veſtments, aſſiſt in robing him, and during maſs to hold the incenſe-pot, and ſprinkle holy water among the people, while the hymn of the Trinity is ſinging. The word is alſo written *Canſtrinſius*; it is uſually derived from *caniſtrum*, a name which ſome ſuppoſe given to the incenſe-pot, others to the kind of baſket in which the patriarch's veſtments were kept. Du-Cange.

CANSWA, in *Geography*, a river of Hindooſtan, which runs into the ſea, 40 miles S.S.W. of Junagur or Chunagur, in the country of Guzerat.

CANT, a quaint, affected manner of ſpeaking, or writing, adapted chiefly to the lower ſort.

Cant is originally derived from *Andrew Cant*, a Cameronian preacher in Scotland, who, by exerciſe, had obtained the faculty of talking in the pulpit in ſuch a tone and dialect as was underſtood by none but his own congregation; and hence the term is extended to denote all ſudden exclamations, and whining tones, eſpecially in praying and preaching. This origin of the word, however, has been diſputed, and it has been derived from the Latin *cantare*, to ſing. Others imagine that it is corrupted from *quaint*, of Fr. *coint*, and Lat. *comptus*.

Cant, or *Canting Language*, is alſo applied to words and phraſes affected by particular perſons, or profeſſions, for low ends, and not authorized by the eſtabliſhed language. Cant is not reſtrained to the ſtyle of gypſies, thieves, and beggars, but poſſeſſes a large department in the politer provinces of the Engliſh language. An anonymous author has given a *canting* dictionary, comprehending all the terms uſed in the ſeveral tribes of gypſies, beggars, ſhoplifters, highwaymen, foot-pads, and other clans of cheats and villains, with a collection of ſongs in the *canting* dialect. Lond. 1725, 8vo. A writer in the Tatler, aſſigns divers ſources of cant-words; as *phizz*, *hippo*, *mobb*, *pozz*, *bamm*, *&c.* Tatl. N° 230.

The ſea-language will moſt of it come under the denomination of cant; and the like holds of the terms in alchemy, heraldry, not to ſay in aſtrology, or even chemiſtry, pharmacy, &c. In reality the difference between a cant-term, and a technical term it is not eaſy to aſſign, unleſs we chooſe to reſtrain the former to words introduced out of folly, affectation, or impoſture; and the latter to ſuch as are introduced for the ſake of clearneſs, preciſion, and ſignificancy.

Cant is alſo uſed to denote a ſale by auction.

The origin of the word, in this ſenſe, is dubious; it may come, according to ſome, from *quantum*, how much; according to others, from *cantare*, to ſing, or cry aloud; agreeably to which, we ſometimes alſo call it an *out-cry*.

Cant-*timbers*, in *Ship-Building*, are thoſe timbers which are ſtationed near the two ends of a ſhip. They are ſo called becauſe their planes are inclined to the middle vertical ſection of the ſhip lengthwiſe, or plane of elevation, in contradiſtinction to thoſe whoſe planes are perpendicular thereto. And this *canting*, or *inclination* of any timber is ſuch, that it may ſtand perpendicular, or nearly ſo, to that part of the ſhip's ſide where the timber is ſtationed.

Cant is alſo popularly uſed for an angle, or corner: and cant-pieces are thoſe that are uſed in the angles of the fiſhes, and ſide-trees; or to ſupply any part that may be ſappy or rotten.

Cant, Arent, in *Biography*, aſſiſted Ruyſch, towards the end of his life, in making his anatomical preparations. He was afterwards a pupil to Albinus, and diſtinguiſhed for his abilities, but died at a very early age. He left a well-furniſhed library, abounding particularly in works on anatomy. In 1721, he publiſhed "Impetus primi anatomicè ex luſtratis cadaveribus nati," fol. Leid. with ſix engraved plates repreſenting the muſcles of the face, the carotid artery, dura mater, the heart in ſitu, the ſtomach, and joint of the knee, in general correctly delineated. Haller Bib. Anat.

CANTA, in *Geography*, a juriſdiction of South America, in the vice-royalty of Peru, and circuit of Lima. It begins at the diſtance of 5 leagues N.N.E. from Lima, where it terminates in the circado or circuit of that city. Its extent is above 30 leagues, moſt of which comprehend the firſt branch of the Cordillera of the Andes, ſo that the temperature varies in different parts of the country, and is thus beneficial to the fruits of the earth and paſtures; and as every ſpecies may be appropriated to its ſuitable degree of heat, the produce is large and very good. The papa is particularly diſtinguiſhed among the fruits, and the roots find a good market at Lima. The extenſive fields of Bombon, which partly belong to this juriſdiction, though cold from their high ſituation, afford paſture for innumerable flocks of ſheep: they are divided into "Haciendas," or eſtates belonging to noble families of Lima.

CANTABILE, an Ital. *adj.* implying *muſic* fit to be ſung; a melody for the voice, not inſtrumental. A ſeries of meaſured ſounds, of which the *cantilena* is graceful or pathetic, is ſaid to *ſing*. To be able to play or ſing an *aria di cantabile*, is the higheſt praiſe that can be beſtowed on a muſician. Execution ſurpriſes, and for a certain time amuſes; but goes no farther than the ear; but to ſing a cantabile with tenderneſs and expreſſion, is conveying ſounds to the heart.

CANTABRA, in *Ancient Geography*, a river of India, reckoned by Pliny among the moſt conſiderable which diſcharged themſelves into the Indus.

CANTABRI, a people of Hiſpania Citerior, or Hither Spain, or Provincia Tarraconenſis; whoſe diſtrict was bounded on the north by the ſea of their name, "Oceanus Cantabricus," now called the bay of Biſcay; and extended from the country of the Aſturii, on the weſt, to that of the Vaſconi, on the eaſt. Pliny divides them into four nations, without diſtinctly naming them. The Cantabrians inhabited a mountainous country, and were, in their diſpoſition and habits, ferocious and warlike. The women were no leſs valiant than the men; and devoted themſelves to ſimilar employments. Strabo mentions ſeveral facts, evincing the facility with which the females delivered themſelves of their children, without requiring any temporary confinement, or any intermiſſion of their uſual occupations. He alſo informs us, that they endured the ſevereſt tortures without betraying any concern, and chanted their ſongs even at the moment of their dying. It was with great difficulty that the Romans ſubdued this hardy and valiant people. They, as well as the Aſturians (ſee Asturia), defended themſelves for a conſiderable time with invincible firmneſs and reſolution; availing themſelves of the places of ſecure and inacceſſible retreat which their mountains afforded them. They were, however, at length overpowered, and conſtrained to ſubmit to the arms of Auguſtus, about 25 years before Chriſt. Antiſtius, Furnius, and Agrippa were employed in this ſervice; and after having been driven from their towns, and purſued even to their rugged mountains, whilſt the Roman fleet haraſſed their coaſts, they were obliged to ſhelter in mount Medullius, and were ſo ſurrounded, that they had no poſſible means of making their eſcape. When this ſtubborn people found themſelves thus encompaſſed, they preferred a voluntary death to ſurrender and captivity. Moſt of them deſtroyed themſelves by the ſword, by fire, or by a poiſon extracted from the yew-tree, or from an herb reſembling parſley, which they preſerved as a reſource againſt any reverſe of fate, becauſe it made them die without pain. Mothers ſmothered their children, to prevent their falling into the hands of the enemy; and among thoſe who were taken, a young boy was obſerved, who, having found a ſword, killed his brothers, and all his relations, by the order of his father. In like manner, a woman killed all that were priſoners with her. At laſt, when Auguſtus had ſucceeded in ſubduing them, he determined to ſoften their ferocity, by compelling them to abandon their mountains; having ſold ſome of the priſoners, he required hoſtages from thoſe that remained in the country, and fixed their abode in the plains. Impatient of a foreign yoke, they took advantage of the abſence of Auguſtus; they again revolted, and attacked the Roman garriſons with their uſual fury. Agrippa was therefore deputed to complete their reduction, but he found the enterpriſe extremely difficult, ſo that even the Roman ſoldiers under his command began to deſpair of ever accompliſhing it. This brave commander, ſo much were his legionaries diſheartened by the reſiſtance and repulſes with which they had to encounter, was under a neceſſity of recurring to intreaties and menaces, and of puniſhing ſome of his ſoldiers with ignominy, before he could induce them to renew their engagement with this formidable enemy. But having at laſt prevailed upon them to meet the Barbarians in an open field, he ſo animated them by his example, that, after an obſtinate conflict, he obtained a complete victory, and thus terminated this deſtructive war. Having put to death thoſe who were able to bear arms, and deſtroyed their caſtles and ſtrong holds, and forced thoſe who ſurvived to quit their mountains, and to ſettle in the plain, he ſubdued them ſo effectually, that they never attempted to revolt again, but quietly ſubmitted to the Roman yoke. Strabo, lib. iii. Sueton. in Auguſt.

The celebrity of the valorous Cantabrians was formerly ſo great, that moſt of the provinces of Spain laid claim to the honour of having been comprehended within the limits of ancient Cantabria. Louis XV. created or formed a regiment of this name, the 15th December 1745, which, by an ordonnance of the 1ſt of July 1747, was called Royal *Cantabre*. Silius Italicus, in his enumeration of the different tribes, people, or nations, whom Hannibal carried with him into Italy, makes the Cantabrians march before all the reſt. And Pompey regarded the Cantabrians, and ſome cohorts of the neighbouring people, as the beſt troops in his army.

Cantabria, the name of a country on the northen coaſt of Spain, called by the inhabitants Viſcara, and by others Biſcay, and comprehending the provinces of Biſcay, Alava, and Guipuſcoa. See the preceding article. Strabo ſays, (lib. iii. vol. i. p. 237.) that, according to the report of ſome writers, the Lacedæmonians had once poſſeſſed part of this country, and built in it a city called "Opſicella." The Goths having invaded Spain, in the 5th century, Leuvigeld reſolved to ſubdue that part of it which remained ſteadily attached to the Romans, and turning his arms againſt the Cantabrians, took and deſtroyed the city of Cantabria, ſituate between Logronno and Viana, and the city of Amaya. But there he terminated his career; afraid to run the riſk of penetrating farther among the mountains and defiles inhabited by thoſe people, who, in ſpite of him, continued faithful to the Romans, though they were entirely expelled from Spain.

CANTABRIAN, the ancient language of the north-eaſtern part of Spain, in uſe before the country was ſubdued by the Romans. Dr. Wallis ſeems to make the Cantabrian the ancient language of all Spain: which, according to him, like the Gauliſh, gave way to a kind of broken Latin called *romance*, or *romanſhe*; which by degrees was refined into the Caſtilian or preſent Spaniſh. But we can hardly ſuppoſe, that ſo large a country, inhabited by ſuch a variety of people, ſpoke all the ſame language. The ancient Cantabrian, in effect, is ſtill found to ſubſiſt in the more barren and mountainous parts of the province of Biſcay, Aſturias, and Navarre, as far as Bayonne, as much as the Britiſh does in Wales; but the people only talk it: for writing, they uſe either the Spaniſh or French, as they happen to live under the one or the other nation. Some attribute this to a jealouſy of foreigners learning the myſteries of their language; others to a poverty of words and expreſſions. The Cantabrian does not appear to have any affinity with any other known language, abating that ſome Spaniſh words have been adopted in it for things whoſe uſe the Biſcayans were anciently unacquainted with. Its pronunciation is not diſagreeable.

The Lord's prayer, in the Cantabrian tongue, runs thus: *Gure aita cervetan aicena, ſanctifica bedi hire icena, ethor bedi hire reſuma, eguin bedi hire vorondatea cervan becala lurrean ere*, &c.

CANTABRICA, in *Botany* (Cluſ. Hiſt. 2. 49.). See Convolvulus *cantabrica*.

CANTABRUM, in *Antiquity*. Under the Roman emperors, ſucceeding Conſtantine, this was a kind of banner, enſign, or ſtandard, differing in this reſpect from the vexillum, that the latter of theſe was a large flag, diſtinguiſhed by its colour, and by a device on it; whereas the former, or cantabrum, was only a ſmall ſtandard and flag, which had alſo a particular colour, and ſerved for rallying and encouraging the ſoldiers. For this purpoſe it is ſaid to have borne on it ſome words or motto of good omen. Minucius Felix and Tertullian mention it in their apologies, and compare it to a croſs.

CANTACUZENUS, Johannes, in *Biography*, emperor of Conſtantinople and a learned hiſtorian, was born of an ancient and noble family at Conſtantinople, about the year 1295; and having been bred both to literature and to arms, he attained the higheſt offices of the ſtate, ſuch as prefect of the bedchamber under Andronicus the Elder, and the dignity of domeſtic under Andronicus the Younger. Attaching himſelf to the intereſt of Andronicus the Younger, in oppoſition to that of his grandfather Andronicus the Elder, who abdicated the government A.D. 1328, and having contributed to reſcue him from the power of his grandfather, he brought him back in triumph to the palace of Conſtantinople, after ſix years of civil war. Under his reign Cantacuzene ruled both the emperor and the empire; and it was by his valour and conduct that the iſle of Leſbos and the principality of Ætolia were reſtored to their ancient allegiance. Although he enjoyed many favourable opportunities for enriching himſelf by oppreſſion and rapine, his enemies confeſs that, among the public robbers of the empire, Cantacuzene alone was moderate and abſtemious. Nevertheleſs, his wealth, probably devolved upon him by inheritance, appears from his own account of it to have been prodigious; more eſpecially when we conſider that it was partly accumulated in the laſt period of the empire, and in a land, moſt probably in Thrace, ſo repeatedly waſted by foreign and domeſtic hoſtility. He does not indeed ſpecify the value of his money, plate, and jewels; yet, after ſeveral very conſiderable deductions, his forfeit treaſures were ſufficient for the equipment of a fleet of 70 gallies. He does not give us either the extent or number of his eſtates; but his granaries were filled with an incredible ſtore of wheat and barley; and the labour of a thouſand yoke of oxen might cultivate, according to the practice of antiquity, about 62,500 acres of arable land. His paſtures were ſtocked with 2500 brood mares, 200 camels, 300 mules, 500 aſſes, 5000 horned cattle, 50,000 hogs, and 70,000 ſheep. Thus diſtinguiſhed by rural opulence, he enjoyed, in a very high degree, the favour of his ſovereign; and though he declined accepting the honour that was offered him of being his aſſociate in the ſovereignty, he was named in the laſt teſtament of Andronicus the Younger the guardian of his ſon John Palæologus, who ſucceeded his father in the ninth year of his age, A.D. 1341, and the regent of the empire during his minority. This truſt he diſcharged with fidelity, till a regard to his own ſafety rendered it neceſſary for him to adopt meaſures of ſelf-defence. A combination, however, was formed againſt his regency by the dowager empreſs, Anne of Savoy, the great duke or admiral Apocaucus, and John of Apri, patriarch of Conſtantinople. By this powerful confederacy Cantacuzene was aſſaulted at firſt with clandeſtine, and at length with open, arms. During his abſence on the public ſervice he was accuſed of treaſon; proſcribed as an enemy of the church and ſtate; and delivered, with all his adherents, to the ſword of juſtice, the vengeance of the people, and the power of the devil. His fortunes were confiſcated, his aged mother was caſt into priſon, all his paſt ſervices were buried in oblivion, and he was driven by injuſtice to perpetrate the crime of which he was accuſed. As long as the empreſs and the patriarch affected the appearances of harmony, he repeatedly ſolicited the permiſſion of retiring to a private, and even a monaſtic, life; and after he had been declared a public enemy, it was his fervent wiſh to throw himſelf at the feet of the young emperor, and to receive without a murmur the ſtroke of the executioner. At length he reluctantly adopted the only meaſure that was likely to avail to his ſecurity, which was that of drawing the ſword and aſſuming the imperial title. Accordingly in the ſtrong city of Demotica, his peculiar domain, he aſſumed the purple, A.D. 1341; maintaining, even in this act of revolt, ſome ſhew of loyalty, by cauſing to be proclaimed the titles of John Palæologus and Anne of Savoy before his own name and that of his wife Irene. Conſtantinople adhered to the young emperor, and the principal cities of Thrace and Macedonia renounced their obedience to Cantacuzene. His army, which was ſtationed in ſix diviſions on the banks of the Melas, for the purpoſe of tempting or intimidating the capital, was diſperſed by treachery or fear; and the officers accepted the bribes, and embraced the ſervice, of the Byzantine court. Cantacuzene, driven by Apocaucus from the coaſt into the mountains of Servja, his truſty band of followers was diminiſhed to 2000, and at laſt to 500, volunteers. The "Cral," or deſpot of the Servians, received him with hoſpitality; but in a ſtate of miſerable dependence, he in vain ſolicited aſſiſtance, and was at length diſmiſſed, without injury, to a new viciſſitude of hopes and perils. A civil war commenced, which, after having raged for nearly ſix years, terminated in a deciſive victory on the part of Cantacuzene, who re-entered Conſtantinople A.D. 1347. The inflexible Anne, deſtitute of the powers of reſiſtance, or the hope of relief, was at length compelled to yield to the ſupplications of her friends and enemies; and a treaty was dictated by the conqueror, who profeſſed a loyal and zealous attachment to the ſon of his benefactor. The marriage of his daughter Helen with John Palæologus, to whom ſhe had been for ſome time engaged, was at length conſummated; the hereditary right of the pupil was acknowledged; but the ſole adminiſtration, during ten years, was veſted in the guardian. Thus two emperors and three empreſſes were ſeated on the throne; a general amneſty was proclaimed; and the feſtival of the coronation and nuptials was celebrated with fallacious appearances both of concord and magnificence. The tranquillity of Cantacuzene and of the empire was, however, ſoon diſturbed by ſuſpicions and enmities between the two emperors and their reſpective adherents, which at length broke out in a civil war, A.D. 1353. Cantacuzene, aided by the Turks, was ſucceſsful, and the young emperor was compelled to take ſhelter among the Latins of the iſle of Tenedos. The victor, provoked by his inſolence and obſtinacy, was induced to aſſociate with himſelf his ſon Matthew, whom he inveſted with the purple, and thus he eſtabliſhed the ſucceſſion in the family of the Cantacuzeni. Palæologus, however, aſſiſted by the Genoeſe, who, by a treaty ſubſcribed by Cantacuzene, A.D. 1352, which for ever baniſhed the Venetians and Catalans, obtained a monopoly of trade, and almoſt a right of dominion, regained Conſtantinople, A.D. 1355; and Cantacuzene abdicated his ſhare of the government, and retired to a monaſtery, where, under the aſſumed name of Joaſaph and the habit of a monk, he devoted the reſidue of his life to literary and theological exerciſes. His wife Irene alſo retired to a nunnery, and exchanged her own name for that of Eugenia. If, indeed, he iſſued from this retreat, it was as the miniſter of peace, to ſubdue the obſtinacy and ſolicit the pardon of his rebellious ſon. In the retirement of a cloyſter his active ſpirit prompted him to engage in a controverſy againſt the Jews and the Mahometans, and he compoſed four apologies for the Chriſtian religion and four diſcourſes or books, (printed in Greek and Latin at Baſil, in 1543, by Bibliander and Gualtherus, from Greek MSS.) at the particular requeſt of a proſelyte to Chriſtianity, Achæmenides, called alſo Meletius, who was aſſaulted with letters from his friends at Iſpahan. Maracci informs us, that, though he had read the Koran, he adopts the vulgar prejudices and fables againſt Mahomet and his religion. He alſo, with equal zeal, defended the divine light of mount Thabor; and under the character of emperor and theologian, he preſided in the ſynod of the Greek church, which eſtabliſhed, as an article of faith, this uncreated light. See the article Barlaam. In his retirement he alſo wrote a hiſtory of his own times in four books, or at leaſt of thoſe times during which he was a principal actor, comprehending a period that extends from the revolt of the younger Andronicus, A. D. 1320, to his own abdication of the empire, A.D. 1355, and continued one year beyond the abdication of his ſon Matthew, A. D. 1357. "In this eloquent work," ſays Gibbon, "we ſhould vainly ſeek the ſincerity of an hero or a penitent. Retired in a cloyſter from the vices and paſſions of the world, he preſents not a confeſſion, but an apology, of the life of an ambitious ſtateſman. Inſtead of unfolding the true counſels and characters of men, he diſplays the ſmooth and ſpecious ſurface of events, highly varniſhed with his own praiſes and thoſe of his friends. Their motives are always pure; their ends always legitimate; they conſpire and rebel without any views of intereſt; and the violence which they inflict or ſuffer is celebrated as the ſpontaneous effect of reaſon and virtue." Voſſius, however, without heſitation, prefers him to all the Byzantine hiſtorians. A Latin tranſlation of this hiſtory, from the Greek MS. in the library of the duke of Bavaria, with notes, was publiſhed by Pontanus at Ingolſtadt in 1603, fol.; and at Paris in 1645, in a ſplendid edition conſiſting of 3 volumes, fol. of the Greek from the MS. of M. Seguier, chancellor of France, with Pontanus's Latin verſions, and the notes both of Pontanus and Gretſer. Some other treatiſes by Cantacuzene, who aſſumed the name of Chriſtodulus the monk, are extant in MS. in the Vatican, Pariſian, Cæſarean, and Bodleian libraries. The death of Cantacuzene is placed by reſpectable authority on the 20th of November 1411. (Du-Cange, Fam. Byzant. p. 260.) But if he were of the age of his companion Andronicus the Younger, he muſt have lived 116 years; a rare inſtance of longevity, which, in ſo illuſtrious a perſon, would have attracted univerſal notice. Fabr. Bib. Græc. t. vi. l. v. c. 5. §. 12. p. 469, &c. Gibbon's Hiſtory, &c. vol. xi.

**CANTADUANES**, in *Geography*. See CATANDUANES.

**CANTÆ**, in *Ancient Geography*, a people of Britain in that part called Caledonia, who, according to Ptolemy, were ſeated towards the eaſtern coaſt on the north ſide of the frith of Tayne. Mr. Baxter places them in Buchan, which he derives from the Britiſh words "Pow Chant," ſignifying, as he ſays, the country of the Cantæ.

**CANTAL**, in *Geography*, a large and lofty mountain of France, which is ſaid to be 993 toiſes higher than the level of the ſea, and always covered with ſnow. It is ſituated in the centre of a department to which it gives name, and which is one of the three formed out of Auvergne and le Velay. This department is bounded on the north by the departments of Upper Loire, Puy de Dôme, and Corrèze; on the eaſt by thoſe of Upper Loire and Lozère; on the ſouth by thoſe of Lozère, Aveyron, and Lot; and on the weſt by thoſe of Lot and Corrèze. Its ſuperficies is about 1,124,802 acres, or 574,081 hectares; its population conſiſts of about 243,708 perſons; and it is divided into four communal diſtricts, viz. Mauriac, Murat, St. Flour, and Aurillac.

**CANTALIVER**, in *Architecture*. This term is uſed by workmen to denote thoſe blocks which are frequently placed, at regular diſtances, under the eaves of a houſe, or the upper mouldings of a cornice, which they ſerve to ſupport or ornament. Cantaliver, therefore, is eſſentially the ſame with modillion; but the latter word is confined to the deſcription of regular architecture, while the former has a general and trivial uſe.

**CANTANUS**, in *Ancient Geography*, a town placed by Steph. Byz. in the iſland of Crete. It was an epiſcopal ſee, and mentioned in the acts of the council of Chalcedon.

**CANTAR**, or CANTARO, in *Commerce*, an eaſtern weight, of different value in different places, equivalent at Acra in Turkey to 603 pounds, at Tunis and Tripoli to 114 pounds.

CANTAR is alſo an Egyptian weight, which is denominated a *quintal*, and conſiſts of a hundred, or of an hundred and fifty *rotolos*, according to the goods they are to weigh.

**CANTERA**, in *Geography*, a river of Sicily, anciently called "Taurominius," which runs into the ſea; five miles ſouth from Agoſta.

**CANTARE**, *Ital.* to ſing. Singing is a faculty that requires the union of ſo many gifts of *nature*, and ſo much aſſiſtance from *art*, that the complete concurrence and union of both rarely happen. The requiſites from nature are a voice full, flexible and extenſive in compaſs, well-toned, ſweet, clear, and intereſting; with an ear perfectly correct in time and tune. The acquiſitions from art are a good *portamento*, or delivery of the voice from the cheſt, free from naſal or guttural defects, a good ſhake, good taſte and expreſſion, with a rapid, diſtinct, neat, and articulate execution of diviſions, and the power of ſuſtaining a long note with ſteadineſs, and of augmenting and diminiſhing its force by the moſt minute degrees.

The individual in poſſeſſion of all theſe requiſites, will be regarded as a prodigy! and with health, diligence, and good conduct, may be pronounced heir to a great eſtate, ariſing from means the moſt flattering to ſelf-love, and grateful to a good heart: the power of innocently delighting mankind.

Theſe qualifications the critical and faſtidious hearer thinks his due—be it ſo: but in order to balance the account between the performer and his audience, let us remind the latter of the fair and juſt claims which every performer poſſeſſed of great talents has on the public, but in a particular manner, a ſinger, who having arrived at theſe captivating powers by unceaſing ſtudy, toil, and experience, is not only entitled to conſiderable remuneration, but to regard and attention from the public, for its own ſake: for if by neglect, noiſe, and mortification, a vocal performer's mind is diſquieted, and cheſt agitated, that ardent deſire to pleaſe thoſe who ſeem diſpoſed to be pleaſed, and thoſe efforts which encouragement alone can ſtimulate, are chilled and paralyzed, to the great loſs of the feeling part of an audience, and diſgrace of the humbled performer. From ſuch treatment what can be expected but a cold, inanimate, and lifeleſs, performance, without profeſſional zeal, or the enthuſiaſm of genius and talents.

Garrick uſed to ſay, that applauſe was an aliment without which he could not live on the ſtage; and inattention to the part he was repreſenting, he never forgave. He complained to an officer on guard, of a centinel yawning aloud on the ſtage during his acting one of his beſt parts; and he never reſted till Pinto the firſt violin, and leader of the band, had quitted his ſtation, after perceiving him fall aſleep in the orcheſtra, in ſight of the whole houſe, while he was acting one of the moſt impreſſive and afflicting ſcenes in King Lear.

Singing has long been cultivated and cheriſhed in Italy. In the *Cortegiano* of Caſtiglione, written at the beginning of the 15th century, we are told of two ſingers, whoſe merit in a totally different ſtyle of ſinging was ſo equal and ſo great, that they charmed all hearers. Theſe performers are mentioned to prove, that in all the arts there are various roads that lead to perfection, and different means of delighting mankind. *Bidon*, ſays the author of that pleaſing work, has ſuch force, readineſs, and variety of paſſages, that the ſouls of all hearers are ſo excited, inflamed, and raviſhed, that they ſeem tranſported above themſelves, and almoſt exalted into heaven. Nor does *Marchetto Cara* leſs excite the affections by a more tender and touching ſtyle, which commiſerates and ſoothes the afflictions of others, or with ſweet, complaining, heart-felt notes, ſoftens, inſtructs, and penetrates the mind, for ſorrows not their own. Toſi applies to Fauſtina and Cuzzoni, the two great vocal rivals of his time, theſe captivating powers by diſſimilar talents. And we may, perhaps, with equal accuracy and candour affirm, that ſuch are at preſent (1802) the excellencies of the *Billington* and the *Banti*, that whoever prefers the one to the other, only proves that the taſte of hearers is as various as the ſtyle of ſinging of great performers.

Since the eſtabliſhment of operas, no profeſſional talents in any of the fine arts have been more celebrated than thoſe of great Italian ſingers; who being invited to different ſtates and kingdoms, have an opportunity of extending their fame to every part of Europe; and their talents are as well known at Vienna, Madrid, Peterſburgh, Dreſden, Berlin, Munich, and London, as in their own country.

We cannot pretend to render this article a complete elementary treatiſe on ſinging, and, indeed, as Johnſon truly ſaid of books of inſtruction, "nothing is well made by a receipt:" yet, to trace, and ſpecify a few of the firſt principles of the art, may be of ſome uſe to vocal ſtudents out of the reach of better inſtructions.

For thoſe who ſeek vocal precepts in books, we recommend the peruſal of *Toſi* and *Mancini;* and as a ſynopſis of the art, we ſhall preſent our readers with *Tenducci*'s firſt injunctions to his ſcholars. For *ſolfeggj*, or exerciſes for the voice, thoſe of Leo, on which ſo many great ſingers have been formed, are now only uſeful to the performers of old muſic; but new melody requires new *ſolfeggj*, to prepare a ſinger for diviſions and graces of the preſent times. For ſuch, the moſt modern, and perhaps the beſt, are thoſe of Aprile, which, however, are now full 30 years old; but many new melodies have been ſince produced in the vocal compoſitions of Paeſiello, Cimaroſa, Sarti, Haydn, and Mozart, as well as refinements in the performance of Pacchieretti and Marcheſi, with which young ſingers ſhould be made acquainted.

The *Cyclopædia,* being intended to aſſiſt thoſe who ſtudy an art or ſcience without a maſter, we ſhall preſent the ſolitary ſtudent in ſinging with the following inſtructions drawn up in Italian, as we imagined by the late Signor Tenducci, who brought them to the author of the preſent article to reviſe and tranſlate; but on comparing them with the preliminary rules placed at the head of the Engliſh edition of Aprile's *Modern Italian Method of ſinging*, under the title of *Neceſſary Rules for Students and Dilettanti of* VOCAL MUSIC; it appears that the Italian copy of the Inſtructions, brought by Tenducci to be tranſlated, belonged to Aprile, and that the Engliſh tranſlation of theſe rules is literally that with which Tenducci was furniſhed by ourſelves.

*Tenducci's Inſtructions to his ſcholars.*

Neceſſary rules for ſtudents and dilettanti of vocal muſic.

I. The firſt and moſt neceſſary rule in ſinging, is to keep the voice ſteady.

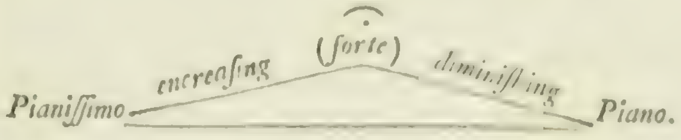
II. To form the voice in as pleaſing a tone, as is in the power of the ſcholar.

III. To be exactly in tune; as without a perfect intonation, it is needleſs to attempt ſinging.

IV. To vocalize correctly; that is, give as open and clear a ſound to the vowels, as the nature of the language, in which the ſtudent ſings, will allow.

V. To articulate perfectly each ſyllable.

VI. To ſing the ſcale, or gammut frequently; allowing to each ſound one *breve*, or two *ſemibreves*, which muſt be ſung in the ſame breath; and this muſt be done, in both, *a meſſa di voce:* that is, by ſwelling the voice, beginning *pianiſſimo*, and increaſing gradually to *forte*, in the firſt part of the time; and ſo diminiſhing gradually to the end of each note, which will be expreſſed in this way,



VII. To exerciſe the voice in *ſolfeggio* every day, with the monoſyllables, *do, re, mi,* &c.

VIII. To copy a little muſic every day, in order to accuſtom the eye to divide the time into all its proportions.

IX. Never to force the voice, in order to extend its compaſs in the *voce di petto*, upwards; but rather to cultivate the *voce di teſta*, in what is called *falſetto,* in order to join it well, and imperceptibly, to the *voce di petto*, for fear of incurring the diſagreeable habit of ſinging in the throat, or through the noſe;—unpardonable faults in a ſinger.

X. In the exerciſe of ſinging, never to diſcover any pain or difficulty, by diſtortion of the mouth, or grimace of any kind; which will be beſt avoided by examining the countenance in a looking-glaſs, during the moſt difficult paſſages.

XI. It is recommended to ſing a little at a time, and often, and if ſtanding, ſo much the better for the cheſt.

XII. That ſcholars ſhould appear at the harpſichord, and to their friends, with a calm and cheerful countenance.

XIII. To reſt or take breath between the paſſages, and in proper time; that is to ſay, to take it only when the periods, or members of the melody, are ended; which periods, or portions of the air, generally terminate on the accented parts of a bar. And this rule is the more neceſſary, as by dwelling too long upon the laſt note of a muſical period, the ſinger loſes the opportunity it affords of taking breath, without breaking the paſſages or even being perceived by the audience.

XIV. That, without the moſt urgent neceſſity, of either a long paſſage, or of an affecting expreſſion, the words muſt never be broken, or divided.

XV. That a good *meſſa di voce*, or ſwell of the voice, muſt always precede the *ad libitum* pauſe 𝄐 and *Cadenza.*

XVI. That in pronouncing the words, care muſt be taken to accord with the ſentiment that was intended by the poet.

XVII. That the acute and ſuper-acute ſounds muſt never be ſo forced as to render them ſimilar to ſhrieks.

XVIII. That in ſinging, the tones of the voice muſt be *united,* except in the caſe of ſtaccato notes.

XIX. That in pronouncing the words, double conſonants in the Italian language, muſt be particularly enforced, and care taken not to make thoſe that are ſingle ſeem double.

XX. To practiſe the *ſhake* with the *greateſt care and attention,* which muſt generally commence with the higheſt of the two notes, and finiſh with the loweſt.

XXI. That the ornaments and embelliſhments of ſongs ſhould be derived from the character of the air, and paſſion of the words.

As Aprile was the real author of theſe precepts, to whom we did not allow an article when we were at work upon the letter A, not knowing whether he was ſinging Alleluiahs in this world or the next, we ſhall endeavour here to make him and our muſical readers ſome amends for the omiſſion.

Theſe rules are ſhort, but clear and uſeful; to ſuch as have neither the advantage of a good maſter, nor are in poſſeſſion of Toſi's *Obſervations on florid Song*, in the original, or the excellent tranſlation by Gaillard, which is now become ſcarce; and, though the book was written early in the laſt century, moſt of the precepts it inculcates are ſtill good, and have not yet been ſuperſeded by thoſe of any better work on the ſubject in our own language. See Tenducci.

APRILE, Giuseppe, in *Biography*, a celebrated Italian opera ſinger, with a *ſoprano* voice, born in 1746. He performed, during 20 years, the principal man's part in moſt of the great theatres of Europe. In 1763 at Stuttgard; in Jomelli's Didone, at Milan; at Florence, ſerious men's part in burlettas by Anſoſſi, as *Il Geloſo in cimento*, &c. and at length he fixed at Naples, where we heard him ourſelves in 1770.

We found his voice ſweet and flexible, but not very powerful, or equal, in its whole ſcale. He had, however, a good ſhake, an elegant perſon, and much taſte and expreſſion.

Since that time, his favour, as well as taſte and ſcience, increaſed by ſtudy and experience. He had a reflecting and contemplative mind, was well acquainted with the *coſtume* of paſt and preſent times, as well as with the ſtyles of compoſition and taſte in ſinging. When he retired from the ſtage, he dipt into compoſition, and compoſed ſome of the moſt graceful and pleaſing *duetti di camera*, which perhaps ever appeared. During many years he was regarded as the beſt ſinging maſter in Europe. He compoſed and publiſhed new *ſolfeggj*, which were very much wanted, as thoſe of Leo, admirable in their day, were become almoſt vulgar and uſeleſs, by the change of ſtyle, both in compoſition and ſinging.

We were very much pleaſed with a remark which this enlightened muſician made to an Engliſh lady, one of his ſcholars, at Naples, concerning a perſon of low birth, and without education, being accidentally introduced into high life, and learning to ſing, with a powerful voice, a good perſon, and every requiſite neceſſary for a comic ſinger, a good mimic, and a great portion of natural humour. But her great ambition was to become, or at leaſt to be thought, a ſerious ſinger in the cantabile and *gran guſto* of Italy. But Aprile obſerved, that "it was impoſſible ſhe ſhould ever ſucceed in the ſerious and pathetic ſtyle, not only for want of a diſpoſition for ſerious things, but a mind accuſtomed to elegance, refinement, and cultivated feelings."

CANTARILLA, in *Geography*, a town of Spain, in the province of Murcia; 3 leagues from Murcia.

CANTARINI, Simon, in *Biography*, ſurnamed the "Pezareſe" from his having been born at Pezaro in 1602, was the diſciple and friend of Guido, and acquired diſtinguiſhed excellence as a painter, by imitating that great artiſt. The works of the ſcholar were often miſtaken for thoſe of the maſter. He died at Verona in 1648.

CANTARO, in *Commerce*, an Egyptian weight, which at Naples is equivalent to 25 pounds, at Genoa to 150 pounds. At Leghorn there are three kinds of cantaras, one weighing 150 pounds, another 151, and a third 160 pounds. The pound of Leghorn is 8 ounces.

Cantaro is alſo a Spaniſh liquid meaſure, in uſe eſpecially at Alicant, containing three gallons.

Cantaro is alſo a meaſure of capacity, uſed at Cochin, containing four rubies, the rubi 32 rotolos.

Cantaro, in *Geography*, a town of Naples, in the province of Principato Citra; 8 miles N. N. E. from Policaſtro.

CANTATA, the title of a ſhort lyric poem, conſiſting of alternate recitation and air. The word *Cantata*, according to Du Cange, was uſed in the church as early as the year 1314, to expreſs what we at preſent mean by *anthem*, with which it is ſtill ſynonymous in Germany; being chiefly confined in the Lutheran church to ſacred muſic. The Romiſh church had many admirable *ſacred cantatas* during the laſt century, by Cariſſimi, Graziani, Baſſani, and others. And during the preſent century, Domenico Scarlatti ſet one at Rome for Chriſtmas Eve, which was performed in the apoſtolic palace, 1717. Bononcini ſet another, 1729, for the ſame occaſion and place. The difference at preſent between *ſacred cantatas* and *motets* ſeems to be the recitative.

The ſecular *cantata* is a ſpecies of compoſition extremely well ſuited to the chamber, in which fewer parts, fewer great effects, and leſs light and ſhade, are neceſſary, than in eccleſiaſtic or dramatic Muſic; for the performance being in ſtill life, and the poet and muſician without an orcheſtra or choir to aſſiſt in painting the ſtronger paſſions, compoſers aimed, for a long time, at no effects out of the power of a ſingle voice and a ſingle inſtrument to produce.

Cantatas of conſiderable length, accompanied by a numerous band, are uſually performed in Italy on great occaſions of feſtivity: as the reconciliation of princes after long diſunion, or the arrival of great perſonages in the capital of a ſtate. Thus, when pope Ganganelli and the king of Portugal were reconciled, in 1770; and ſoon after, when the Emperor Joſeph arrived at Venice, on his firſt viſiting Italy, cantatas were ſung at Rome and Venice equal in length to an opera. But theſe differ eſſentially from what is uſually meant by a cantata or monologue for a ſingle voice, conſiſting of ſhort recitatives, and two or three airs at moſt; as they are occaſional poems in which ſeveral ſingers are employed; but though in dialogue, they are performed, like oratories, without change of ſcene, or action.

As *cantatas* were firſt ſuggeſted by the muſical recitation of the opera in which the chief events were related in recitative; in like manner they received ſeveral progreſſive changes during the 17th century, previous to their perfection. Firſt, they conſiſted, like opera ſcenes, of little more than recitative; with frequent formal cloſes, at which the ſinger, either accompanied by himſelf or another performer on a ſingle inſtrument, was left at liberty to ſhew his taſte and talents.

The next change was in having a ſingle air, generally in triple time, diſtinct from the recitative, and repeated to different ſtanzas after each narrative part of the poem, like modern ballad airs. At this time the term *da capo* not being in uſe, the air was written over again, as often as it was wanted, ſometimes in exactly the ſame notes, but more frequently, with little changes and embelliſhments to the ſame baſe, and to different ſtanzas.

Before the invention of recitative, madrigals for voices alone, and afterwards for inſtruments in uniſon with the ſeveral vocal parts, conſtituted the chief muſic that was performed in the chamber, and in private concerts, till ſolo ſongs, accompanied by a ſingle inſtrument, were brought into favour by Caccini and his imitators, in Italy and other parts of Europe. See Caccini.

Adami tells us, page 194, that Giovanni Domenico Poliaſchi Romano, admitted into the Pope's chapel 1612, compoſed ſeveral cantatas in a good ſtyle, and in the beſt taſte of ſinging, which were printed 1618; and page 195, that the Cavalier Loreti Vittorij da Spoleto, ſoprano in the pope's chapel 1622, and one of the firſt evirati employed in muſical dramas on the ſtage, was a celebrated compoſer of *Arie, e* Cantate *da Camera*.

The firſt time, however, that we have found the term Cantata, uſed for a ſhort narrative lyric poem, was in the *Muſiche varie a voce ſola del* Signor Benedetto Ferrari da Reggio, printed at Venice 1638; which is twenty years more early than the period at which the invention of cantatas is fixed by ſome writers, who have given the honour to Barbara Strozzi, a Venetian lady, who, in 1653, publiſhed vocal compoſitions, under the title of Cantate, *Ariette e Duetti.* Ferrari, *detto della tiorbo*, for his excellent performance on that inſtrument, was one of the earlieſt compoſers of operas for Venice. Of the two firſt muſical dramas that were performed in that city, 1637 and 1638, Ferrari was only the poet; but in 1639, he was author both of the words and muſic of the opera of Armida, as he was of ſeveral ſubſequent muſical dramas.

Cariſſimi, Ceſti, Luigi Roſſi, Stradella Legrenzi, Baſſani, Aleſſandro Scarlatti, Gaſparani, d'Aſtorga, Marcello, Bononcini, Porpora, and Handel, all cultivated cantatas, and added ſomething to the beauty of their conſtruction.

The golden age of *Cantatas*, in Italy, was the beginning of the laſt century, when they were brought to their greateſt degree of perfection, without other accompaniment than a baſe viol, and harpſichord, by the genius and abilities of Aleſ. Scarlatti, Franceſco Gaſparini, Giovanni Bononcini, Antonio Lotti, the Baron d'Aſtorga, and Benedetto Marcello; and, at a later period in a more elaborate ſtyle, with accompaniments, by Nicolo Porpora, and Giovanbattiſta Pergoleſi, who ſeem to have been the laſt eminent compoſers that cultivated this ſpecies of chamber drama, till it was revived by Sarti.

The moſt voluminous and moſt original compoſer of cantatas that has ever exiſted, in any country to which our enquiries have reached, ſeems to have been Aleſſandro Scarlatti. Indeed, this maſter's genius was truly creative; and we find part of his property among the ſtolen goods of all the beſt compoſers of the firſt forty or fifty years of the laſt century.

Pergoleſi's cantatas will be conſidered with his other works, elſewhere.

The French followed the Italian faſhion in their rage for *cantatas*. Their great lyric poet, Baptiſte Rouſſeau, and others, wrote a great number, which were ſet *à la Lulli*, and ſung *à la Françoise*; but having never been heard *out* of France, nor could the muſic now be found, we believe, *in* it, we ſhall be excuſed, it is hoped, if we refrain from diſturbing the aſhes of the dead. There is an excellent critique on *Cantatas*, particularly thoſe of his own countrymen, by M. Ginguené, in the new *Encyclopædie*, in which he has treated the ſubject with much judgment and good taſte.

In England, *cantatas* were publiſhed early in the laſt century, by Handel, Bononcini, Attilio Arioſti, Gaſparini, Roſeingrave, and Dr. Pepuſch; as difficult to find now, perhaps, as thoſe of Clerambaut, Monteclair, Campra, Mouret, and Batiſtin, in France.

But *Cantatas*, which were compoſed with more care, and ſung with more taſte and ſcience than any other ſpecies of vocal muſic, during the latter end of the 17th century and beginning of the laſt, ſeem to have been wholly laid aſide, after the deceaſe of Pergoleſi, till revived by Sarti, who has ſet, in the manner of cantatas, ſeveral of Metaſtaſio's charming little poems, which he calls *canzonette*. Theſe exquiſite compoſitions were produced by Sarti expreſsly for the voices of Pacchierotti, Marcheſi, and Rubinelli, and are, in all reſpects, the moſt perfect and complete models of *chamber muſic* that have ever come to our knowledge.

Indeed, it is to be lamented that a ſpecies of compoſition ſo admirably calculated for concerts as the *cantata*, ſhould now be ſo ſeldom cultivated: as it contains a little drama entire, having a beginning, a middle, and an end, in which the charms of poetry are united with thoſe of muſic, and the mind is amuſed while the ear is gratified. Opera ſcenes, or ſingle ſongs, now ſupply the place of cantatas in all private concerts; but, beſides the loſs which theſe ſuſtain when taken out of their niche, as they were originally calculated for a numerous orcheſtra, they can ſeldom be completely accompanied by a ſmall band.

Cantatilles, *French*, the diminutive of *Cantate*. It ſeems to be equivalent to *Canzonetta* in Italian, when a few lines of recitative precede a ſhort air.

CANTATRICES, in *Middle Age Writers*, hired weepers, and waiters at funerals.

CANTAYA, in *Geography*, a ſmall iſland of the Eaſt Indian Ocean, ſituate in a gulf formed by the weſt point of the iſland of Java.

CANTECROIX, a town of Brabant, in a ſmall territory of the ſame name; 5 miles S.E. from Antwerp.

CANTEEN, in French *Cantine*, is the cabaret, tavern, or place in a garriſon-town or city, where the garriſon or troops have the privilege of purchaſing ſpirits, wine, and beer at a much cheaper rate than they can buy them at other taverns or public houſes. For the moſt part every citadel, fort, fortreſs, and caſtle, has the *droit de cantine*.

Canteen for tobacco, in French *Cantine du Tabac*. By an ordinance of the 30th July, 1720, the king of France eſtabliſhed a ſufficient number of ſuch canteens for furniſhing his troops with the tobacco neceſſary for their conſumption.

Canteen-*maſter*, or *Canteen-keeper*, in French *Cantinier*, is the perſon who has charge of the canteen, diſpoſes of things in it, and makes the proper, neceſſary, and authorized diſtributions in it.

Canteen, a ſmall veſſel uſually made of tinned plate or wood, in which ſoldiers, when on their march, or in the field, carry their liquor. The uſe of wooden canteens has for ſome time been general in the Britiſh armies. They are made cylindrical, like barrels, 7½ inches diameter, and 4 inches long outſide, holding three pints. (See *Manufacture of* Canteens, *Plate* I. *fig.* 1.) Mr. George Smart, a very ingenious mechanic of Ordnance Wharf, Weſtminſter-bridge, who manufactures theſe in great numbers for government, having adopted and contrived a very complete ſet of machines for abridging of labour therein, has liberally permitted us to deſcribe and make drawings of this manufacture, which will, we truſt, be acceptable to our readers. The wood which Mr. Smart uſes, is the beſt wainſcot, or foreign oak, which is ſawed out into boards ¾ of an inch thick; theſe, after being planed, are cut in the direction of the grain, into ſlips 1¾ inches broad, and the whole length of the board, by a circular ſaw called a ripping-ſaw, ſimilar to that in *fig.* 2. except that the groove, G, and ſlider, H I, are omitted; A is the circular, or wheel-ſaw, made of ſteel plate, with fine teeth; on the end of its axis is a pulley, B, turned by a band going round it, and round a large drum under the bench, C C, driven by a horſe-wheel. In *fig.* 3. is ſhewn the manner of fixing the ſaw, A, to its ſpindle, between two pieces of metal, C and D; one of which, C, is part of the ſpindle, and the other, D, is a moveable one, puſhed towards the ſaw by a nut, E, working on a ſcrew, at the end of the ſpindle; the plane of the ſaw in the ripping machine is not fixed exactly at right angles to the bench, CC, but at the proper angle for the ſtaves of the canteen, (which are cut from theſe ſlips,) when put together to form a cylinder of the true ſize. The truth with which theſe ſaws cut, being ſo great, that the edges do not want planing. D, *fig.* 2. is the guide for the edge of the board as it is cut, which, for cutting ſlips of different widths, can be moved nearer to, or farther from the ſaw, by looſening the thumb-nut, E, the ſcrew from which moves in an opening, F, in the bench, CC, and it is always kept parallel to the plane of the ſaw, by two equal levers, L, L. A workman takes one of the boards, and puts its edge againſt the guide, D; when he puſhes it forwards, the ſaw, A, cuts it along into ſlips very quick; theſe ſlips are delivered to another workman, who uſes a ſaw, called a croſs-cutting ſaw, repreſented in *fig.* 2. the guide and ſaw of which have been before deſcribed; G, is a groove cut in the bench to receive a ſlider, H, acroſs one end of which another piece, I, is fixed, having a notch, J, in the underſide for the ſaw to paſs through, when it is ſlid forwards; the end of the ſlip, K, which is to be croſs-cut, is puſhed up cloſe to the guide, D, and the piece, I, and ſlide, H, are puſhed towards the ſaw which cuts it off inſtantly; the ſlide is then drawn back, and the ſlip, K, puſhed up to the guide, D, for another length as before. Theſe pieces, which are 4½ inches long, and 1½ inch broad, are for the ſtaves of the canteen. The ſtaves, *b*, *fig.* 1. and *fig.* 6. which have a hole in them for the cork or bung, are firſt cut out by the ſame means as the common ſtaves, but of twice the thickneſs; the piece, *a b c*, *fig.* 6. of this is cut out at once, by a machine called a tenanting or rebating machine, ſhewn in *fig.* 4. A A is a bench, in the middle of which is fixed a frame, carrying two circular ſaws, ſet at the proper angle to each other, to cut out the piece; D, is an inclined bed, with a grove, G, and ſlider, H and I, (as before deſcribed in *fig.* 2.) at the bottom of this bed, is fixed a piece of thick iron plate, E, acting as a guide to the ſtave while it is cutting: near the middle of this bed is the ſaw, *c*, the plane of which is parallel to the bed, D: a little farther on the bed is the ſaw, *d*, with its axis nearly horizontal; that end of its ſpindle which carries the ſaw, is ſupported by a crooked iron, *e*, faſtened down to the frame by ſcrews, ſo as to be capable of adjuſtment; the pulleys, *f* and *g*, on the ſpindles of the ſaws, are very near to each other, ſo that the ſame band turns them both; it firſt paſſes round a large drum, driven by a horſe-wheel, under the floor, then comes over a pulley, *h*, to change its direction; it next paſſes round the pulley, *g*, and then *f*, turning the two ſaws, (as repreſented ſeparately in *fig.* 5.) it afterwards paſſes over the two pulleys, *k* and *l*, to change its direction to the drum again: the piece of wood which receives the pulley, *l*, can be ſlid in and out of the tube, *m*, and fixed at any place by a pin, to tighten the band as it ſtretches: the piece of wood intended for the ſtave is laid againſt the croſs, I, of the ſlider, H, and held tight while it is puſhed forwards; the ſaw, *c*, cuts the plane, *a b*, *fig.* 6. and as the ſtave advances, the plane, *bc*, is cut by the ſaw, *d*, *fig.* 4. The hole, *d*, in theſe ſtaves, for the corks, are bored by the machine repreſented in *fig.* 7. A, is a ſpindle with a pulley, B, on it, turned by a band, going quite round it, and a drum (with a velocity of 1800 revolutions per minute); at the end, *a*, of this is a male ſcrew to faſten on the common borer, or centre-bit, *fig.* 8.; D and E, *fig.* 7. are two ſmooth wooden rails, for a ſlider *fig.* 9, to move upon, in the middle of which is faſtened a ſmall piece of wood, *a*, having a hole through it at *b*, and a ſhoulder at *d*; the workman takes one of the ſtaves out of the box, G, and, putting one of its ends againſt the ſhoulder, *d*, of the ſlider, *fig.* 9, and one of its edges againſt the bottom board, holds it faſt, while he puſhes it forward againſt the borer. When it is neceſſary to uſe a different ſized borer, the ſlides, D and E, and frame, H H H, which holds them, can be raiſed or lowered, and fixed by two ſcrews, I, J. The common and bung ſtaves thus prepared, are given to a workman who uſes tools repreſented by *figs.* 10, 11, and 12, Canteen. *Plate* II. *fig.* 10. is a thick block of wood, in which is turned a circular groove, *a a*, ½ an inch deep, and ¼ of an inch wide; it is for ſetting the ſtaves up in; when the groove is filled with ſtaves, the workman takes a ſcrew-hoop, *fig.* 11, which is a thin plate of ſteel, with a ſquare lump at one end, and another near the other end, to receive a ſcrew, *c*, to tighten it; the workman puts this tool over the ſtaves, as ſeen in *fig.* 13, and turns the ſcrew, *c*, until the ſtaves are brought cloſe enough, to drive on the iron truſs-hoop, *fig.* 12. Theſe cylinders, or canteens, are taken to a workman, who turns them in a lathe, *fig.* 14, where A is the pulley on the mandrill, turned by a band from a large wheel, worked by a man; B is a conical chuck, on the end of the mandrill, on which a canteen is driven by a mallet; the lathe is then ſet to work, and the ends of the ſtaves or chime turned ſmooth by a tool laid in the notch, *a*, of the reſt, C; another tool like a hook is then uſed, for cutting the groove on the inſide of the ſtaves, for receiving the head. The boards for the heads are firſt ſawn out, as before deſcribed, into ſquares 7¾ inches each ſide, theſe are cut circular by a lathe, *fig.* 15: the mandrill has a wooden chuck on one end, with four ſteel points in it; a workman takes one of the ſquare boards, G, and puts it up againſt the points in the chuck, and to confine it while it is turning, he uſes a piece of wood, D, one end, *d*, of which is placed againſt the middle of the board, and the other has a ſmall hole in it to receive the point of a ſcrew, F, working in the puppet, E; the lathe is then turned, and the board cut to the proper diameter, by a chiſſel laid in the notch in the reſt, C. The next operation is heading and hooping the canteens, which is done by knocking off one of the truſs-hoops, and putting one of the heads into the groove; the ſtaves are then tightened by the ſcrew hoop, *fig.* 11, ſo that the hoop of the canteen may be driven on; the other head is then put in, and the hoop on, in the ſame manner; and the wires, *a*, and another not ſeen, *fig.* 1, are put in; they are for receiving the belt by which the canteen is carried by the ſoldier. They are, laſtly, proved, by pouring a ſmall quantity of hot water into them, and ſtopping the cork-hole with a wooden ſtopper, when they are ſhook, and the hot water rarefying the air within, the ſame will ruſh out violently, and diſcover any ſmall leak that it may have. The ſlips of iron plate for the hoops are cut from large plates of ſheet-iron, by the ſhears, *fig.* 16. A is the centre of a ſtrong wooden lever eight feet long, which has a ſteel blade, *a a*, two feet long, fixed by three ſcrews to the underſide of it; D is a ſtrong bed ſhewn ſeparately in *fig.* 17, on the top of which the other blade, *b b*, is fixed, by three hooks, *c*, *c*, *c*, the upright legs of which go through the bed, and are fixed by three nuts; between the back of the blade and theſe hooks, three wedges, *d*, *d*, *d*, are put in; by drawing which the blade can always be brought near enough to the other blade, *a a*, to cut; C C, are two guides to ſteady the lever, B; near one end of the blade a piece of iron, *e*, is fixed on the lever, B, which acts as a ſtop to the edge of the plate, E, as it is cut; *f* is another ſtop for the ſame purpoſe, which ſlides through a hole in the bed, and is puſhed up by a ſpring, *g*, under the bed. The plate of iron, E, is puſhed forwards from behind by one man, while another is lifting up the lever, B, till it reaches the ſtops, *e*, *f*; the man at the handle then puſhes it down, and cuts the length of a hoop at once off the plate, when the lever is down the underſide of it puſhes down the ſtop, *f*, ſo that the hoop may fall off; when the lever is lifted up to cut another hoop as before. The holes for the rivets of the hoops are next punched by a machine, repreſented in *fig.* 18. A is an iron lever, having a punch fixed in it at B, under this is fixed a dove-tailed groove, C, to hold a piece of ſteel, *d*, which has ſeveral holes of different ſizes in it, to ſuit different punches, any one of which can be brought under the punch, and fixed by the ſcrews, in each ſide of the groove, C: acroſs the top of the groove, an iron plate, *e*, is fixed, with a hole in it, for the punch to go through; its uſe is to prevent the hoop, (which is put under it), after it is punched, from riſing with the punch; D is a ſcrew put into the bench, to prevent the punch from being driven too far into the hole; the boy who works this machine lifts up the lever, A, puts one end of the hoop under the plate, *e*, and then puſhes it down, which makes the hole; he then lifts it up again, and puts the other end under to make the hole in it; firſt hooking the hole before made, over the pin, E, which determines its length.

After the hole is punched, a machine, ſhewn in *fig.* 19, is uſed, to cut the ends of the hoops round; A is the lever, and B the cutter faſtened to it; C is the other fixed cutter, which can be adjuſted by a ſcrew, E, fixed to the bench; F is a guide, between which the lever, A, paſſes, to keep it ſteady; the end of the piece of iron for the hoop, is laid by the boy who attends the machine, upon the fixed cutter, C, and the handle is puſhed down to cut it off. The hoops are then bent round a block, and riveted in the common way. By theſe ingenious contrivances, the operations are rendered ſo ſimple, that a good workman will head and hoop 200 of the canteens in one day, working 14 hours; and two active men will cut with the ſhears, (*fig.* 16,) 60 hoops in a minute: great attention muſt be paid to keeping the truſs-hoops always of the proper ſize, as they are apt to expand with continual uſe, which is the reaſon of their being ſo thick, (*fig.* 12,) and if they are too large, the heads of the canteens will not fit.

CANTEL, *Cantellum*, in *Ancient Engliſh Writers*, denotes a cuſtom of ſelling by the lump, without tale or meaſure. Spelman derives the word from *quantillum*, and defines it by over meaſure, or what is added over and above ſtrict meaſure. Kennet derives it from the old word *cant*, a hundred, that is the ſale of about a hundred weight; anſwering to what we now call the taking of a hundred pound on content; as when we take it in a bag, ſealed up without telling the pieces.

CANTEL, PETER-JOSEPH, in *Biography*, was born in the dioceſe of Rouen, in 1645; and having entered into the ſociety of the Jeſuits, paſſed his days in their college at Paris, where he devoted himſelf to literature, with an ardour which haſtened the termination of his life, in 1684. His principal labours conſiſted in preparing the Delphin editions of the claſſics: and he publiſhed Juſtin and Valerius Maximus, the latter of which he enriched by ſix diſſertations on Roman affairs. He alſo wrote a treatiſe "De Romana Republica," printed at Paris, in 1684, 12mo. and eſteemed an excellent abridgment of Roman antiquities; alſo, "Metropolitanarum Urbium Hiſtoria Civilis et Eccleſiaſtica," tom. i. Paris, 1684, 4to. Nouv. Dict. Hiſtor.

CANTELEU, in *Geography*, a town of France, in the department of the Lower Seine, and diſtrict of Rouen; one league W. from Rouen.

CANTEMIR, DEMETRIUS, in *Biography*, prince of Moldavia, and a deſcendant of a noble Tartarian family, was born in 1673, and educated in part at Conſtantinople, whither he was ſent in his youth as a kind of hoſtage. Diſappointed by the Ottoman Porte in his expectations of ſucceeding his father, as prince of Moldavia, he conceived a prejudice againſt the Porte; and though he continued at Conſtantinople till the year 1710, when the war broke out between the czar Peter the Great of Ruſſia and the Porte, and was appointed by the latter, governor of Moldavia, he preferred the rank of prince of the country. With this view he violated his fidelity, and entered into an agreement of mutual aid and friendſhip with the czar. When the Ruſſian arms failed of ſucceſs, he was obliged to quit the Turkiſh territories, and to follow his new patron, who recompenſed him with the title of prince of the Ruſſian empire, ſovereignty over the Moldavians ſettled in Ruſſia, and other conſiderable appointments. His reſidence was at Charcof in the Ukraine till 1713, when he removed to Moſcow. Here on occaſion of his ſecond marriage with a Ruſſian princeſs in 1719, he ſhaved his beard, and changed his Turkiſh mien for the European. The czar made him a privy-counſellor; and Cantemir accompanied him in his different wars, conducting himſelf ſo as to gain general eſteem. In going to Derbent he was ſhipwrecked, and loſt ſeveral papers which he had taken great care and pains in compoſing. He died at his eſtate in the Ukraine in 1723. Cantemir was ſtudious and learned, and is ſaid to have underſtood 11 languages. He was the author of ſeveral works. His "Hiſtory of the Growth and Decay of the Ottoman Empire," A. D. 1300—1683, written in Latin, and publiſhed in an Engliſh tranſlation by Tindal, Lond. 1734, fol. is charged by Gibbon (Hiſt. vol. xi. p. 434.) with containing ſtrange blunders in oriental hiſtory, though he acknowledges that the author was converſant with the language, annals, and inſtitutions of the Turks. His "Syſtem of the Mahometan Religion," was written and printed in the Ruſſian language, by order of czar Peter; his moral dialogues entitled "The World and the Soul," were printed in Moldavia in Greek and Moldavian; "The preſent State of Moldavia," was printed in Latin; his "Muſical Airs with Turkiſh Words," and "An Introduction to Muſic," in Moldavian. He was alſo the author of other pieces, which were either loſt in his ſhipwreck, or ſtill remain in MS. Moreri. Gen. Biog.]

CANTEMIR, ANTIOCHUS, was the ſon of the preceding, by whom he was carefully educated, and initiated in ſtate-affairs. He was ſucceſſively ambaſſador from the Ruſſian court to thoſe of London and Paris; and, in the different revolutions of his own country, he conducted himſelf with ſingular prudence. His chief diſtinction conſiſted in his having firſt applied the Ruſſian language to the compoſition of poems of any extent or dignity; and he wrote tranſlations of Anacreon and the epiſtles of Horace, beſides various ſatires, odes, fables, &c. His ſatires, like thoſe of Boileau, were a happy mixture of ſtrong ſenſe and poetry, and many of his verſes are become proverbial in the Ruſſian language. He alſo publiſhed tranſlations in proſe of the "Plurality of Worlds," the "Perſian Letters," and "Algarotti's Newtonian Dialogues." He was a member of the academy of Peterſburg, and died in 1744. The abbé Guaſco wrote his life in French, and tranſlated his ſatires into that language. He was much inclined, at an early age, to the ſtudy of the Scriptures, and printed a "Concordance to the Pſalms," in the Ruſſian language. Nouv. Dict. Hiſt.

CANTER, WILLIAM, an eminent linguiſt and philologer, was born at Utrecht of an eminent and reſpectable family in 1542, and ſtudied firſt at Louvain, and then at Paris. Being obliged to leave Paris in 1562, on account of the civil wars, he viſited ſeveral univerſities in Germany and Italy, and at length ſettled at Louvain, where he purſued his literary occupations with an aſſiduity and ardour, which terminated his life at an early age in 1575. Thuanus ſays, that he deſerved to be reckoned among the moſt learned men of his age, and laments his immature death as a great loſs to literature. He underſtood ſix languages, beſides that of his own country, viz. the Latin, Greek, Hebrew, French, Italian, and German. Temperate, and even abſtemious in his diet, he was ſingularly methodical in the diſtribution of his time for ſtudy. He began at ſeven in the morning, and not ſooner, becauſe early riſing did not ſuit his conſtitution, and purſued his literary avocations very intenſely till half paſt eleven. He then walked out an hour before dinner, and another hour after he had dined. Having ſlept an hour upon his couch, he reſumed his ſtudies, and proſecuted them without interruption till midnight, devoting the laſt hours of the day to correſpondence with his friends, and other buſineſs that required a leſs degree of attention and labour. He had collected, during his ſhort life, a very excellent and curious library, conſiſting of the beſt authors in various languages, and a number of Greek MSS., which it was his intention to have publiſhed with Latin verſions and notes, if his life had been prolonged. The damage which his library ſuſtained from an inundation at Louvain in the winter of 1573, was an affliction, which would have proved fatal to him, if his friends had not aſſiſted him in collecting his ſcattered books and MSS., and repairing the injury they had ſuſtained. The principal works of Canter are eight books under the title of "Variæ Lectiones," containing emendations and explanations of ſeveral ancient authors, publiſhed at different times, and reprinted in Gruter's Theſaurus, tom. iii. Latin verſions of the "Caſſandra of Lycophron," of ſome "Pythagorean ethical Fragments from Stobæus," of the "Diſcourſes of Ariſtides," and of "Syneſius," &c. Notes on the "Familiar Epiſtles and Offices of Cicero," various readings on ſeveral MSS. of the "Septuagint," editions of "Euripides," of "Æſchylus," of "Sophocles," and of various other authors; and ſeveral Latin poems in the Deliciæ Poetarum Belgarum. Moreri.

CANTER, in the *Manege*, denotes the ſlow gallop, which is a ſoft and eaſy pace in which moſt people delight. Berenger (Hiſt. and Art of horſemanſhip, vol. i. p. 71.) conjectures, that our word canter, expreſſive of this pace, may owe its derivation to the Latin term "Cantherius," which was the appellation of the horſe, that uſually performed it. Dr. Johnſon, in his Dictionary, calls this pace the Canterbury gallop, and defines it to be the hand gallop of an ambling horſe, called a canter, and probably derived from the maſters riding to Canterbury on eaſy ambling horſes. "How juſt the derivation may be," ſays Berenger, "I will not preſume to decide; but the definition muſt puzzle all who are horſemen, and all who are not." See CANTHERII.

CANTERBURY, in *Geography*, is the capital of the county of Kent, and the metropolitical ſee of the archbiſhop, who is primate of all England. The preſent city occupies a ſite which, during the Roman colonization of Great Britain, was a military ſtation of that warlike people, and, according to the opinion of many eminent antiquaries, was the Durovernum of Antoninus's Itinerary. Three other principal Roman ſtations, which Mr. Somner calls *Castra Riparenſia*, were connected with this, by three different Roman roads, ſome traces of which have been diſcovered. The names of theſe ſtations, and their reſpective diſtances, are thus given by Antoninus. From Durovernum to ad portum Ritupis (Richborough) 12 miles; to ad portum Dubris (Dover) 14 miles; and to ad portum Lemanis (Lime) 16 miles. Without entering into the Roman hiſtory of this place, it may ſuffice to remark, that various relics of that people have occaſionally been found here. Beſides ſome ſeats and walls, which appear to have a Roman foundation; ſome Moſaic pavements, urns, coins, &c. that have been diſcovered, are evident memorials of that people. In the Saxon heptarchy, Canterbury, or, as then called, Cantwarabyrig, was the principal place in the kingdom of Kent, and, during the reign of Ethelbert, was conſtituted the metropolitical ſee of all England. This monarch, having given a favourable reception to St. Auſtin, and his forty monks, who landed in the iſle of Thanet in the year 597, was pleaſed to aſſign for their reſidence that part of the ancient Durovernum which is now called "Stable-gate," and which had formerly been a kind of chapel, or oratory for the royal family, where they had been accuſtomed to worſhip, and ſacriſice to their gods. The miſſionaries entered the town in proceſſion, ſinging a hymn. They were firſt reſtricted to the precincts, and, though zealous in their miniſterial functions, did not make much progreſs in converting proſelytes, till the king aſſumed, and recommended Chriſtianity. This example produced numerous converts; and ſome monkiſh chroniclers do not heſitate to aſſert, that 10,000 perſons of both ſexes were baptized in the river Swale in one day. This is too improbable to be credited in the preſent age. Auguſtin having, however, completely eſtabliſhed himſelf here, dedicated an ancient church to the honour of Chriſt, and Ethelbert founded an abbey, which was afterwards called St. Auguſtin's, the ſite, &c. of which has ſince been occupied by the biſhop's palace. (See AUGUSTIN, vol. iii.)

Canterbury is particularly diſtinguiſhed for its military, as well as eccleſiaſtical fame. Succeſſively occupied by the Romans, Saxons, Normans, &c. it became the ſcene of repeated ſieges and battles in the reſpective wars of each nation. It poſſeſſed a caſtle at the Norman Conqueſt, as it appears from the Domeſday-book that the conqueror obtained it in exchange from the archbiſhop and abbot of St. Auguſtin's. The outer walls, and valla, appear to have incloſed an area of about four acres of land. Nearly the whole of this fortreſs has been deſtroyed, and its foſſes filled up. The walls and gates, which formerly ſurrounded the city, have nearly ſuffered the ſame fate. Some of the latter remain, and parts of the former ſtill retain their original characteriſtics. The whole extent of the wall meaſured nearly one mile and three quarters in circumference. Its thickneſs, on a medium, is about ſix feet, and at certain intervals were formerly twenty-one fortified towers. Without, there was a deep foſs, nearly 150 feet wide, which environed the whole. The different entrances to the city were protected by ſix fortified gates, each of which gives name to the reſpective wards, or parts of the city, wherein they are ſituated. Beſides theſe, there were ſome ſmaller paſſages through the walls, called poſterns. Weſt-gate ſtands on a bridge, which croſſes the river Stour, and is the largeſt of theſe ſtructures. It conſiſts of two lofty ſpacious towers, embattled, portculliſed, and machicolated, and is now uſed as the city priſon. Archbiſhop Sudbury is ſaid to have built this gateway, and the wall which proceeded from it northward on the bank of the river. Further north, is a ſmall poſtern entrance, and near it is a large pile of building, called the Abbots-mill, the machinery of which was conſtructed principally from deſigns, by that great engineer, the late John Smeaton. The Northgate is very peculiar and remarkable, from having a long narrow church over it, which takes its name from the gate. Next to this, eaſtward, was Queningate, in which part of a Roman arch may yet be diſcovered on the outſide of the wall. Near this is a poſtern, which is occaſionally opened for the convenience of the deanery, and ſome of the prebendal houſes. Burgate, and St. George's gate, are in the eaſtern ſide of the wall. The latter is directly oppoſite to Weſtgate, and is conſtructed and fortified in the ſame manner. In each tower of this gateway is a ciſtern, from which pipes iſſued, to convey water to different parts of the city. Beſides theſe, there were nine other gates, which belonged to the cathedral and to the monaſtery. Some of theſe are diſtinguiſhed for their architectural ornaments; particularly that of Chriſt-Church. This, ſays Mr. Somner, is a very goodly, ſtrong, and beautiful ſtructure, and, according to an inſcription on the cornice, was built in the year 1517. The principal front of this building is highly enriched with niches, canopies, ſhields, and other ornaments. The moſt conſiderable building, and greateſt ornament of Canterbury, is the cathedral church, dedicated to Chriſt. This magnificent and ſpacious edifice diſplays the various ſtyles of architecture which characterized different ages from the eleventh to the ſixteenth century. The Danes beſieged this city in 1011, and on the twentieth day of the ſiege ſet it on fire, and completely conſumed the cathedral. Egelnothus, or Agelnoth, the archbiſhop who governed the ſee from 1020 to 1038, refounded, and made conſiderable progreſs in rebuilding this ſtructure, which was again burnt in 1067. The preſent edifice appears to have obtained its foundation from archbiſhop Lanfranc, who was invited from Normandy by the Conqueror, in 1073. He is ſaid to have completed the building, according to the then prevailing Roman ſtyle, in the courſe of ſeven years. In conſequence of accidents by fire, and the dilapidations of time, different ſubſequent archbiſhops made various alterations, additions, and improvements: but to paticularize the whole would exceed our due limits. One or two prominent circumſtances muſt ſuffice for the preſent work. Further, and very detailed particulars may be found in Dart's "Hiſtory of Canterbury Cathedral;" and in Goſling's "Walk in, and about Canterbury." In 1130, the new choir, built by archbiſhop Anſelm, was dedicated with great ſolemnity in the preſence of king Henry I. and his queen, David, king of Scotland, and many of the nobility of both kingdoms. On the 29th of December, 1170, archbiſhop Becket was barbarouſly murdered at the foot of the altar. He was buried here, where a ſumptuous ſhrine was erected to his memory, and the monks having canonized him, his tomb was reſorted to by an innumerable concourſe of pilgrims from all parts of chriſtianized Europe. This circumſtance gave more extenſive celebrity to Canterbury than any other event, and from that period the place continued to increaſe in monaſtic buildings and inhabitants, till Henry VIII. diſſolved the bigotted deluſion and the religious foundations at once. Eraſmus and Stowe have each given a particular deſcription of Becket's ſhrine, from which it appears that beſides a coffin of gold, there were many jewels, &c. employed to decorate the remains of this ſaint. (See Becket, vol. iv. p. 1.) The preſent cathedral conſiſts of a nave, ailes, choir, tranſepts; two towers riſing at the weſt end, one riſing from the centre, ſome private chapels, or oratories, a chapter-houſe, cloiſters, &c. Some of theſe buildings diſplay much ſkill and beauty in their architecture, and ſome are further ornamented by many ancient and curious monuments. Among the latter may be noticed thoſe of Henry IV. and his queen; Edward the black prince; cardinals Chatillon and Pole; archbiſhops Courtney, Chicheley, Bourchier, Walter, Reynolds, Kemp, Stratford, Peckham, Warham, Langton, and Sudbury; beſides many others erected to the memory of eminent and diſtinguiſhed characters. At a ſhort diſtance eaſt of the city walls, are the remains of St. Auguſtin's monaſtery, which was certainly the firſt Chriſtian eſtabliſhment in Great Britain. This was firſt built in 978, and though at firſt only a ſmall foundation, ſoon increaſed in extent and revenues. Patronized by a king, and under the government of a man like Auguſtin, it attracted the company and property of numerous devotees from all parts of the converted iſland; and in proportion as Chriſtianity was extended, ſo was the ſacred fame of this place propagated. At the diſſolution, Henry VIII. ſeized the town, and intended to make it a palace for himſelf. It was afterwards granted to cardinal Pole; and in 1573, queen Elizabeth kept her court here in her progreſs through Kent. The boundary wall incloſed about ſixteen acres of land. Some of the remaining buildings are appropriated to a brewery, and its fine entrance gate-way, though ſtill a beautiful object, is gradually crumbling away.

Canterbury formerly contained ſeventeen churches and pariſhes within the walls, and three in the ſuburbs; but of theſe only fifteen remain. The Jews, Preſbyterians, Quakers, Methodiſts, and Baptiſts, have each their reſpective houſes of worſhip. Among theſe buildings we may particularize the following, as having ſomething beautiful or curious to entitle them to the notice of the inquiſitive traveller. St. Martin's church, being compoſed partly of Roman brick, is conſidered the moſt ancient building in the city. St. Dunſtan's church is a large, handſome ſtructure. St. Margaret's church contains an eccleſiaſtical court, where the archbiſhop, archdeacon, &c. hold their ſeveral viſitations; and where various cauſes relating to eccleſiaſtical affairs are tried. This city is provided with many other public edifices; and its hoſpitals and other charitable eſtabliſhments are numerous. Here are two public libraries, a priſon for Eaſt Kent, a free grammar ſchool, a theatre, aſſembly rooms, and a large guild-hall, which, beſides containing ſeveral convenient apartments, is embelliſhed with ſome portraits of perſons who were benefactors to the city. The city workhouſe was eſtabliſhed by act of parliament in 1728. The name of Chaucer, and his Canterbury tales, with the Chequer inn, which was at one time occupied by our veteran poet and his fellow-pilgrims, will long be aſſociated in the memory of all lovers of old Engliſh poetry.

The corporation of the city conſiſts of a mayor, recorder, twelve aldermen, a chamberlain, town-clerk, twenty four common council men, and ſome inferior officers. It ſends two members to the imperial parliament, who are elected by the freemen, of whom there are reſident, and non-reſident, upwards of 1600. An act of parliament for paving, lighting, and watching the city was obtained in 1787, ſince which time the appearance of Canterbury has been materially improved, and its local advantages greatly augmented. The road-way of all the principal ſtreets is paved with Guernſey pebbles, and the foot-paths with Yorkſhire ſquared ſtones.

Canterbury is ſeated in a fine valley on the banks of the river Stour, which, dividing itſelf into different channels, thus forms five or ſix iſlands, ſome of which are built on, and are united to other parts of the city by bridges. At the ſouthern ſide of the walls is an artificial conical eminence, called Dane John Hill, or Dunge-Hill. This mount and its vicinity having been judiciouſly planted, and laid out in pleaſant walks, is thereby rendered a very attractive and delightful promenade to the citizens. The principal manufactories of the city are for worſted, ſilk, and cotton, and here is a manufactory for blending ſilk and cotton, or ſilk and worſted, which is known by the name of Canterbury muſlins, or ſtuffs. In the environs of the city are numerous hop plantations. See Kent.

Canterbury being a county in itſelf, its magiſtrates have authority to determine all diſputes at law between the citizens, and to try capital offences. On theſe occaſions the mayor ſits as judge, attended by the recorder, and the bench of aldermen. This city is 55 miles eaſt from London, and has markets on Wedneſdays and Saturdays, beſides ſeveral fairs. The houſes in 1800 amounted to 1799, and the inhabitants to 9000. Goſling's "Walk in and about the City of Canterbury," 12mo. 4th edition. Haſted's "Hiſtory of Kent," 10 vols. 8vo. "Kentiſh Travellers Companion," 12mo. 4th edition. King's "Obſervations on ancient Caſtles," Archælogiæ, vol. iv. p. 392, &c. Dart's "Hiſtory of Canterbury Cathedral," fol.

Canterbury, a townſhip of America, in Rockingham county, New Hampſhire, ſituated on the eaſtern bank of Merrimack river, 14 miles N. by W. from Concord, 45 N.W. from Exeter, and 54 from Portſmouth. It contains 1038 inhabitants.—Alſo, a townſhip in Windham county, Connecticut, on the weſt ſide of Quinnabang river, which ſeparates it from Plainfield; 7 miles E. by S. from Windham, and about 10 or 12 N. from Norwich.

Canterbury *Bells*, in *Botany*. See Campanula Trachelium and Glomerata.

CANTERII, or Cantherii, in *Ancient Architecture*, rafters or joiſts of a houſe, which reach down from the ridge to the eaves.

CANTH, in *Geography*, a town of Sileſia, in the principality of Breſlau, on the Wiſtritz; 12 miles S.W. of Breſlau.

CANTHARÆ, among the *Ancients*, a kind of candleſtick. See Branch.

CANTHARELLUS, in *Botany*, (Juſſ. 4. Merulius, With.) See Agaricus and Merulius.

Cantharellus, in *Entomology*, a ſpecies of Staphylinus, of a black colour, with the wing-caſes glaucous, and yellowiſh at the tip. Inhabits Sweden. *Gmelin.*

CANTHARIAS *lapis*, in *Natural Hiſtory*, a name given by ſome writers to a foſſile ſubſtance ſuppoſed to reſemble a beetle. We ſometimes meet with parts of the ichthyperia or bony parts of fiſhes, which are ridged longitudinally, much in the manner of the outer wing of ſome of the beetle tribe; and from their ſize and ſhape, which is an oblong, or oval one of the bigneſs of a common beetle, and ſometimes of the largeſt, and at others of the very ſmalleſt kinds; theſe have been called by ſome, petrified beetles and *cantharia lapides*; others have extended the name to ſuch ſpecies of amber as have in them the body or any fragment of the beetle of any ſpecies.

CANTHARIDES, in the *Materia Medica*, are beautiful green flies with a golden burniſh, found in the ſouth of France, in Spain and Italy, of very important uſe in the Materia Medica. (For the natural hiſtory of this fly, ſee Meloe *Veſicatorius*). The cantharides of Italy are the largeſt, but the Spaniſh are accounted the beſt, and are the moſt uſed, whence the inſect is alſo commonly known by the name of *Spaniſh Fly*.

When theſe flies appear in ſwarms, they are accompanied by a very diſtinguiſhable and fetid ſmell like that of mice, and this effluvium is ſo powerful, when proceeding from a large ſwarm, that perſons expoſed to it, experience ſymptoms of ſtrangury, and ardor urinæ, pain in the eyes, and violent itching over the body.

The common way of collecting theſe inſects is, to ſpread cloths under the trees containing them, to ſhake them down, and then kill them by putting them on a hair ſieve and expoſing them to the vapour of boiling vinegar, or elſe (which is the commoneſt mode) ſimply to immerſe them in vinegar and water. They are then dried thoroughly, either in the ſun or in airy chambers, being frequently turned by the hands armed with gloves. They are then well and carefully packed in cloſe wooden barrels lined on the inſide with paper. The inſect, when well dried, is ſo light as to weigh no more, on an average, than about a grain and a half.

Cantharides in this ſtate will keep well for a conſiderable time, and if in cloſe veſſels, they hardly acquire any ſmell, but in open veſſels and in the damp, they putrify in ſome degree. They are liable, however, notwithſtanding their very corroſive quality, to be attacked by very ſmall worms, which gradually crumble them to powder in every part except the wings. The acrid quality, however, is not very materially injured thereby, and remains for a great length of time, though ſlowly diminiſhing in intenſity.

The ſingularly acrid property of cantharides has led ſeveral chemiſts to endeavour by chemical analyſis, to determine in what principle it reſided. Thouvenell's experiments on this ſubject are of ſome importance. This chemiſt found four diſtinct ſubſtances in cantharides, ſome of which are doubtleſs ſtill further decompoſable. After ſoftening them with warm water, he ſubmitted them to ſtrong preſſure, which left behind about half the weight of a parenchymatous matter that was not further attended to. Hot water then extracted about $\frac{3}{8}$ of the whole weight of a yellowiſh red and very bitter ſubſtance, which gave an acid by diſtillation, and melted out a quantity of yellow oil which floated at top. This latter concretes by cooling, and has a very acrid taſte and the peculiar ſmell of the inſect. Heated with ether, it ſeparates into two diſtinct concreſcible oily matters, that are ſoluble in ether, being green, waxy, and peculiarly acrid, and the other untouched by this menſtruum, remaining yellow. The green oil is about $\frac{1}{10}$ of the whole, and the yellow oil after this has been ſeparated, amounts to about a fifth. All the active medicinal properties have been ſuppoſed to reſide in theſe oils, and eſpecially the green. The truth of this ſuppoſition is ſomewhat queſtionable to the full extent, ſince this oil is inſoluble in water, which liquid certainly extracts ſome acrid properties from the inſect, but it is yet highly probable, that it is the moſt active portion. This concrete oil being very difficult of putrefaction and more of the nature of reſin, will alſo explain why the virtue of the inſect remains ſo active after very long keeping. The whole of the active power of the inſect, both that which reſides in the oil and in the extract, is readily diſſolved by alcohol diluted with as much water; and in this way the tincture of cantharides is prepared. Something further, however, may probably be done on this ſubject by an able chemiſt who ſhould purſue this reſearch.

Cantharides have a peculiar and ſomewhat nauſeous ſmell. When taken into the mouth, no taſte is at firſt perceived, but after a while, a ſenſation of burning comes on which is very durable. Taken into the ſtomach even in the doſe of two or three grains, it produces moſt excruciating pain and ſenſation of burning, inflaming and excoriating the whole inteſtinal canal, and producing death with great agony. It alſo has a peculiar tendency to affect the urinary organs, occaſioning very acute pain and burning on paſſing the water, often attended with blood, and alſo with ſtrangury, or a painful difficulty of paſſing it. Theſe affections of the bladder often are felt in a ſlighter degree after the external uſe of this inſect.

The chief uſe to which cantharides are applied is, in Bliſters, as has already been fully deſcribed under that article, and need not here be repeated. No other known ſubſtance anſwers the effect ſo certainly, ſo extenſively, and on the whole, ſo eaſily to the patient, and hence this inſect is one of the moſt valuable articles of the materia medica. Much refinement has been attempted in the compoſition of the different bliſtering plaſters, and many additions have been propoſed, but with very dubious advantage. It does not appear that any ſubſtance can *add* to the veſicating power of the fly when freſh and good, and when a *diminiſhed effect* is wanted, the ſimpleſt and ſureſt way is, either to leſſen the quantity of the cantharides or the uſual time of its application.

The internal uſe of cantharides is juſtified by found experience, but on account of its extreme and dangerous activity, it ſhould be employed with great caution. The urinary affection is generally the firſt and moſt unqueſtionable ſign of an exceſſive doſe. It is given internally ſometimes in dropſy, but chiefly in debility of the urinary and generative organs. Camphor is ſaid to check the diſpoſition to ſtrangury, but this is extremely doubtful. Opium is more certainly an uſeful addition. The doſe of the fly in ſubſtance is about half a grain, and can ſeldom be borne oftener than once, or at moſt, twice a day. The tincture of cantharides is alſo uſed internally in doſes of from ten to twenty drops. Beſides the above-mentioned uſes of this medicine, the tincture has often been found of ſingular ſervice joined with decoction of elm-bark or ſarſaparilla, in obſtinate cutaneous diſeaſes. The tincture is uſed externally as a ſtimulating application.

CANTHARIFERA, in *Botany*, (Rumph. Amb.) See Nepenthes Destillatoria.

CANTHARINUS, in *Entomology*, a ſpecies of Cerambyx, (Saperda Fabr.) that inhabits Germany. The colour is ferruginous: thorax cylindrical, with the antennæ and legs black. Fabr. Linn. &c.

Cantharinus, in *Entomology*, a ſpecies of Cimex. The colour of this inſect is black: thorax armed with a ſingle tooth, and marked with a white circle: wing-caſes cinereous, with four yellow ſpots: ſcutel yellow. A native of Denmark. Mull. Zool. Dan.

CANTHARIS, in *Entomology*, a genus of Coleopterous inſects diſtinguiſhed by having the antennæ filiform: thorax in general margined, and ſhorter than the head: wing-caſes flexile: ſides of the abdomen edged with folded papillæ. Linn. &c.

The ſpecies of this genus Gmelin divides into three ſections, the firſt containing thoſe which have four hatchet-ſhaped feelers; the ſecond, thoſe with filiform feelers, the laſt joint of which is ſetaceous, (or true Malachius of Fabricius); and the Lymexyla, or thoſe having the anterior feelers projecting, the laſt joint but one, with a large ovate cleft appendage, and the laſt joint ovate and acute. The ſpecies are theſe:

*Section* 1, virideſcens, fuſca, marginella, media, haematoſtoma, punctata, dichroa, multicolor, livens, diſtincta, exuſta, livida, rufa, obſcura, limbata, lateralis, ſmaragdula, biguttata, minima, cardiacæ, albicans, teſtacea, atra, marginata, bimaculata, pallipes, pallida, ruficollis, flavipes, melanocephala, bipunctata, angulata, nigra, pulicaria, caneſcens, coccinea, bicolor, bilineata, trilineata, altica, oculata, collaris, cuprea, argentea, janthina, americana, rufipes, berolienſis, fulva, ſerrata, tropica, ſonchi, caſpica, flaveola, violacea, vireſcens, lepturoides, nigripes, melanura, hiſtrio, picea, chalybea, tricolor:

*Section* 2, æuea, bipuſtulata, hæmorrhoidalis, viridis, ſanguinolenta, cyanea, pedicularia, nemoralis, faſciata, equeſtris, ochropus, chryſomeloides, cæruleocephala, ſuecica, Herbſtii, erythromelas:

*Section* 3, abbreviata, proboſcidea, barbata, navalis, ſaxonica, morio; which ſee reſpectively.

Obſ. The Fabrician genus *Cantharis*, includes only thoſe Linnæan ſpecies of the genus that have four hatched-ſhaped feelers: jaws bifid; lip entire; and antennæ filiform.

CANTHARIUM, in *Ancient Geography*, the moſt weſtern promontory of the iſle of Samos.

CANTHARUS of a *Fountain*, among Roman writers, denotes the part, or apparatus, out of which the water iſſued.

It was made in divers forms, ſometimes in that of a ſhell, at other times in that of an animal, which yielded water at its mouth, eyes, and the like.

Cantharus, in *Eccleſiaſtical Writers*, denotes a fountain, or ciſtern, in the middle of the atrium, before the ancient churches, wherein perſons waſhed their hands and faces before they entered.

Cantharus, in *Ichthyology*, a ſpecies of Sparus. The tail is immaculate, and the body lineated longitudinally with yellow. Linn. Arted. &c. Inhabits the Mediterranean.

CANTHELEA, or Canthalia, in *Ancient Geography*, a maritime town of Africa, in the territory of Curubis, and in the vicinity of Carthage. This town is ſaid to have received its appellation from the Pagan deity Saturn; ſince, according to Sanchoniatho and Damaſcius, the word *el* in the Phœnician tongue had a particular relation to that deity. In confirmation of this opinion it is added, that there was a town in that place called "Vicus Saturni," the ſtreet or town of Saturn, where Jerome is ſaid to have lodged during his exile in Curubis.

CANTHERII, in *Antiquity*, a general name applied by the Romans to horſes uſed on many different occaſions, but which was always underſtood to mean "geldings." Many unſatisfactory conjectures have been formed concerning the etymology of this word. The beſt explanation, ſays Berenger (Hiſt. &c. of Horſemanſhip, p. 71,) ſeems to be that which deduces it from the Greek, κανθελιος, canthelion, which, by no unuſual change of one letter for another, may be made "cantherion;" ſignifying, in its original ſenſe, a pack-ſaddle; and as it was uſual to caſtrate the "cantherii," or pack-horſes, in order to make them gentle and quiet, it became a cuſtom to call all caſtrated horſes, "cantherii," though appointed to other ſervices beſide that of carrying packs or burdens. In proceſs of time, people, who, for various reaſons, rode on horſeback, began to prefer theſe cantherii, or geldings, for their calmneſs of temper, to other horſes.

CANTHI Colpus, or Irinus, in *Ancient Geography*, a gulf of India, according to Ptolemy, into the northern part of which the river Indus diſcharged itſelf.

CANTHI Statio, a port of the Indian ſea, to the weſt of the moſt weſtern mouth of the river Indus.

CANTHIUM, in *Botany*, a genus formed by La Marck and adopted by Juſſieu, for two plants nearly allied to Gardenia and Coffea; but ſtated by La Marck to differ from the former in their two-ſeeded berries, and from the latter, in their ſhort flowers and ſimple ſtigma. One of them is Gardenia ſpinoſa of the younger Linnæus, G. Dumetorum of Willdenow, which ſee; for the other, ſee Webera *Tetrandra*. As La Marck has not inſerted this genus in his Illuſtrations, he appears to have ſince formed a different judgment concerning it: but as the detail of ſpecies in that work is not yet completed, it cannot be determined in what manner he would now diſpoſe of theſe two plants. We have followed the arrangement of Willdenow.

CANTHUS, in *Anatomy*, the junction of the ſuperior and inferior eyelids. Hence there is an internal and an external canthus. Theſe parts are alſo called the angles of the eye; that which is towards the noſe being termed the inner or greater angle; and that which is towards the temple, the outer or leſſer angle of the eye.

Canthus, in *Chemiſtry*, the lip of a veſſel; or that part of the mouth of a veſſel, which is a little hollowed, or depreſſed, for the eaſy pouring off a liquor.

Hence, to pour by decantation, is to pour through that place.

Canthus, in *Entomology*, a ſpecies of Papilio (*Dan. Feſt.*)

*Feſt.*) that inhabits North America, the wings of which are entire, and fuſcous above: anterior pair immaculate: on the upper ſurface of the poſterior ones ſix ocellar ſpots. *Fabr.* &c. Obſ. This inſect is noticed by Linnæus (*Amoen. Acad.*) under the name of Papilio Eurydice, and it is alſo Papilio Argante of Cramer.

CANTI, *Carnaſcialeſchi.* Songs ſung through the ſtreets of Florence in the Carnival, by perſons in maſks, during the time of Lorenzo il Magnifico. Theſe ſongs, after the manner of the Greek *ſcolia,* were applicable to perſons of different trades and occupations; among the reſt there is one for thoſe who played on the rebec, the trumpet, and various inſtruments of muſic uſed in the German troops, called by the Italians, *Lanzi.* The firſt of theſe ſongs that were performed in this manner, were ſet by Arrigo Tedeſco, Maeſtro di Cappella of the church of St. John, and a muſician of great eminence, of whoſe compoſitions various ſpecimens are preſerved by Glarianus. Ant. Franceſco Grazzini, commonly called, *Il Laſca,* collected and publiſhed the words of theſe ſongs in 2 vols. 8vo., under the title of *Tutti i trionſi, Carri, Maſcherate o* Canti Carnaſcialeſchi *andati per Firenze* dal tempo del magnifico Lorenzo de' Medici ſino al anno. 1559. The poetry of theſe ſongs is ſtill in great favour with the Florentines.

CANTICLE, a hymn or pious ſong: as, *the Song of Songs,* by Solomon. The firſt and moſt ancient canticles were compoſed on occaſion of great and memorable events, and ſhould be ranked among the moſt ancient hiſtorical monuments. Canticles were ſung in Chorus, and often accompanied with dances, as appears in the ſacred writings, where the moſt conſiderable compoſition of this kind is the *ſong of ſongs,* which ſome authors imagine to be an epithalamium, compoſed by Solomon on his own nuptials with the daughter of the King of Egypt. But theologians find under this allegory, the union of Chriſt and the church. M. Cahuſac ſaw nothing in the *ſong of ſongs,* but a regular opera: the ſcenes, recitatives, duets, choruſſes, every thing neceſſary to an opera, according to him, is contained in this *canticle,* and he doubts not but that it has been repreſented. *Rouſſeau.*

CANTICLES, or *the Song of Songs,* in *Biblical Hiſtory,* a Hebrew mode of expreſſion to denote a ſong ſuperlatively excellent in ſtile and ſentiment. Of this ancient poem the author is aſſerted, by the unanimous voice of antiquity, to have been Solomon; and this tradition is corroborated by many internal marks of authenticity. In the very firſt verſe it is ſaid to belong to Solomon: he is the ſubject of the piece, and the principal actor in the conduct of it. Alluſion is made to the rich furniture of his palace, chap. i. 5.; to the horſes and chariots which he purchaſed of Pharaoh king of Egypt, i. 9. 1 Kings x. 28, 29.; to Amminadab, who was eminent for ſuch chariots, and who married one of Solomon's daughters, vi. 12. 1 Kings iv. 11.; to his building of the temple, under the figure of a palanquin or couch for his bride, iii. 9, 10.; to the materials of which it was formed brought from Lebanon and other hills, iv. 8. In a word, all the leading circumſtances of Solomon's life in a religious view appear to be alluded to, or implied in this ancient poem, and therefore render it probable that it was a production of ſome writer in his age, if not his own compoſition.

That the Song of Songs, from the moſt early period, was deemed a ſacred book, and ranked with the Hagiographa of the Jews, and thence received among the canonical books of the Old Teſtament, may be inferred from the following conſiderations. A tranſlation of it is aſcribed to the ſeventy Jews, who flouriſhed about 300 years before Chriſt, and which ſtill forms a part of the Alexandrian verſion. With the ſame conviction of the ſacred character of the work, it was rendered into Greek, in the ſecond century, by Aquila, Symmachus, and Theodotion. Origen, on the authority of the Jews, contemporary with him, and whom he was in the habit of conſulting reſpecting the authority and literal import of their ſacred books, inſerted it in his *Hexapla,* and wrote ſome homilies upon it, explaining its myſtical ſenſe, which have in part been tranſlated into Latin by Jerome. That the ancient Jews, without exception, conſidered it as a production divinely inſpired, appears moreover from the allegorical ſignification annexed to it by the Chaldee paraphraſe. Joſephus, in his anſwer to Apion, lib. i. 38, gives a catalogue of the Jewiſh books, and includes in the third claſs of ſuch as related to moral inſtruction the Song of Songs. See Bible and Canon. Euſebius, alſo, following his footſteps, makes it the fifteenth of that number. See his Eccleſ. Hiſt. lib. vi. cap. 25. From the Jewiſh ſynagogue the book of Canticles was received into the Chriſtian church, without any doubt of its divine authority. This appears from Origen and Euſebius. It is cited by Ignatius, about the beginning of the ſecond century, as a book of authority in the church at Antioch. It is included in the canon of the apoſtles. See Canon. And in the apoſtolical conſtitutions, a paſſage from the Canticles is quoted. Con. vi. 13. 18. See Constitutions, *apoſtolical.*

Though the Song of Songs comes down to us recommended by the voice of antiquity, its divine authority has been called in queſtion by many writers in modern days. Whiſton thinks it a diſſolute love ſong, compoſed by Solomon when advanced in years, and degenerate in practice; and that therefore it ought to be excluded from the canon of the ſacred books. Taken indeed in its primary and literal ſenſe, it muſt be conſidered as deſcribing a royal marriage, and may therefore be denominated an *epithalamium* or *hymeneal ſong.* The celebrated Michaelis ſuppoſed that the object of it *was to teach God's approbation of marriage.* But the ideas of Harmer appear much more rational, who, though unwilling to give it the name of *epithalamium,* thinks it a marriage ſong to be explained by compoſitions of a ſimilar nature in eaſtern countries. "What can be more likely," ſays he, "to lead us into the literal ſenſe of an ancient nuptial poem than the comparing it with ſimilar modern productions of the Eaſt, along with antique Jewiſh compoſitions of the ſame kind?" Boſſuet, biſhop of Meaux, was of opinion that this ſong was to be explained by the conſideration, that the Jews were wont to celebrate their nuptials for ſeven days together, diſtinguiſhed from each other by different ſolemnities: and this notion has been adopted by the author of "A new Tranſlation of Solomon's Songs, with a Commentary and Annotations." The principal objection to this opinion is, that the conduct of the poem does not admit of ſuch a diſtribution; and the diſtinguiſhing each day by ſome diſtinct ceremony is a mere ſuppoſition unſupported by fact.

The elegant and learned biſhop Lowth devotes two of his *Prælectiones* to an examination of this poem, and he determines it, with Boſſuet, to be a *ſacred drama,* though deficient in ſome of the eſſential requiſites of dramatic compoſition. Sir W. Jones, from his knowledge of Eaſtern poetry, was led to compare ſome parts of it with ſimilar productions among the Arabians, and delivers it as his opinion, that it is to be claſſed with the Hebrew idyls. Poeſ. Aſiat. Com. p. 92. Supported by the high authority of this illuſtrious ſcholar, Mr. M. Good, in an elegant metrical verſion with which he has favoured the public, conſiders the Song of

Songs as forming not one continued and individual poem, but a ſeries of poems, each diſtinct and independent of the other; and he denominates them *ſacred idyls.* "The Song of Songs," he ſays, "cannot be one connected epithalamium, ſince the tranſitions are too abrupt for the wildeſt flights of the Oriental muſe, and evidently imply a variety of openings and tranſitions; while, as a regular drama, it is deficient in every requiſite that could give it ſuch a claſſification." In oppoſition to this it may be remarked, that the ſubject of the poem, from beginning to end, is the ſame; the perſonages, introduced as ſpeakers, are the ſame; and, though to a modern reader the tranſitions in many places may ſeem abrupt, and the thoughts unconnected, the conduct of the piece is not ſuſpended, but carried on under a fable regularly conſtructed, and terminating in a concluſion intereſting and unexpected. The apparent want of connection in the ſentiments of an ancient dramatic compoſition muſt be manifeſt; and it is the buſineſs of a critic to remove thoſe cauſes, by pointing out the place of repreſentation; by aſſigning to the proper characters their reſpective ſpeeches; by unfolding in the hiſtory of the times, the event on which the fable is conſtructed; by marking the commencement and cloſe of the ſeveral acts or ſtages of the action: in a word, by conveying his own imagination, and that of his reader, to the place of exhibition, and thus calling the eye, as it were, to the aſſiſtance of the ear in developing the unity of the ſubject, and ſupplying the ſmoothneſs of the tranſitions.

Having thus produced the ſentiments of others reſpecting the nature and object of the Canticles, we ſhall next briefly ſtate thoſe of an ingenious friend, who conſiders it, for the reaſons which he has adduced, as a parable in the form of a drama.

Firſt, When cloſely examined, it will appear to poſſeſs all the eſſential qualities of a *drama.* The marriage of Solomon with the daughter of Pharaoh, (as related 1 Kings i. 1.) a political event which, from the perſonages concerned in it, would be intereſting to the Jewiſh nation, was, as ſuch, proper to furniſh the fable of it. The writer is entirely left behind the curtain, and the whole of the compoſition is brought forward before the reader in parts between the ſpeakers. The *dramatis perſonæ* are Solomon, the bride, her attendants, and the virgins of Jeruſalem. It ſhould be obſerved, though the fact has indeed been overlooked by the critics, that all advance is made by the lady herſelf. She comes to his palace *unfetched*, and apparently *unſolicited.* Finding him not there, ſhe goes in ſearch of him, intreats to be received into his embrace; and when, without denying, he eludes her intreaties, ſhe purſues him in the ardour of her affection almoſt beyond the bounds of female delicacy and modeſty. On the contrary, the royal ſpouſe is cold at heart, and diſtant, prone to recede, and to intrigue with his favourite concubines, but anxious to conceal his indifference and infidelity under laboured encomiums on the beauty of his ſpouſe. The action is complete, poſſeſſing a beginning, a middle, and an end, and compoſed of ſcenes, the ſhifting of which, if obſerved by a modern reader as by an ancient ſpectator, would have preſerved the conduct of the piece uniform and conſiſtent. The plot, it muſt be allowed, is very ſimple, the intricacies of it ariſing only from thoſe unforeſeen impediments which were thrown by rival beauties in the way of the royal bride, and which threatened to deprive her of the object of her attachment. The cataſtrophe is the triumph of honourable love over the allurements of ſeduction, and the ſecurity of virtuous enjoyment over the torments of jealouſy and illicit fruition.

Secondly, Conſidered as a *parable*, like other parables, while it conveys a literal ſenſe intereſting and appropriate, it conveys likewiſe a religious leſſon of ſupreme importance. Now the method of decyphering a fable or parable is, not by ſeeking under the veil of the allegory certain maxims of recondite wiſdom, which bear no reſemblance to the literal ſenſe, but by facts generally known and fully underſtood: nor is the interpretation to be deemed *true*, unleſs, as in the caſe of the parable of Nathan or that of the ſower, there ſubſiſts an obvious and characteriſtic analogy between the ſimple and the metaphorical acceptation. On this principle, it is apprehended that, in the parable of the Canticles, the bride means the *Jewiſh religion*, and the royal ſpouſe the *Jewiſh nation*, repreſented under the name and perſon of their ruler and chief; and the object of it is to delineate, under images borrowed from the connubial ſtate, the conduct of the Iſraelites at large, and that of Solomon in particular, in reſpect to their knowledge and worſhip of Jehovah. In proof of this poſition, it will be neceſſary to ſpecify a few leading particulars.

1. The relation ſubſiſting between Jehovah and the Jews, as his choſen people, is uſually deſcribed, in the Jewiſh writings, in language expreſſive of the relation between a huſband and the woman who is the object of his peculiar affection and choice. See Iſa. liv. 5. Jer. iii. 1. Ezek. xvi. xxiii. Hoſ. i. Mat. ix. 15. xxv. Rev. xix. 7.

2. The deſcription, given in the poem, of the royal bride conſiſts of thoſe figures and alluſions which, in other parts of the Jewiſh ſcriptures, are employed to delineate the character of *true religion.* Thus ſhe is ſaid to be a *fountain*, to be a *garden*, to have a *vineyard*, to be *more delicious than wine.* See Iſa. v. 1. Mark xii. 1. Iſa. xii. 2, 3. John iv. 14. vii. 37. Pſ. xix. 10.

3. While the royal lover is laviſh of his encomiums on the beauty of his bride, he was cold and faithleſs, and all advance is made by herſelf. This delineates with exactneſs the character of the Jews, with reſpect to their religion. It was beſtowed upon them unaſked and undeſerved. While loud in praiſe of their worſhip, they were ever prone to the idolatry of their neighbours; and the God they were forſaking ceaſed not, as it were, to purſue them, and to ſolicit their return to him. We read of Solomon, (1 Kings i. 1—7.) that the ſtrange women he married were the means of ſeducing his heart from God; and the bride ſeems to have been ſenſible that the virgins, with whom he aſſociated, were the cauſe of alienating his affections from her, and ſhe repeatedly intreats them *not to ſtir up nor awake her beloved.*

4. Solomon built a temple in which the knowledge and worſhip of the true God might be cultivated; and the ſervice of the temple was appointed by the wiſdom of heaven to be but an introduction to the more rational ſervice of the Chriſtian church. For this reaſon, the temple might be conſidered as the *cradle* or *couch* in which the Jewiſh religion was to be nurſed, and, as it were, to be conveyed home to her parent's houſe; that houſe of which God was the owner and author, and of which Chriſt was the chief corner-ſtone. Accordingly the royal lover is repreſented as making a couch for the bride. In this grand palanquin ſhe is conveyed home with her huſband; and here ſhe expects to enjoy his undivided attachment, without any apprehenſion from the ſeductive arts of her rivals. And it is certain that thoſe of the Jews who paſſed over from the temple to the Chriſtian church never afterwards relapſed to idolatry, but ever remained faithful to the worſhip of the true God.

5. The temple being made of the wood of Lebanon, the bridal couch is, for this reaſon, repreſented as made of the ſame timber. Hence with much propriety the royal lover invokes his bride to come from Lebanon, and other hills,

whence the materials for the temple were brought; and hence too, with equal propriety, the language in which the huſband celebrates the accompliſhments of his ſpouſe is copied from that temple which was devoted to her ſervice.

6. When they arrived in the parent's houſe, ſhe informs her huſband, "We have a ſiſter who is little, and hath no boſom." Which means that, when the Jewiſh temple was exchanged for the church of Chriſt, Judaiſm itſelf pointed out the goſpel diſpenſation, which being in its infancy encumbered with rites and ceremonies, had not yet all its vigour and purity. To the information of the bride reſpecting her younger ſiſter the king replies, "If ſhe be a *wall*, we will build for her a palace of ſilver; and if ſhe be a *door*, we will encloſe her with boards of cedar." Which is to this effect: "If the new religion, the younger ſiſter, be intended as a wall or an additional *ſecurity* of the old; if the religion of the goſpel prove an auxiliary to the ſervice of the temple, we Jews will erect for her portion a ſplendid reſidence; we will adopt her as a beautiful appendage of Judaiſm: but if, on the other hand, ſhe will aboliſh the Levitical code, and throw open a *door* to receive the Gentiles to the privileges of the Jews, we will reject her, and endeavour to cloſe up the *breach* which ſhe has made in our diſpenſation." The anſwer of the bride is remarkable: "*I am a wall*;" by which ſhe delicately hints that *ſhe* was the means of encloſing the choſen people of God, and of ſeparating them from the idolatry of their neighbours; but that her younger ſiſter was intended to remove this wall of ſeparation, and to unite the Gentiles with the Jews in the knowledge and worſhip of the true God."

7. The gradual expanſion of revelation, from the firſt dawn of it in the garden of Eden till it reached its meridian effulgence, in conſequence of the death and reſurrection of Chriſt, is thus beautifully pourtrayed in the character of the bride: "Who is ſhe that looketh forth as the *morning*, fair as the *moon*, bright as the *ſun*, and ſerene as the *ſtarry hoſts*?"

Finally, The royal huſband addreſſes his bride as being at the ſame time his ſiſter, *My ſiſter, my ſpouſe*. Theſe two inconſiſtent relations are now eaſily explained. The father of the huſband, the Creator of the Jews, was alſo the author of their religion. The bridegroom and the bride, being deſcended from the ſame great Parent, were alſo a brother and ſiſter.

The metaphorical ſenſe thus capable of being put upon every part of this poem, juſtifies the high appellation of *The Song of Songs*, which has ever been given it. It accounts alſo for its being regarded, by Jews and Chriſtians, as a *ſacred compoſition*, and for its reception firſt into the Jewiſh, and then into the Chriſtian canon. On its firſt publication its allegorical import muſt have been generally underſtood; and it was natural that, as with the proceſs of time it became unintelligible, it ſhould ſtill retain the high rank and eſtimation which at firſt it ſo juſtly acquired. It was alſo equally natural in the firſt Chriſtian writers, on receiving it into the canon of the Jewiſh ſcriptures, but without knowing the true ſignification of it, to interpret it as referring to Chriſt and his church. The interpretation, however, though adopted by moſt modern divines, has only involved it in myſtery, fancy, and abſurdity; and the conſequence was that its claims to inſpiration have been called in queſtion; nor is there any means of reſtoring it, in the eſtimation of rational critics, to the ſacred writings, but by diſcloſing the beautiful leſſon of religious wiſdom concealed under the veil of its allegory. The epilogue, reſpecting the younger brother and ſiſter, demonſtrates that its views terminate in the temple ſervice. While, at the ſame time, the alluſion at the cloſe to the riſe of the goſpel, and the converſion of the Gentiles, which took place ſo many hundred years after Solomon, proves that the author was actuated by divine inſpiration.

CANTICUM, Latin, in *Muſic*, a motet, anthem, or ſacred ſong.

CANTII, in *Ancient Geography*, a people of Albion, or Britain, who inhabited that part of the country which from them was called *Cantium*. See CANTIUM.

CANTILENA, in *Muſic*, an Italian word equivalent to melody, the treble, the principal part of a compoſition, oppoſed to the repieno, or under parts, either in inſtrumental or vocal muſic.

CANTILLANA, in *Geography*, a town of Spain, in the country of Seville, ſeated on the Guadalquiver; 11 miles N.W. of Carmona.

CANTIMARONS, or CATIMARONS, a kind of floats or rafts, uſed by the inhabitants of the coaſt of Coromandel to go a fiſhing in, and to trade along the coaſt. They are made of three or four ſmall canoes, or trunks of trees dug hollow, and tied together with cacao ropes, with a triangular ſail in the middle, made of matts. The perſons who manage them are almoſt half in the water, there being only a place in the middle a little raiſed to hold their merchandiſe; which laſt particular is only to be underſtood of the trading cantimarons, and not of thoſe who go fiſhing.

CANTING-ARMS, among *Heralds*, are thoſe arms which expreſs their owner's ſurname. Theſe anſwer to what the French call *armes parlantes*; they are a ſort of rebuſes, and are never preſumed to be noble. See ARMS.

CANTING-*quoins*, in *Ship Building*, the ſame as *cantic-quoins*. See CANT and QUOIN.

CANTIŒBIS, in *Ancient Geography*, a town of Germany, placed by Ptolemy near the Danube.

CANTIUM, as it is called by Cæſar and Ptolemy, CANTIA of Bede, now *Kent*, derives its name and that of its inhabitants, moſt probably, from the Britiſh word "Cant," which ſignifies an angle or corner, and applied to this part of Britain from its form and ſituation. It is ſeparated from the continent by a narrow ſea, called by Solinus "Fretum Gallicum," but by Tacitus and Ammianus Marcellinus "Fretum Oceani," and "Oceanus Fretalis." The places of Cantium mentioned by the ancients are Durovernum, Durobrivis, Durolenum, Portus Rutupiæ, Portus Dubris, Regulbium or Regulium, and Portus Lemanus, now Canterbury, Rocheſter, Lenham, Richborough, Dover, Reculver, and Leine. Ptolemy reckons Londinum, London, among the cities of the Cantii; but in this particular he was certainly miſtaken. This was probably the firſt diſtrict of Britain which received a colony from the continent; and it is no leſs probable that it had frequently changed its maſters, by new colonies, who came over from time to time, and drove the inhabitants farther north. Amidſt all its revolutions it retains its appropriate name, and it was transferred to all the ſucceſſive tribes by which it was inhabited. At the time of the Roman invaſion its inhabitants were evidently of Belgic origin, who had arrived at ſo late a period, that they differed in no reſpect from their countrymen on the continent. "The inhabitants of Kent (ſays Cæſar, Bell. Gall. l. v. c. 10.) are the moſt civiliſed of all the Britons, and differ but very little in their manners from the Gauls." This reſemblance was owing to the proximity of their ſituation, which, being neareſt to the continent, was moſt frequented by emigrants from thence. It was this ſituation, alſo, that expoſed them to the firſt aſſaults of the Romans. Cæſar, in both his expeditions into this iſland, landed in Kent; and therefore we may conclude, that the Cantii were principally concerned in the vigorous oppoſition that was made to his landing, and in the ſeveral ſkirmiſhes and battles that were fought againſt him after his landing; particularly, they made a very bold but unſucceſsful attempt upon his naval camp. Their reſiſtance, however, was leſs vigorous on the next invaſion of the Romans, in the reign of Claudius; for we learn from Dio (l. lx.) that Aulus Plautius, the Roman general in that expedition, traverſed their country without ſeeing an enemy; and as they now ſubmitted to the power of Rome without a ſtruggle, ſo they continued in a ſtate of quiet ſubmiſſion to it to the very laſt. Cantium, in the moſt perfect ſtate of the Roman government, formed a part of the province which was called "Flavia Cæſarienſis." Henry's Hiſt. vol. i. p. 253, 8vo.

CANTO denotes a part or diviſion of a poem, anſwering to what is otherwiſe called a book. The word is Italian, and properly ſignifies ſong. Taſſo, Arioſto, and ſeveral other Italians, have divided their longer or heroic poems into cantos. In imitation of them Scarron has alſo divided his Gigantomachia, and Boileau his Lutrin, into *chants* or ſongs. The like uſage has been adopted by ſome Engliſh writers, as Butler, who has divided his Hudibras, and Dr. Garth his Diſpenſary, into cantos. A tranſlator of part of Virgil's Æneid, has even ſubdivided a book of Virgil into ſeveral cantos.

Canto, *Ital.* a ſong, part of a poem. *Il canto*, in *Muſic*, implies the firſt treble of a vocal compoſition, in four parts. In a chorus of more than four parts, there is frequently a ſecond canto; as *canto* 2do. the ſecond treble. *Canto fermo*, plain chant, *canto Gregoriano*, the Gregorian chant, or the chant inſtituted by pope Gregory, written in the Roman miſſals, in ſquare black notes, on three or four lines only. *Canto figurato*, florid counterpoint.

CANTOCRA, in *Geography*, a town of Piedmont, 22 miles N.N.W. of Turin.

CANTON, John, in *Biography*, an ingenious natural philoſopher, was born at Stroud in Glouceſterſhire, July 31, 1718, O. S.; and having, at an early age, made a conſiderable proficiency in mathematics, under the tuition of a ſchoolmaſter in his native town, he was taken from ſchool to learn the buſineſs of his father, which was that of a weaver of broad cloth. This employment, ſo unſuitable to his faculties and views, did not reſtrain his ardour in the proſecution of ſcience; and his acquaintance with aſtronomy was at this time ſo conſiderable, that by the help of the Caroline tables he computed eclipſes of the moon and other celeſtial phenomena. He alſo conſtructed ſeveral kinds of dials. In his favourite purſuits he encountered many difficulties and diſcouragements; but devoting thoſe hours to ſtudy, which the family ſpent in ſleep, and reduced to the neceſſity of ſecreting a candle for this purpoſe, he made ſuch progreſs that he was able to conſtruct, with a common knife, an upright ſun-dial of ſtone, which ſerved to ſhew not only the hour of the day, but the riſing of the ſun, his place in the ecliptic, and ſome other particulars. This dial was placed in the front of his father's houſe, and as it excited the admiration of ſeveral neighbouring gentlemen, it was the means of introducing him to their acquaintance, and of gaining for him an acceſs to their libraries. In one of theſe libraries he found Martin's Philoſophical Grammar, in the peruſal of which he firſt acquired his taſte for natural philoſophy. In another library he met with a pair of globes, the uſe of which facilitated his ſolution of various problems. At this time he had the happineſs to be introduced to the acquaintance and patronage of the Rev. Dr. Henry Miles, a diſſenting miniſter at Tooting, near London, well ſkilled in natural knowledge, and a reſpectable member of the Royal Society. Mr. Canton accompanied Dr. Miles to London, in 1737, and after reſiding with him for ſome time, he articled himſelf for five years as an aſſiſtant to Mr. Samuel Watkins, maſter of an academy in Spital-ſquare. Having recommended himſelf in this ſubordinate ſituation, by his ingenuity, application, and good conduct, he was taken into partnerſhip by Mr. Watkins in 1742, and afterwards ſucceeded him in his ſchool, where he remained till his death. The ſcience of electricity had for ſome time engaged the attention of Mr. Canton; and after the diſcovery of the Leyden phial towards the cloſe of the year 1745, he made it the object of his particular inveſtigation, and in the following year his method of determining the quantity of electricity accumulated in it was communicated by Dr. William Watſon to the Royal Society. His mode of doing this, as Dr. Prieſtley obſerves, in his "Hiſtory of Electricity," had a near affinity to the diſcovery of Dr. Franklin. Towards the cloſe of the year 1749, he aſſiſted his friend Benjamin Robins, Eſq. in his experiments for aſcertaining the height to which rockets aſcend, and the diſtance at which their light may be ſeen. In January, 1750, Mr. Canton communicated to the Royal Society his "Method of making *artificial magnets*, without the uſe of, and yet far ſuperior to any *natural* ones." The diſcovery of this method had been made ſome time before; but Mr. Canton, from motives of delicacy, with reſpect to Dr. Gowin Knight, delayed the publication of it, till he was urged to it by Martin Folkes, Eſq. This communication was ſoon followed in the ſame year by his being elected a member of the Society, and by his receiving its gold medal. In this year he was alſo complimented with the degree of Maſter of Arts, by the Univerſity of Aberdeen; and, in 1751, he was choſen one of the council of the Society. On occaſion of the change of the ſtyle in 1752, he gave to the earl of Macclesfield ſeveral memorial canons for finding leap-year, the dominical letter, the epact, &c. which were afterwards publiſhed by Dr. Jennings in his "Introduction to the Uſe of the Globes."

In 1752, Mr. Canton had the honour of being the firſt perſon in England, who, by drawing the electric fire from the clouds, during a thunder-ſtorm, verified Dr. Franklin's hypotheſis of the ſimilarity of lightning and electricity. In 1753 his paper, entitled "Electrical Experiments, with an Attempt to account for their ſeveral Phenomena," was read at the Royal Society. This paper, as well as another communicated to the Society in 1754, contains ſome curious facts and diſcoveries, of which an account will be given in the *Hiſtory of* Electricity. Mr. Canton, in 1752, ſent to the editor of the Lady's Diary a ſolution of the prize queſtion for that year, explaining the phenomenon of the "ſhooting of ſtars." The anſwer was anonymous; but Mr. Thomas Simpſon, who then conducted the Diary, ſent the prize to Mr. Canton, accompanied with a note informing him that, though he had concealed his name, he knew him to be the author, becauſe no one elſe could have anſwered the queſtion. Our author's next communication to the public was a letter in the Gentleman's Magazine for September, 1759, on the electrical properties of the tourmalin; which ſee. In the ſame year the Royal Society received a paper, entitled, "An Attempt to account for the regular diurnal Variation of the horizontal Magnetic Needle, and alſo for its irregular Variation at the Time of an Aurora Borealis." Mr. Canton's obſervations on the tranſit of Venus were communicated to the Royal Society in November 1761; and in 1762, a letter addreſſed by him to Dr. Franklin was read, containing remarks on Mr. Delaval's electrical experiments; in December of the ſame year his curious paper entitled "Experiments to prove that Water is not incompreſſible" was alſo communicated to the Society. See Compreſsion. Theſe experiments, as they refuted the famous Florentine experiment, were carefully examined, and the concluſion deduced from them very cautiouſly received. They were repeated before a committee of the Society, who profeſſed themſelves ſatisfied with their accuracy and with the fact inferred from them; and in conſequence of their report, the council unanimouſly voted to Mr. Canton the gold medal, which was delivered to him on the 30th of November, 1765. In 1768 our author communicated to the Society, "An eaſy Method of making a phoſphorus, that will imbibe and emit Light, like the Bolognian ſtone, with Experiments and Obſervations." See PHOSPHORUS. Mr. Canton was one of the committee of the Royal Society, who, in 1769, took into conſideration the beſt and the moſt effectual method of fixing electrical conductors to preſerve the cathedral of St. Paul's from damage by lightning: and the mode which they recommended has been put into execution. Our author's laſt paper, addreſſed to the Royal Society, was read in December 1769, and contained "Eperiments to prove that the Luminouſneſs of the Sea ariſes from the Putrefaction of its animal Subſtances." Beſides the papers above recited, and which have been ſelected on account of their peculiar importance and utility, Mr. Canton wrote a number of others, which appeared in ſeveral different publications. The compiler of this article had the honour of intimate acquaintance with Mr. Canton for ſeveral of the laſt years of his life; and he can bear teſtimony from his own obſervation to the peculiar neatneſs and elegance of his apparatus, and to the accuracy and addreſs with which he conducted his experiments. He can alſo teſtify with gratitude and pleaſure to the urbanity of his manners, and to the readineſs with which he communicated information to all who wiſhed to receive, and who ſeemed diſpoſed to derive any advantage from it. His death, of a dropſy in the thorax, probably occaſioned by his ſedentary and ſtudious habits, at comparatively the early age of 54, in March 1772, was much regretted by all who knew him, not only as it deprived them of an eſteemed friend, but as his deceaſe was no inconſiderable loſs to the intereſts of ſcience, which he aſſiduouſly cultivated and improved. His wife, whom he married in 1744, and by whom he had ſeveral children, ſurvived him. His eldeſt ſon, Mr. William Canton, ſucceeded him in the academy. Biog. Brit.

CANTON, in *Geography*, a quarter of a city, conſidered as ſeparated and detached from the reſt.

The word ſeems formed from the Italian *cantone*, a *ſquare ſtone*, or *corner ſtone*.

CANTON is alſo more frequently uſed for a ſmall country, or diſtrict, under its ſeparate government. Such are the thirteen Swiſs *cantons*; each of which forms a republic apart; but all are leagued together, and conſtitute what is called the Helvetic body. See SWISSERLAND.

CANTON, in the late organization of the French conſtitution, denotes a ſubdiviſion of a diſtrict, as the diſtricts are ſubdiviſions of the departments. See DEPARTMENT. Each canton is compoſed of a certain number of communes (ſee COMMUNE); and is comprehended within the juriſdiction of a juſtice of peace. The "aſſembly of canton" is compoſed of all the citizens domiciliated within the canton, and who are inſcribed upon the communal liſt of the diſtrict. The firſt conſul nominates the preſident of this aſſembly, whoſe functions laſt five years; and he is aſſiſted by four ſcrutineers and a ſecretary. Each aſſembly of canton divides itſelf into ſections, for the purpoſe of performing the functions that belong to it; and it propoſes two citizens, from whom the firſt conſul chuſes the juſtice of the peace of the canton, and alſo two citizens for every vacant place of deputy. The juſtices of peace, and their deputies are appointed for ten years. In the cities conſiſting of 5000 perſons the aſſembly of canton preſents two citizens for each place in the municipal council; and in cities, where are ſeveral aſſemblies of canton, each aſſembly is empowered in like manner to preſent two citizens for the ſame purpoſe. The members of the municipal councils are taken by each aſſembly of canton from a liſt of 500 perſons of the firſt conſideration of the canton; and theſe councils ſhall be renewed, one half, every ten years. The firſt conſul chuſes the mayors and aſſiſtants in the ſaid councils, who are continued five years in office, but may be rechoſen. The aſſembly of canton nominates for the electoral college of diſtrict the number of members aſſigned to it, in proportion to the number of citizens of which it is compoſed; and it nominates to the electoral college of department, from a given liſt, the number of members aſſigned to it. The government convenes the aſſemblies of canton, and fixes the time of their duration, and the object of their meeting.

CANTON, or QUANG-CHOO-FOO, a city and maritime port of China, and capital of the province of Quang-tong or Canton. The city and the ſuburbs are ſituated for the moſt part on the eaſtern bank of the Pe-kiang river, which communicates by canals with the neighbouring provinces. The city is compoſed, as it were, of three different cities, ſeparated by lofty walls, but ſo connected, that the ſame gate ſerves to paſs from the one and to enter into the other. Theſe three cities united form a regular ſquare, and the city wall is ſaid to be about ſix or ſeven miles in circumference; though the incloſure is occupied partly by pleaſure-grounds and fiſh-ponds, as well as by private and public buildings. The ſuburbs are much more extenſive. The ſtreets are long and ſtraight, chiefly paved with flat ſtones, and ornamented at certain intervals with triumphal arches; ſome of them are covered, and theſe contain the richeſt ſhops. The houſes are generally low, conſiſting only of one ſtory, without windows to the ſtreet; but other buildings, inhabited by the moſt reſpectable merchants and mandarins, are lofty, ſpacious, and convenient. Some of theſe are fitted up in the Engliſh manner, with glaſs windows and fire-grates, the latter of which are found to be uſeful about the winter ſolſtice. A large garden with ponds and parterres ſurrounds the buildings. On one ſide of them is a temple; and on the other, a high edifice, the top of which commands a view of the river and ſhipping, as well as of the city and the country to a conſiderable diſtance. Perſons of condition are carried in chairs; and few females are ſeen in the ſtreets. Theſe, however, are continually crowded, eſpecially with perſons, who are all loaded, and moſt of whom have their heads, legs, and feet bare. There is no other convenience in this city for removing goods from one place to another but by means of porters. The quay on which the European factories are built, and which is very extenſive, is ſituated, without the walls of the city, on the left bank of the river, and diſplays by flags the colours of every nation. Theſe factories compoſe a long range of buildings, of one ſtory, with ſeveral yards. From behind, they form a ſtreet, crowded with ſhops, which are furniſhed with every kind of merchandize; and the ſtreet is cloſed at the two extremities by barriers, beyond which the Europeans are not to paſs. Formerly they went every where, except into the Tartar town, which is contiguous to the Chineſe town. The number of ſtrangers to be ſeen in the ſuburbs, while their ſhips are loading and unloading in the river, together with their various languages, dreſſes, and characteriſtic deportment, would give occaſion to doubt, if a judgment were to be formed from that part of the town, to what nation it belonged. The town of boats is a league above Canton. They are all in ſtrait rows, and form ſtreets. Each boat, being tolerably large and covered, affords an habitation to a whole family; who have alſo a ſmall boat to procure proviſions,

ſions, as well as to go on ſhore when occaſion requires. The number of inhabitants in the town and ſuburbs of Canton is eſtimated at a million and a half; and if we conſider the great extent of the city, the vaſt reſort of trading veſſels and boats, and the immenſe number of mechanics, tradeſmen, merchants, merchants' clerks, porters, watermen, fiſhermen, huſbandmen, and mariners, this eſtimate will not be thought extravagant. The garriſon is ſometimes compoſed of 20,000, at other times of 25,000, and even of 30,000 Tartars. The number of perſons, who are obliged to live on the water in boats, and who are prohibited by the expreſs regulation of the law from ſettling on ſhore, may amount to 300,000, including the women of the town, who are eſtimated at 40,000. Canton is not only one of the beſt and moſt conſiderable ports of China, but it is the only one which Europeans are permitted to frequent; it is alſo the rendezvous of a great proportion of Chineſe veſſels, trading to Cochinchina, Formoſa, Haynan, Siam, Malacca, Achem, Batavia, the Moluccas, Japan, &c. The great objects of import and export are principally carried on in this city by means of agents belonging to companies in Europe. Such have been, as ſir G. Staunton obſerves, (Embaſſy to China, vol. ii. p. 527.) the probity, punctuality, and credit of the Engliſh Eaſt India company in particular, and of their agents, in the eſtimation of the Chineſe merchants, that their goods are always taken, as to quantity and quality, for what they are declared in the invoice; and the bales with their mark paſs in trade, without examination, throughout the empire. Theſe agents are divided generally into ſuper-cargoes and writers; and they are allowed a commiſſion on the buſineſs which they do, according to their ſtations in the ſervice. The exports of Canton conſiſt of many articles, but that which is much the moſt conſiderable is tea; of which the Europeans and Americans received, in 1795, 5,577,200 lbs., and the Engliſh private trade amounted to 23,733,810 lbs. The exports from Canton to India amounted, in 1792, to 330,000l., leaving a vaſt balance in favour of India, which is paid in caſh. The articles purchaſed for India conſiſt chiefly of raw and wrought ſilk, ſugar and ſugar-candy, tutenag, alum, porcelain, camphor, nankeen cloth, quickſilver, and turmeric. In 1792, there were imported into Canton from England, in 16 company's ſhips, to the amount of near 1,000,000l. in lead, tin, woollens, together with furs, and other articles of private trade. The order for woollens only in the following year was 250,000l. higher than the preceding year. The legal trade from the Britiſh dependencies in India to Canton, in 1792, amounted to very near the ſum of 700,000l., beſide opium, which is clandeſtinely imported there, to the amount of about 250,000l. The articles legally imported conſiſted of cotton, tin, pepper, ſandal-wood, elephants' teeth, and bees' wax. The total imports from foreign European nations to Canton, in 1792, amounted to 200,000l.; and their exports to upwards of 600,000l. Many of the imports were of Britiſh manufacture. The Canton artiſts are uncommonly expert in the imitation of European works. They repair, and even make watches, copy paintings, and colour drawings, with great ſucceſs. They ſupply ſtrangers with coarſe ſilk ſtockings, knit or woven at Canton, though few or none of them are worn by the natives. The toys made at Canton, and known under the name of balancers and tumblers, are partly filled, and their equilibrium ſuſtained, by quickſilver. The lapidaries of Canton, who cut diamonds, uſe for that purpoſe adamantine ſpar. The amalgama of tin and quickſilver is applied, by the artiſts in Canton, in making ſmall mirrors, with glaſs blown upon the ſpot from broken pieces of that material imported whole from Europe. The ſpectacles uſed by the Chineſe are formed of cryſtal, which the Canton artiſts cut into laminæ, with a kind of ſteel ſaw, formed by twiſting two or more fine iron wires together, and tying them like a bow-ſtring to the extremities of a ſmall flexible bamboo. The ſiliceous powder of the cryſtal, procured by ſawing, is received into a trough of water; and with that mixture the wire and groove formed in the cryſtal are often moiſtened. The powder of the cryſtal, like that of the diamond, helps to cut and poliſh itſelf. Gold leaf is uſed by the ſilk or velvet weavers in their tiſſues and embroideries. Trinkets alſo are made of it at Canton, which, though not worn by the Chineſe, are ſold in Europe as eaſtern ornaments. Silver is alſo drawn into threads, like gold, to be uſed in the ſilk and cotton manufactures. For the method uſed at Canton in preparing their white copper or petung, &c.; ſee that article.

By the accurate obſervations of Mr. Raper, during the year 1774, cited by Kirwan in his "Eſtimate," &c. p. 97, the temperature of Canton was 75° 14'.; the ſtandard temperature 75° 4'.; the greateſt heat in January 66° 5'., the leaſt 51°; the greateſt heat in Auguſt 89°, and the leaſt 80°. N. lat. 23° 7' 50". E. long. 113° 2' 15".

Canton, a province of China, of which the above deſcribed city is the capital. See Quang-tong.

Canton, a townſhip of America, in Norfolk county, Maſſachuſetts, incorporated in 1797; being formerly the northern part of Stoughton.

Canton, in *Heraldry*, is one of the nine honourable ordinaries; being a ſquare portion of the eſcutcheon parted from the reſt.

It has not any fixed proportion; though regularly it ſhould be leſs than a quarter, it is often only a ninth part, and uſed as an addition, or difference, frequently to expreſs baſtardy. The canton is ſometimes placed at the right corner, and ſometimes at the left; in which latter caſe, it is called a *canton ſiniſter*. For its form, ſee *Plate, Heraldry*.

Canton is alſo uſed for the ſpaces left between the branches of a croſs or ſaltier.

*To* Canton, or diſpoſe of in cantonments, in French *cantonner*, in the *Military Art*, is to diſtribute troops in towns and villages as contiguous to one another and as nearly in the ſame line as poſſible, and in ſuch a manner as to command the avenues to the ſame, and to front the diſtrict of country the enemy is in, or the towns, villages, poſts, or poſitions, he may occupy or poſſeſs himſelf of. Troops are ſometimes cantoned after the fatigues of a ſiege, that has been undertaken early in the ſpring, that they may have ſome time to repoſe and recruit themſelves; ſometimes in the midſt of a fatiguing campaign, for the purpoſe of reſt and refreſhment; ſometimes towards the cloſe of a campaign, when forage is ſcanty and the weather intemperate, till ſuch time as the enemy ſhall go into winter quarters; and ſometimes before the opening of an early campaign for the ſake both of ſubſiſtence and of convenience to a proper or eligible camp of exerciſe, which is at all times within reach of their cantonments, and can be protected from them.

The cantoning of troops is alſo a phraſe occaſionally, though not very properly, made uſe of for the diſpoſing or diſtributing of troops into winter quarters. See the article Quarters.

In a garriſoned town or place, when there is not a ſufficiency of barracks and caſemats for the troops, different diſtricts of it are allotted to different regiments for the accommodation of their officers and men. And ſuch an allotment or diviſion of the town, is ſometimes called the cantoning of it.

CANTONE, in *Commerce*, a meaſure of three gallons, wine-meaſure, at Alicant.

CANTONED, a word uſed in *Architecture*, when the corner of a building is adorned with a pilaſter, an angular column, ruſtic quoins, or any thing that projects beyond the naked of the wall.

Cantoned, Cantone', or Cantonized, in *Heraldry*, is when the four cantons, or ſpaces round a croſs, or ſaltier, are filled up with any pieces.—He bears gules, a croſs argent, cantoned with four ſcallop ſhells.

The word is alſo uſed when there are little pieces in the cantons, or ſpaces, of any principal figure of an eſcutcheon. Thus the ſaltier of Lenox is cantoned with four roſes.

CANTONING, in *Middle Age Writers*, denotes the dividing a thing into hundreds, or ſelling it by hundred weights, or hundreds in tale.

CANTONMENTS, in *Military Art*, are a ſort of tranſient or temporary quarters for different purpoſes, but chiefly for the repoſe of troops. Cantonments differ from quarters in this reſpect, that the former are ſeldom made uſe of but for a ſhort reſt or refreſhment to an army that is much fatigued, but continues to do the ſame ſort of duty in them as in the field; whereas in the latter, duty is performed as in garriſoned places.

In quarters of cantonment, the troops ought to be arranged and diſpoſed of nearly in the ſame manner as in order of battle; viz. with the cavalry on the wings and the infantry in the centre. The cantonments ſhould not be very much ſcattered or extended. They ought not to exceed ten or twelve leagues in front, or be more than four or five in depth. Before you take the field, they ſhould be a little contracted, and then divided or diſpoſed of under the command of five or ſix of the oldeſt generals. One of theſe ſhould command the cavalry of the right wing, another that of the left, and the reſt the infantry in the centre. By ſuch a diviſion or diſpoſition, all orders from the commander in chief will be the more expeditiouſly executed, and the troops will with greater eaſe form their columns when they are going to take the field.

CANTOR, in *Entomology*, a ſpecies of Cerambyx, found in China. The thorax is unarmed, cinereous, with black dots: wing-caſes pale, teſtaceous; bidentated at the tip, and cinereous with black ſpots. *Fabricius*.—Obſ. This is of the middle ſize, and villoſe.

Cantor, *Lat.* a ſinger, a chanter. In the Lutheran church, the *cantor* is the coryphæus of the pſalmody. In moſt parts of Germany, where the proteſtant religion is eſtabliſhed, each pariſh has a cantor to teach ſinging, and to direct the chorus.

Though cantor is a general appellation for a ſinger, it is in a particular manner applied, in this country, to the perſon who has the direction of ſinging the pſalms and hymns in pariſh churches. He is precentor, or leader of the pſalm, which he likewiſe ends, by ſinging the laſt word of every line; ſo that he may be called the alpha and omega of ſacred ſong.

The cantor, who is likewiſe frequently ſchoolmaſter, beſides having a good voice, ſhould neceſſarily underſtand counterpoint; if not in a high degree, at leaſt ſufficiently to correct ſuch errors as may have crept into compoſitions, through the ignorance or careleſſneſs of tranſcribers. He ſhould likewiſe be able to make an accurate ſcore, and from the ſcore to figure the baſe, in ſuch a manner as to include all the accidents of modulation. "Without theſe qualifications," ſays M. Walther, in his Muſical Lexicon, "as a German organiſt is not gifted with univerſal knowledge, no perfect harmony can be hoped."

In the market towns and villages of Thuringia, in Saxony, where two perſons are uſually employed in a ſchool, he who directs the muſic in the choir, or leads the pſalm or chorus, is called rector or ſchoolmaſter, and the organiſt is commonly cantor.

CANTRED, or Cantref, denotes a diſtrict or diviſion of an hundred towns or villages. The word is Britiſh, compounded of *cant*, hundred, and *trev*, or *tref*, town or *village*.

Wales, with regard to its leſſer diviſions, ſeems to have been originally divided into "bóds," "trevs," and "caers." The "bôd" is ſuppoſed to have been the manſion-houſe of a chieftain on his firſt ſettlement in the country; the lands which he aſſigned for the maintenance of his dependants in the increaſing colony were called a "trev;" and the incloſure of ſuch lands for defence or convenience, formed either of wood or ſtone, might have been denominated a "caer." An aſſemblage of ſeveral "bóds," formed a "trev" or townſhip; and a hundred of theſe "trevs" conſtituted a "cantrev." For the more eaſy and regular diſpatch of buſineſs, a "cantrev" was divided into two or more "commots;" each of which conſiſting of a certain number of "bóds" and "trevs" formed a diſtinct precinct, and was conſidered as a lordſhip, poſſeſſing a ſeparate court and juriſdiction. Angleſey, in particular, was divided into three "cantrevs" or "cantreds," which are each ſubdivided into ſix "commots" or "commotes," each "commote" containing about ſixty "trevs" or townſhips. The general partition of Wales into "cantrevs" and "commots" is very ancient. Rowl. Monaſt. Ant. Eſſ. § x. p. 110, &c.

CANTU, in *Geography*, a town of Italy, in the Mileneſe; 5 miles S.S.E. of Como.

CANTUA, in *Botany*, (the Peruvian name) Lam. Enc. vol. 1. p. 603. Illuſt. 303. Wild. 324. Juſſ. 136. Vent. vol. ii. 401. Claſs and order, *pentandria monogynia*. Nat. ord. *Polemonia*, Juſſ. Gen. Ch. *Cal.* Perianth one-leafed, tubular, rather ſhort, permanent, five, ſometimes three-cleft; ſegments acutely egg-ſhaped, nearly equal. *Cor.* monopetalous, funnel-ſhaped; tube cylindrical, longer than the calyx; border nearly equal, erect, but a little ſpreading, five-lobed; lobes ſhort, obtuſe. *Stam.* Filaments five, equal, inſerted into the tube of the corolla; anthers egg-ſhaped, ſmall, verſatile. *Piſt.* Germ ſuperior, oblong-egg-ſhaped; Style thread-ſhaped, about the length of the ſtamens; ſtigma trifid. *Peric.* Capſule oblong-egg-ſhaped, cloathed at its baſe with the calyx, three-celled, three-valved, opening at the top: valves oppoſite to the partitions. *Seeds* numerous, egg-ſhaped, winged, affixed to a central, triangular receptacle.

Eſſ. Ch. Corolla monopetalous, funnel-ſhaped. Stamens with equal filaments. Capſules three-celled. Seeds winged. Nearly allied to Bignonia.

Sp. 1. C. *pyrifolia*, Lam. Ill. Pl. 105. *fig.* 1. "Flowers terminal; ſtamens longer than the corolla; leaves egg-ſhaped, petioled, entire, ſmooth." Willd. A ſhrub, ſmooth in all its parts. *Branches* woody, thick, ſtiff, marked with ſcattered tubercles or knots. *Leaves* an inch and a half long, and near an inch broad; alternate; petioles ſhort, proceeding from the tubercles. *Flowers* peduncled, in terminal racemes; calyx often three-cleft, and divided more deeply on one ſide. Found in Peru by Joſeph de Juſſieu. 2. C. *buxifolia*, Lam. Ill. pl. 106. *fig.* 2. "Flowers terminal; ſtamens ſhorter than the corolla; leaves oblong, nearly ſeſſile, entire, pubeſcent beneath." Willd. A ſhrub. *Branches* woody, rather cylindrical, pubeſcent towards their ſummit. *Leaves* ſmall, about ſix lines long, and little more than two broad, alternate or faſciculated, lanceolate-egg-ſhaped, entire. *Flowers* large, peduncled, upright; peduncles and calyx pubeſcent; corolla tubular, an inch and half long. Found in Peru by Joſeph de Juſſieu. 3. C. *Hoitzia*, Willd. (Hoitzia mexicana; Lam. Encyc. Juſſ.) "Flowers axillary; ſtamens longer than the corolla; leaves egg-ſhaped, ſeſſile, toothed." Willd. *Stem* a little ſhrubby; branches ſlender, cylindrical, pubeſcent, eſpecially near their ſummit. *Leaves* alternate, entire near their baſe, a little nerved underneath. *Flowers* of a fine red colour, ſolitary, nearly ſeſſile, on the upper part of the branches; ſegments of the calyx acute: bractes ſix, lanceolate, a little longer than the calyx, and ſurrounding it in the form of an exterior calyx, ſharply toothed, and terminated by a ſpinous point; tube of the corolla four or five times longer than the calyx, ſlightly curved. *Fruit* not known. A native of Mexico. Willdenow juſtly obſerves that as it differs from Cantua only in its bractes, it ought not to conſtitute a diſtinct genus. 4. C. *pinnatifida*, Lam. Ill. (c. coronopifolia, Willd. Polemonium rubrum, Linn. Sp. Pl. Ipomœa rubra, Syſt. veg. Quamoclit pinnatum erectum, Dill. Elth. tab. 241. *fig.* 312.) "Flowers terminal; ſtamens the length of the corolla; leaves pinnatifid." *Stem* ſomewhat ſhrubby, upright, not milky. Tube of the *calyx* ſhort; ſegment of its border awl-ſhaped, longer than the tube. *Stamens* inſerted into the middle of the tube of the corolla without valves. A native of ſandy ſoil in Carolina. Four other ſpecies are figured by Ruiz and Pavon in the Flora Peruvienſis, and three more by Cavanilles in his Icones Plantarum.

CANTWELL, Andrew, in *Biography*, born at Tipperary in Ireland, but lived principally in Paris, where he was made doctor in medicine in 1742. The ſame year he publiſhed a tranſlation into French of the account of Mrs. Stephens' medicine for diſſolving the ſtone in the bladder; and in 1746 an account of ſir Hans Sloane's medicines for diſeaſes of the eyes; alſo ſome ſevere ſtrictures on the practice of propagating the ſmall pox by inoculation; and in the Philoſophical Tranſactions, London, N° 453, an account of a double child, a boy. He died at Paris, July 11, 1764. Haller. Bib. Anat. Eloy Dict. Hiſt.

CANTY Bay, in *Geography*, ſometimes called New bay, lies on the coaſt of Java in the Eaſt Indies, and is formed by an iſland of the ſame name. It furniſhes the beſt accommodation for wooding and watering in theſe ſeas.

CANTYRE. See Kintyre.

CANVAS, or Canvass, in *Commerce*, a coarſe ſort of linen or hempen cloth, uſually woven open, and regularly, in little ſquares; ſerving for divers domeſtic purpoſes, and eſpecially for the ground of tapeſtry work and painting.

We have divers ſorts and denominations of canvas, moſt of them imported from abroad; as Dutch, Barras, and Heſſian canvas; packing canvas; guttings and ſpruce canvas; poledavies, ebbing, or Queenſbrough canvas; working canvas, for botts or cuſhions, narrow, broad, and broadeſt.

Canvas alſo is the cloth on which painters uſually draw their pictures; the canvas being ſmoothed over with a ſlick-ſtone, then ſized, and afterwards whited over, makes what the painters call their *primed cloth*, on which they draw their firſt ſketches with a coal or chalk, and afterwards finiſh with colours.

Canvas is alſo a name ſometimes given to ſail cloth.

Canvas-*bags*, in the *Military Art*, contain about a cubic foot of earth or ſand, with which they are filled. Their uſe is to raiſe a parapet in haſte, or to repair one when beaten down. See Sacks *of earth*.

Canvas is alſo uſed among the French, for the model or firſt words, whereon an air, or piece of muſic, is compoſed, and given to a poet to regulate and finiſh. The canvas of a ſong contains certain notes of the compoſer, which ſhew the poet the meaſure of the verſes he is to make. Thus Du Lot ſays, he has canvas for ten ſonnets againſt the Muſes.

CANUCCIS, in *Ancient Geography*, the ſtation of a Roman colony in Africa, planted there by Auguſtus, about 7 miles W. from Jol; the Gunugi of Ptolemy, and Gunagus of the Itinerary, and correſponding to the Breſk of the Algerines. See Bresk.

CANVEY, in *Geography*, a ſmall iſland in the mouth of the Thames, near the coaſt of Eſſex, about 5 miles long and 2 wide; high tides often overflow the loweſt parts of it: 5 miles N.W. from the Nore.

CANULA. See Cannula.

CANUS, in *Zoology*, a South American ſpecies of Coluber, diſtinguiſhed by having 188 abdominal plates, and 70 caudal ſcales. Linn. Muſ. ad. Fr.

This ſnake is deſcribed by Boddaert as being of a hoary colour, with large whitiſh ſpots diſpoſed ſerrately, with a ſnowy white ſpot between each. The ſnout is obtuſe and rounded; head imbricated with ſcales. It is conceived that this ſpecies ought to be conſidered as a connecting link between the two genera Boa and Coluber.

CANUSIUM. See Canosa.

CANUTE, ſurnamed "the Great," in *Biography*, king of Denmark and England, ſucceeded his father Sweyn in the firſt kingdom, about the year 1014; and commenced his reign with the invaſion of England and Norway, both which kingdoms had revolted from his father. England, however, was his principal object; and as the Engliſh had recalled Ethelred their king, who had abdicated the throne, he was not unapprehenſive that this event might lead to an attempt for rendering him independent of the crown of Denmark. Accordingly he prepared for an invaſion of the kingdom, and ſoon appeared with a fleet off the eaſtern coaſt, which he ravaged with mercileſs fury; putting aſhore all the Engliſh hoſtages at Sandwich, after having cut off their hands and noſes. His abſence, however, had afforded Olaus king of Norway an opportunity of invading his kingdom, and he was under a neceſſity of returning home in order to check his progreſs. This enterpriſe having been completely accompliſhed, he reſumed his attack on England, and made great depredations on the ſouthern coaſt, where an army was aſſembled againſt him, under the command of prince Edmund and duke Edric, the ſon-in-law of Ethelred, who was a notorious traitor. Edric ſtill continued his perfidious machinations; and after endeavouring in vain to get the prince into his power, he found means to diſperſe the army; and he then openly deſerted to Canute with 40 veſſels. When prince Edmund, called "Ironſide," ſucceeded his father Ethelred, he contended gallantly againſt Canute and his confederates; but after the loſs of two battles, occaſioned chiefly by the falſehood and treachery of Edric, he was obliged to acquieſce in a treaty, which divided the kingdom between him and Canute. The latter reſerved to himſelf the northern diviſion, conſiſting of Mercia, Eaſt Anglia, and Northumberland, which he had entirely ſubdued; and the ſouthern parts were reſerved for Edmund. This prince ſurvived the treaty about a month; and his murder, by the accomplices of Edric, made way for the ſucceſſion of Canute to the crown of England, A.D. 1017. Againſt his valour and activity and the ſtrong force which he commanded, the two ſons of Edmund could make but an ineffectual reſiſtance; however, Canute, before he ſeized the dominions of the young princes, ſummoned a general aſſembly of the ſtates in order to ſecure to himſelf the ſucceſſion of the kingdom. In order to maintain the unmoleſted poſſeſſion of the throne, he gratified ſome of the nobility with extenſive governments and juriſdiction, and others, on whoſe fidelity he could not rely, he put to death. Among the latter was the perfidious Edric. His Daniſh followers were liberally recompenſed by means of the heavy taxes which were laid on the people, and particularly on the inhabitants of London, who were thus retaliated for their affection to Edmund and their reſiſtance to the Daniſh power in two obſtinate ſieges. In one of theſe ſieges he diverted the courſe of the Thames, and thus by a new channel brought his ſhips above London-bridge. Canute, having by the concurrence of art and power eſtabliſhed himſelf upon the throne, determined, with the ſoundeſt policy, to reconcile his Engliſh ſubjects to the Daniſh yoke, by the juſtice and impartiality of his adminiſtration. Accordingly, he ſent back to Denmark as many of his followers as he could ſpare; he reſtored the Saxon cuſtoms in a general aſſembly of the ſtates; he made no diſtinction between the Danes and Engliſh in the diſtribution of juſtice; and he took care by a ſtrict execution of law, to protect the lives and property of all his people. In proceſs of time the Danes were gradually incorporated with his new ſubjects. For the greater ſecurity of his government he contrived to remove the two ſons of Edmund to Hungary; and, to conciliate the Normans, who eſpouſed the cauſe of Alfred and Edward, the ſons of Ethelred, he married Emma, the mother of theſe princes and the ſiſter of Richard, Duke of Normandy.

Canute, having ſettled his power in England beyond the danger of a revolution, made a voyage to Denmark, for the purpoſe of reſiſting the attacks of Oſmund, king of Sweden; and in this expedition he was accompanied by a great body of the Engliſh, under the command of the earl Godwin. The earl, by his ſkill and valour, contributed to the total diſcomfiture of the Swediſh army, and ſo effectually recommended himſelf to Canute, as not only to obtain his daughter in marriage, but to lay the foundation of that immenſe fortune which afterwards accrued to his family. Canute, availing himſelf of this advantage, paſſed with ſuch celerity to Schonen, that he ſurpriſed, defeated, and ſlew in battle the king of Sweden. In another voyage, which he made afterwards to Denmark, he attacked Norway, and expelling the juſt, but unwarlike Olaus, kept poſſeſſion of his kingdom till the death of that prince. Canute was now one of the moſt powerful ſovereigns in Europe; extending his empire over Denmark, Norway, and England, and having rendered Sweden tributary. But neither the elevation of his rank, nor the extent of his dominion, could bound the graſp of his capacious and aſpiring mind. Experience taught him the unſatisfactory nature of all terreſtrial enjoyments; and he began to direct his views towards that future exiſtence, which it is ſo natural for the human mind, whether ſatiated by proſperity or diſguſted with adverſity, to make the object of its attention. The ſpirit of the age in which he lived, however, gave a wrong direction to his devotion; and inſtead of making compenſation to thoſe whom he had injured by his former acts of violence, he employed himſelf entirely in thoſe exerciſes of piety, which the monks repreſented as the moſt meritorious. He built churches, endowed monaſteries, enriched eccleſiaſtics, and beſtowed revenues for the ſupport of chantries, in various places, where he appointed prayers to be ſaid for the ſouls of thoſe who had there fallen in battle againſt him. He even undertook a pilgrimage to Rome, where he reſided a conſiderable time, and where he obtained from the pope ſome privileges for the Engliſh ſchools erected in that capital, and exemptions from thoſe impoſitions and tolls which the Engliſh pilgrims had been accuſtomed to pay in the countries through which they paſſed. It is natural to imagine that a ſovereign, ſo proſperous and powerful, ſhould meet with adulation from his courtiers. A ſingular, but well known, inſtance of this kind occurs in the caſe of Canute. Some of his flatterers, when they were one day expreſſing their admiration of his grandeur and dominion, ſaid to him, that nothing was beyond the reach of his power: upon which the monarch, it is ſaid, ordered his chair to be ſet on the ſea-ſhore, while the tide was riſing; and as the waters approached, he commanded them to retire, and to obey the voice of him who was lord of the ocean. He feigned to ſit ſome time in expectation of their ſubmiſſion; but when the ſea ſtill advanced towards him, and began to waſh him with its billows, he turned to his courtiers, and remarked to them, that every creature in the univerſe was feeble and impotent, and that power reſided with one Being alone, in whoſe hands were all the elements of nature; who could ſay to the ocean, "Thus far ſhalt thou go, and no farther;" and who could level with his nod the moſt towering piles of human pride and ambition. The only memorable action which Canute performed, after his return from Rome, in 1031, was an expedition againſt Malcolm, king of Scotland, who had refuſed to render him homage for the county of Cumberland, which he held as vaſſal to the crown of England. Upon his appearing on the frontiers with a formidable army, Malcolm ſubmitted, and agreed, that his grandſon and heir, Duncan, whom he put in poſſeſſion of Cumberland, ſhould make the ſubmiſſions required, and that the heirs of Scotland ſhould always acknowledge themſelves vaſſals to England for that province. After this enterpriſe Canute paſſed four years in peace, and died at Shafteſbury, in 1035; leaving three ſons, Sweyn, Harold, and Hardicanute, and appointing, by his will, Harold ſucceſſor to the Engliſh crown. Mod. Un. Hiſt. vol. xxviii. p. 429. Hume's Hiſt. of England, vol. i. p. 145—154.

CANUTI Avis, in *Ornithology*, *tringa canutus*; our common knot is ſo called by ſome old writers.

CANUTUS, in *Ornithology*, a ſpecies of Tringa, known in this country by the name of *knot*. It is a native of various parts of Europe, and of America. The bill is ſmooth; legs inclining to aſh colour; primary quill feathers ſerrated; outermoſt tail-feathers white, and without ſpots. Fn. Suec. Brünnich, &c.

The bill of this bird is duſky aſh-colour; irides hazel; lores duſky; eye-brows and band on the wings white; body cinereous above, beneath white; lower wing-coverts tipt with white; chin and breaſt with minute ſpots; belly and vent with duſky lines.

Canutus, a ſpecies of Tringa, with ſmooth bill; legs inclining to aſh-colour; primary quill feathers ſerrated, exterior tail feathers white and without ſpots. Fn. Suec. Obſ. This is the knot of Engliſh writers, Canutus of Briſſon, and Canut of Buffon. Inhabits Europe and America. Length nine inches; fleſh excellent.

CANY, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton in the diſtrict of Yvetot; the place contains 1432, and the canton 12,157 inhabitants; the territory includes 127½ kiliometres, and 23 communes. The adjacent country produces great quantities of corn and flax. N. lat. 49° 48′. E. long. 0° 32′.

Cany *Fork*, a river of America, in the ſtate of Tenneſſee, which is ſhort and navigable, and runs N. W. into Cumberland river, W. of the Salt-lick and oppoſite Salt-lick creek, 50 miles in a ſtraight line from Naſhville.

CANYTIS, in *Ancient Geography*. See Catytis.

CANZONE, an Italian lyric poem in regular ſtanzas, for which Dante has given precepts and eſtabliſhed the laws. The *canzoni* of Petrarca, and the old poets ſeem to want variety of meaſure, and to be too long ever to have been intended for muſic.

CANZONETTA, is the diminutive of *canzone*, a ſhort lyric poem, and always intended for muſic.

CANZURI, a name given by ſome authors to a peculiar kind of camphor more eſteemed than any other ſort. Some have ſuppoſed it thus called from *Kanzur* or *Chanzur*, the name of a place where they ſuppoſe it to be produced, which ſeems the more probable opinion, though Scaliger rejects it. See Canderros.

CAO-CHAN, in *Geography*, a town of Aſia, in the kingdom of Corea; 30 miles E.S.E. of Hetſin.

CAO-CHAN-LI, a town of Aſia in Corea; 420 miles E. of Peking.

CAOINAN, the name given to the funeral ſong of the Iriſh. Mr. Beauford (Iriſh Tranſ. Vol. IV. p. 46, &c.) has preſented to the curious a ſpecimen of this ſong, with the words in Iriſh and Engliſh, ſet to muſical notes, with its full choruſes of ſighs and groans, and burden of ulla lulla lulla lā. He has alſo prefixed a brief account of the modes of lamentation, by howls, geſtures, and ceremonies, which have prevailed, and which ſtill, in a degree, prevail in Ireland. He ſuppoſes them to have been derived from the primæval inhabitants of Ireland, of Celtic race. Theſe, he ſays, were a timorous and unwarlike race, as their military weapons, and every veſtige of their cuſtoms and manners ſtrongly indicate: their religion alſo was ſpiritual and untainted with human blood. Such a religion and ſuch manners imply a ſuſceptibility of tender impreſſions, and feminine expreſſions of ſorrow. Accordingly, it has been affirmed of the Iriſh, that to cry was more natural to them than to any other nation, and at length the Iriſh cry became proverbial. Cambrenſis, in the 12th century, informs us, that the Iriſh then muſically expreſſed their grief, or applied the muſical art, in which they are ſaid to have excelled all others, to the orderly celebration of funeral obſequies, by dividing the mourners into two bodies, each alternately ſinging their part, and the whole, at times, joining in full chorus. This antiphonal ſinging is ſaid to have been coeval with Chriſtianity in this iſle. See Antiphony. It was then the funeral elegy roſe in poetic numbers, and was ſung in poetic accents to the ſound of muſical inſtruments. After the body of the deceaſed, dreſſed in grave cloths, and ornamented with flowers, was placed on a bier, or ſome elevated ſpot, the relatives and "Keeners" ranged themſelves in two diviſions, one at the head and the other at the feet of the corpſe. The funeral caoinan having been previouſly prepared by the bards and "croteries," the chief bard of the head chorus began, by ſinging the firſt ſtanza in a low doleful tone, which was ſoftly accompanied by the harp: at the concluſion, the foot ſemi-chorus began the lamentation of "ullaloo," from the final note of the preceding ſtanza, in which they were anſwered by the head ſemi-chorus; theſe both united in one general chorus. The chorus of the firſt ſtanza being ended, the chief bard of the foot ſemi-chorus ſung the ſecond ſtanza, the ſtrain of which was taken from the concluding note of the preceding chorus; which ended, the head ſemi-chorus began the ſecond "gol" or lamentation, in which they were anſwered by that of the foot, and then, as before, they united in the general full chorus. Theſe alternately were the ſong and choruſes performed during the night: the genealogy, rank, poſſeſſions, virtues, and vices of the dead were rehearſed; and various interrogations were addreſſed to the deceaſed. Each verſicle of the Caoinan, it is ſaid, conſiſted only of four feet, and each foot was commonly of two ſyllables; the three firſt required no correſpondence, but the fourth was to correſpond with the terminations of the other verſicles. This kind of artificial metre was much cultivated by the Iriſh bards; but, on the decline of that order, the caoinan was aſſumed by women, and became an extemporaneous performance. Each province was ſuppoſed to have different caoinans, and hence the Munſter cry, the Ulſter cry, &c. which are only different imitations of the different choruſſes of the ſame caoinan, independent of provincial diſtictions. As the caoinan was ſung extempore, and had no genuine eſtabliſhed time, each ſet of "Keeners" varied the melody according to their taſte and muſical abilities, carefully preſerving, however, the ſubject or burden of the ſong throughout, both in the vocal and inſtrumental part; as begun by the leading "Keener." The caoinan is at preſent much neglected; and this ancient cuſtom will probably ſoon ceaſe; Engliſh manners and the Engliſh language ſupplanting that of the aboriginal natives. At the concluſion of the "Keenan," the body was conveyed to the place of interment, attended by the friends and relatives of the deceaſed, and accompanied by the cries of women, who at certain intervals ſung the "gol" or "ullaloo." In ancient times, after the interment, the favourite bards of the family, ſeated on the grave or ſepulchre, performed the "connthal" or elegy; which they repeated every new and full moon, for the firſt three months, and afterwards generally once every year, for perſons of diſtinction. The elegy was more regular than the "keenan," both in reſpect to its poetical compoſition and concluding cadence. The families, both in Wales and Ireland, retained this cuſtom to the cloſe of the laſt century, and it is frequently alluded to in the Iriſh ballads and poetical romances.

CAO-LIM, in *Geography*, a town of Aſia in Corea; 600 miles E.N.E. of Peking. N. lat. 42° 40′. E. long. 129° 29′.—Alſo, a town of Chineſe Tartary. N. lat. 42°. E. long. 123° 54′.

CAO-MING, a town of China, of the ſecond rank, in the province of Yunan. N. lat. 25° 22′. E. long. 102° 44′.

CAO-TANG, a town of China, of the ſecond rank, in the province of Chantong; 200 miles S. of Peking. N. lat. 36° 58′. E. long. 115° 54′.

CAO-TCHIN, a town of China, of the third rank, in the province of Pet-cheli; 15 miles E.S.E. from Tching-ting.

CAO-Y, a town of China, of the third rank, in the province of Pet-cheli; 30 miles S. of Tching.

CAO-YAM, a town of China, of the third rank, in the province of Pet-cheli; 12 miles S. of Gan.

CAO-YANG, a town of Aſia, in the kingdom of Corea; 7 miles N.W. of King-kitaſo.

CAO-YUEN, a town of China, of the third rank, in the province of Chang-tong; 42 miles N.W. of Tchintcheou.

CAORLO, a town of Italy, on an iſland of the ſame name, in the gulf of Venice, near the coaſt of Friuli; the ſee of a biſhop, ſuffragan of Venice. N. lat. 45° 54′. E. long. 12° 44′.

CAOUANNA, in *Zoology*, *Caouanne* of Ray; *teſtudo caretta* of modern naturaliſts, and logger-head turtle of Cateſby. The fleſh of this ſpecies is highly rancid, harſh, tough, and ſtringy. See Testudo Caretta.

CAOUKE, in the *Turkiſh Dreſs*, a high ſtiff turban, worn by the odabaſhees, or heads of the chambers of janizaries, when they go in proceſſion.

CAOUTCHOUC, *Elaſtic Gum*, in *Chemiſtry*. This ſingular vegetable ſubſtance was firſt brought to Europe from South America, about the beginning of the laſt century. Nothing however was known concerning its natural hiſtory till a memoir was preſented in 1736 to the French academy by Condamine, in which it is ſtated, that there grows in the province of Eſmeraldas in Braſil, a tree called by the natives "Hhevé, from the bark of which, when wounded, there flows a milky juice, which by expoſure to the air, is converted into caoutchouc. Some time after, the ſame tree was found in Cayenne by M. Freneau ; and it appears from later reſearches, that this ſingularly elaſtic ſubſtance is procured from at leaſt two trees natives of South America : of theſe, the one is called by botaniſts hævea caoutchouc, and the other, jatropha elaſtica. The American caoutchouc is uſually brought to Europe in the form of globular narrow necked bottles, about a fourth of an inch thick, and capable of holding from half a pint to a quart or more. They are formed upon moulds of unburnt clay, pieces of which are often found adhering to the inſide. In its native country it is fabricated by the inhabitants into veſſels for containing water and other liquids, and on account of its inflammability, it is uſed at Cayenne for torches.

In the Aſiatic reſearches is an account by Mr. Howiſon, ſurgeon at Pulo Penang, of a ſubſtance exhibiting all the properties of caoutchouc, procured from the juice of a climbing plant, the urceola elaſtica, a native of that ſmall iſland, and the neighbouring coaſt of Sumatra. If one of the thicker and older ſtems of this plant is cut into, a white juice oozes out, of the conſiſtence of cream, and ſlightly pungent to the taſte. By expoſure for a ſhort time to the action of the air, or ſtill more expeditiouſly by the addition of a few drops of acid, a decompoſition takes place ; the homogeneous thick cream-like juice, ſeparates into a thin whitiſh liquor, reſembling whey, and the caoutchouc concretes into a clot or curd, covered ſuperficially with a thin coating of a butyraceous ſubſtance. If the juice as ſoon as ſecreted is carefully excluded from the air, it may be preſerved for ſome weeks without any material change, but at length the caoutchouc ſeparates from the watery part in the ſame manner, though not ſo perfectly as it does by free expoſure to the air. The proportion of caoutchouc contained in the juice by the oldeſt ſtems, is nearly equal to two thirds of its weight ; the juice from the younger trees is much more fluid, and contains a conſiderably ſmaller proportion of this ſubſtance.

According to the experiments of Mr. Howiſon, cloth of all kinds may be made impenetrable to water by impregnating it with the freſh juice of the urceola ; and the pieces thus prepared are moſt effectually and expeditiouſly joined together by moiſtening the edges with the entire juice, or even the more watery part, and then bringing them in contact with each other. Boots, gloves, &c. made of this impervious cloth are preferable even to thoſe formed of pure caoutchouc, as they are more durable and retain their ſhape better. If a ſufficient quantity of this juice could be obtained, it might no doubt be applied to a vaſt variety of important purpoſes.

The colour of freſh caoutchouc is yellowiſh white, but by expoſure to the air it becomes of a ſmoak grey. American caoutchouc, in the ſtate in which it is brought to Europe, being formed of a multitude of extremely thin layers, each of which is expoſed to the air for ſome time in order to dry before the next is laid on, is of a yellowiſh ſmoak-grey colour throughout, but maſſes of Eaſt Indian caoutchouc being formed more expeditiouſly, are dark-coloured only on the outſide ; when cut into, they are of a very light brown, which however ſoon deepens by the action of the air. Caoutchouc is perfectly taſteleſs, and has little or no ſmell, except when it is warmed ; it then gives out a faint peculiar odour. The elaſticity of this ſubſtance is very remarkable, and indeed is one of its moſt characteriſtic properties. Slips of caoutchouc when ſoftened by immerſion for a few minutes in boiling water, may be drawn out to ſeven or eight times their original length, and will afterwards reſume very nearly their former dimenſions. During its extenſion, a very ſenſible warmth is produced, as may be perceived if the piece is held between the lips ; and on the contrary, when it is allowed to contract, a decreaſe of temperature will immediately take place. By ſucceſſive extenſions and contractions, eſpecially in cold water, its elaſticity is much impaired ; but if in this ſtate it is immerſed for a time in hot water, it reabſorbs the caloric which it had loſt, returns to its original ſize, and recovers its primitive elaſticity. At the temperature of about 40° Fah. caoutchouc begins to grow rigid, its colour becomes much lighter, and it is nearly opaque, and as the cold increaſes, it becomes ſtill more ſtiff and harder. Theſe changes, however, depend merely on temperature, for a piece of hard frozen caoutchouc again reſumes its elaſticity on being warmed. The freſh cut ſurfaces of this ſubſtance will unite together by ſimple contact, and by a proper degree of preſſure, may be brought ſo completely in union as to be no more liable to ſeparate in this part than in any other. Its ſp. gr. according to Briſſon is 0.933. It undergoes no alteration by the action of the air at the common temperature. When boiled for a long time in water it communicates to this fluid a peculiar ſmell and flavour, and is ſo far ſoftened by it, that two pieces thus treated, and afterwards ſtrongly preſſed, will form a permanent adheſion to each other.

When heated to a temperature nearly equal to that of melting lead, caoutchouc runs into a black viſcid fluid of the conſiſtence of tar, which does not concrete on cooling, neither does it dry by long expoſure to the air. When held to a candle it readily takes fire, and burns with a copious white flame, and a large quantity of dark coloured ſmoak, exhaling at the ſame time a peculiar, but not unpleaſant odour : from its ſmoak a conſiderable quantity of very fine lamp-black may be collected. In dry diſtillation it gives out ammonia and carbonated hydrogen.

Concentrated ſulphuric acid, when heated, acts with great energy on caoutchouc, reducing it to a black friable carbonaceous ſubſtance, the acid at the ſame time being in part decompoſed, and ſulphureous acid being produced. When treated with nitric acid, azotic gas and carbonic and pruſſic acid are diſengaged, oxalic acid is left in ſolution, and the reſidue is converted into a yellow friable maſs. By digeſtion in oxymuriatic acid the colour of caoutchouc is diſcharged, it becomes opaque, indurated, and wrinkled, like tanned leather, but appears to undergo no other change. Similar effects are produced, though more ſlowly, by muriatic acid.

Ammoniacal gas, according to Dr. Thomſon, is abſorbed by caoutchouc, and converts it into a ſoft, glutinous, and inelaſtic ſubſtance. The ſame able chemiſt alſo ſtates, that the cauſtic fixed alkalies are capable of combining with, and diſſolving it. Caoutchouc is alſo ſoluble with eaſe at a boiling heat in the expreſſed vegetable oils, in wax, butter, and animal oils, forming viſcid inelaſtic compounds. Alcohol appears not to have the ſmalleſt action on it either cold or hot.

Rectified oil of turpentine, at the common temperature, acts without difficulty on caoutchouc, firſt rendering it tranſparent, and enlarging its bulk conſiderably, and in the courſe of a few days, effecting a complete ſolution. This compound is of the conſiſtence of drying oil, and when ſpread thin on wood, it forms a varniſh which however is a long time in becoming quite dry. When mixed with a ſolution of wax in boiled linſeed oil, it compoſes an elaſtic varniſh which is uſed for covering balloons.

The only menſtrua for this ſubſtance, from which it can be ſeparated again unaltered, are ether, naphtha, and cajeput oil.

The ſolubility of caoutchouc in ether was firſt diſcovered by Macquer, a circumſtance which from its frequent failure in the hands of other chemiſts, was very generally called in queſtion, till Cavallo cleared up the difficulty by ſhowing the neceſſity of employing waſhed ether for this purpoſe. If rectified ſulphuric ether is ſhaken in a vial with ſome pure water, it diſſolves about a tenth of its weight of this latter ſubſtance, and in this ſtate is capable of effecting a complete and ſpeedy ſolution of caoutchouc. The ſolution is of a light brown colour, and when ſaturated, is conſiderably viſcid. A drop of it let fall into a cup of water immediately extends itſelf over the whole ſurface; and the ether being partly abſorbed by the water, and partly evaporated, the water is found covered with an extremely thin film of caoutchouc, poſſeſſing its elaſticity, and all its other characteriſtic properties. A ſimilar effect takes place when cloth of any kind is ſoaked in the ſolution, or any hard ſurface is ſmeared over with it; on expoſure to the air the ether is rapidly evaporated, and the caoutchouc which it was combined with is left behind. The affinity of this ſolution for caoutchouc is very great: if the edges of two pieces of caoutchouc are dipped in it and immediately brought in cloſe contact with each other, as ſoon as the ether is evaporated, they will be found to be perfectly united.

There are two circumſtances which muſt always prevent the extenſive uſe of the ethereous ſolution of caoutchouc, admirably qualified as it is in other reſpects for many uſeful purpoſes; theſe are, firſt, its expenſiveneſs, and ſecondly, the extraordinary rapidity with which the ether evaporates; thus rendering it impoſſible to lay an even coating of this varniſh on any ſurface, and clogging up the bruſhes by which it is applied. In order to form tubes or catheters of this ſubſtance, the beſt method is to cut a bottle of caoutchouc in a long ſingle ſlip, and ſoak it for half an hour or an hour in ether: by this means it will become ſoft and tenacious, and if wound dexterouſly on a greaſed mould, bringing the edges in contact with each other at every turn, and giving the whole a moderate and equal preſſure by binding it with a tape wound in the ſame direction as the caoutchouc, a very effectual union will be produced; after a day or two, the tape may be taken off and the cylinder of caoutchouc may be rendered ſtill more perfect by pouring a little of the etherous ſolution into a glaſs tube cloſed at one end, the diameter of which is a little larger than that of the cylinder of caoutchouc; which being introduced into the tube, will force the ſolution to the top of the veſſel. Let the whole of the apparatus be then placed in boiling water; the ether will be evaporated, and a ſmooth and uniform coating of newly depoſited caoutchouc will remain upon the cylinder.

Petroleum when rectified by gentle diſtillation, affords a colourleſs liquid not to be diſtinguiſhed from the pureſt naphtha, and this, according to Fabbroni, has the property of diſſolving one ſeventieth of its weight of caoutchouc, and of depoſiting it again unaltered by ſpontaneous evaporation. It does not appear, however, that this menſtruum has been much employed.

The ſolubility of caoutchouc in cajeput oil was firſt noticed by Dr. Roxburgh. This is an eſſential oil procured in India, by diſtillation, from the leaves of the *Melaleuca Leucadendron.* The ſolution is very thick and glutinous; and is decompoſable by alcohol, this latter uniting with the eſſential oil and leaving the caoutchouc floating on the liquor in a ſoft ſemifluid ſtate. This on being waſhed with alcohol, and expoſed to the air, becomes as firm and elaſtic as before it was diſſolved; while in the intermediate ſtate between fluid and firm, it may be drawn out into long tranſparent threads, reſembling in the poliſh of their ſurface, the fibres of the tendons of animals, and ſo extremely elaſtic, that when broken, each end immediately returns to its reſpective maſs. Through all theſe ſtages the leaſt preſſure with the finger and thumb is capable of uniting different portions as completely as if they had never been ſeparated, and that without any clammineſs or ſticking to the fingers.

The uſes to which caoutchouc has been hitherto applied, are the following. It is chiefly uſed for rubbing out black lead-pencil marks from paper, whence its vulgar name Indian rubber: it is of value to the chemiſt as a material for flexible tubes to gazometers and other apparatus; the ſurgeon is indebted to it for flexible ſyringes and catheters; and finally it enters as an eſſential ingredient into the compoſition of the beſt varniſh for balloons.

Caoutchouc *Vine*, in *Botany*, a ſpecies of *Urceola*, which ſee.

CAP, a garment ſerving to cover the head, and made nearly of its figure.

The æra of caps and hats is referred to the year 1449, the firſt ſeen in theſe parts of the world being at the entry of Charles VII. into Rouen; from that time they began, by little and little, to take place of the hoods or chaperoons, that had been uſed till that period. M. le Gendre, indeed, goes farther back; they began, ſays he, under Charles V. to let fall the angles of the hood upon the ſhoulders, and to cover the head with a cap, or bonnet: when this cap was of velvet, they called it *mortier:* when of wool, ſimply *bonnet:* the firſt was laced, the latter had no ornament, beſides two horns, raiſed to a moderate height, one of which ſerved in covering and uncovering. None but kings, princes, and knights, were allowed the uſe of the *mortier*.

The cap was the head-dreſs of the clergy and graduates. Paſquier ſays, that it was anciently a part of the hood worn by the people of the robe; the ſkirts whereof being cut off, as an incumbrance, left the round cap an eaſy commodious cover for the head; which round cap being afterwards aſſumed by the people, thoſe of the gown changed it for a ſquare one, firſt invented by a Frenchman, called Patrouillet: he adds, that the giving of the cap to the ſtudents in the univerſities, was to denote, that they had acquired full liberty, and were no longer ſubject to the rod of their ſuperiors; in imitation of the ancient Romans, who gave a *pileus*, or cap, to their ſlaves, in the ceremony of making them free: whence the proverb, *Vocare ſervos ad pileum.* Hence alſo on medals, the cap is the ſymbol of liberty, whom they repreſent holding a cap in her right hand, by the point. When this cap was expoſed to the view of the people, on the top of a ſpear, as in the caſe of the conſpiracy which had occaſioned the death of Cæſar, it was intended as a public invitation to the people, to embrace the liberty that was offered to them by the deſtruction of their tyrant. This thought of the conſpirators on occaſion of this event, was not new; for Saturninus, in his ſedition, when he had poſſeſſed himſelf of the Capitol, exalted a cap on the top of a ſpear, as a token of liberty to all the ſlaves, who would join with him; and though Marius, in his ſixth conſulſhip, deſtroyed him for that act, by a decree of the ſenate, yet he himſelf uſed the ſame expedient afterwards to invite the ſlaves to take arms with him againſt Sylla, who was marching with his army into the city to attack him. Val. Max. viii. 6.

The Romans were many ages without any regular covering for the head: when either the rain or ſun was troubleſome, the lappet of the gown was thrown over the head; and hence it is that all the ancient ſtatues appear bareheaded, excepting ſometimes a wreath, or the like. And the ſame uſage obtained among the Greeks, where, at leaſt during the heroic age, no caps were known. The ſorts of caps or covers of the head in uſe among the Romans on divers occaſions, where the *pitra*, *pileus*, *cucullus*, *galerus*, and *palliolum*, the differences between which are often confounded by ancient as well as modern writers.

The French clergy wear a ſhallow kind of cap, called Calotte, which only covers the top of the head, made of leather, ſattin, worſted, or other ſtuff. The red cap is a mark of dignity allowed only to thoſe who are raiſed to the cardinalate. The ſecular clergy are diſtinguiſhed by black leathern caps, the regulars by knit and worſted ones.

The Chineſe have not the uſe of the hat, like us; but wear a cap of a peculiar ſtructure, which the laws of civility will not allow them to put off: it is different for the different ſeaſons of the year; that uſed in ſummer, is in form of a cone, ending at top in a point. It is made of a very beautiful kind of mat, much valued in that country, and lined with ſattin: to this is added, at top, a large lock of red ſilk, which falls all round as low as the bottom; ſo that, in walking, the ſilk fluctuating regularly on all ſides, makes a graceful appearance: ſometimes, inſtead of ſilk, they uſe a kind of bright red hair, the luſtre whereof no weather effaces. In winter they wear a pluſh cap, bordered with martlet's, or fox's ſkin; as to the reſt, like thoſe for the ſummer. Nothing can be neater than theſe caps; they are frequently ſold for eight or ten crowns; but they are ſo ſhort that the ears are expoſed.

The cap or bonnet is a mark or ornament of certain characters: thus churchmen, and the members of univerſities, ſtudents in law, phyſic, &c. as well as graduates, wear "ſquare caps." In moſt univerſities, doctors are diſtinguiſhed by peculiar caps, given them in aſſuming the doctorate. Wickliffe calls the canons of his time *biſurcati*, from their caps. Paſquier obſerves, that in his time, the caps worn by the churchmen, &c. were called "ſquare caps," though, in effect, they were round yellow caps.

The cap is ſometimes alſo uſed as a mark of infamy: in Italy the Jews are diſtinguiſhed by a yellow cap; at Lucca by an orange one. In France, thoſe who had been bankrupts were obliged ever after to wear a green cap, to prevent people from being impoſed on in any future commerce. By ſeveral arrets in 1584, 1622, 1628, 1688, it was decreed, that if they were at any time found without their green cap, their protection ſhould be null, and their creditors impowered to caſt them into priſon: but the practice is not now continued.

Cap *of maintenance*, or *Cap of ſtate*, one of the regalia or ornaments of ſtate belonging to the kings of England, before whom it was carried at the coronation and other great ſolemnities; and alſo of the mayors of ſeveral cities in England. It is of crimſon velvet faced up ermine, with two points turned to the back; and was formerly eſteemed a badge and ſymbol of dignity, and ſuitable to a prince of the blood, being worn by king Edward III. and ſucceeding kings of England down to Edward VI.; but of late it hath been granted to private families. It is frequently to be met with above the helmet, inſtead of a wreath, under gentlemen's creſts.

Cap *of a gun*, is a piece of lead which is put over the touch-hole of a gun, to keep the priming from being waſted or ſpilt.

Cap, in a *ſhip*, is a ſquare piece of timber, put over the head, or upper end of a maſt, having a round hole to receive the maſt. By theſe caps, the top-maſts, and top-gallant-maſts, are kept ſteady and firm in the treſſel-trees, where their feet ſtand; as thoſe of the lower-maſts do in their ſteps. Or, a cap is a thick block of elm-timber, with two holes perpendicularly to its length and breadth, and parallel to its thickneſs, (the foremoſt hole being round, and the after one ſquare), uſed to confine two maſts together, when one is erected at the head of the other to lengthen it. The main and foremaſt caps of large ſhips are of elm, and made of two pieces coaked or douled together in the middle; and others are of one ſolid piece. The main cap, in length, is to be four times the diameter of the top-maſt, with the addition of three inches; the breadth is to be twice the diameter, with the addition of two inches; and the depth four-ninths of the breadth. The fore-cap, in length, is to be four times the diameter of its top-maſt, with the addition of two inches; the breadth twice the diameter, with the addition of one inch; and the depth four-ninths of the breadth. The length of the mizen cap is to be four times the diameter of its top-maſt, with the addition of one inch; the breadth, twice the diameter; and the depth four-ninths of the breadth. The caps of yachts and ſimilar veſſels have a ſheave-hole on each ſide for the jeers of the lower yards. If the cap is made of two pieces, the thickneſs of the coak is added to one piece. When the coak is adjuſted, the two pieces are bolted through with ſix bolts, one inch diameter, two at each end, and two in the middle, which are driven from each ſide alternately and clenched on a ring. The holes are ſet off from the centre of the under-ſide of the cap at equal diſtances, and the diſtance between the holes is to be two-fifths of the diameter of the round hole, and half the tapering of the maſt head in its length. The round holes of all caps are leathered and nailed on the upper and lower ſides. In order to allow for the ſhrinking of the caps, the ſize of the tenon is taken $1\frac{1}{2}$ inch above the ſtops, and that is ſet off on the under ſide of the cap; the caps are alſo to be raiſed above a level from the middle-line on the maſt $\frac{1}{4}$ of an inch to a foot in length, in order to allow for their drooping. See Mast, and *Plate of* Ships.

Cap, is alſo a ſemicircular projection from the ſides and round the end of a block, above the pin; through which two holes are bored, obliquely from the ſides, meeting and forming an angle at the end; through theſe holes the ſtrap is paſſed, to prevent its being chafed. See Block.

*To* Cap, is ſaid of a ſhip in the trials of the running or ſetting of currents.

*To* Cap *a rope*, is to cover the end with tarred canvas, which is whipt with twine or ſpun yarn.

Cap, in *Chemiſtry*, ſignifies the piece which terminates the top of a *melting* furnace.

Cap, in *Geography*. See Button *iſland*.

Cap, in *Phytology*, a name given to the huſk or green ſucculent coat which covers the upper part of a nut, and connects it with the parent tree. The cap conſiſts of a pilling and parenchyma derived from the bark, and ramulets from the ligneous body of the branch.

Cap *of a* mushroom, is the head or ſuperior part expanded over the foot ſtalk, ſomewhat in manner of a canopy, or umbrella.

Cap, or *great* Cap, in *Surgery*, a denomination of a kind of compendious bandage, ſerving for almoſt all occaſions of the head, being in figure not unlike a helmet. Among chirurgical inſtruments we met with a ſilver *cap*, *pileolus argenteus*, (though of late alſo made of wood, or even white wax), perforated at both ends, applied to the paps of nurſing women, when ulcerated, for the more commodious giving of ſuck.

Cap, *black*, in *Ornithology*, the pewit, tringa vanellus.

Cap, *black*, alſo the motacilla atricapilla.

Cap, *Neptune's*. See Neptune.

Cap, *prieſt's*, in *Fortification*. See Bonnet *à prêtre*.

Cap-*merchant*, in a trading ſhip, is the ſame officer who is called purſer on board a man of war. The French call him writer (*ecrivain*). He is appointed by the merchant to whom the ſhip belongs, to take care that nothing be embezzled or ſquandered away.

CAPACINI, in *Geography*, a town of Naples, in the province of Capitanata; four miles weſt of Vieſta.

CAPACIO, a town of Naples, in the province of Principato Citra, the ſee of a biſhop, ſuffragan of Salerno; five miles north of Agropoli.

CAPACITY, in a general ſenſe, an aptitude or diſpoſition to retain or hold any thing.

Capacity, in *Geometry*, denotes the ſolid content of any body; and "meaſures of capacity" are our hollow meaſures for wine, beer, corn, ſalt, &c.

Capacity, in *Law*, ſignifies the ability poſſeſſed by an individual, or body politic, to give or take lands, or other things, or to ſue actions. Our law allows the king two capacities, a natural and a political: in the firſt he may purchaſe land to him and his heirs; in the latter, to him and his ſucceſſors. An alien born hath ſufficient capacity to ſue in any perſonal action, and is capable of perſonal eſtate; but he is not capable of lands of inheritance. See **Alien.** Perſons attainted of treaſon or felony, ideots, lunatics, infants, &c. are not capable of making any deed of gift, grant, or conveyance, unleſs in ſome ſpecial caſes. Co. Litt. 171, 172. See Infant, Ideot, &c. All perſons are capable of committing crimes and ſuffering puniſhment, on behalf of whom the want or defect of will cannot be legally pleaded. There are three caſes in which the will does not join with the act, viz. where there is a defect of underſtanding; where there are underſtanding and will ſufficient, but not called forth and exerted by the party poſſeſſing them at the time of the action done, as in the caſe of all offences committed by chance or ignorance; and where the action is conſtrained by ſome outward force or violence. Beſide the caſes comprehended under theſe particulars, there is one more in which the law ſuppoſes an incapacity of doing wrong, from the excellence and perfection of the perſon: this is the caſe of the king, who, by virtue of his royal prerogative, is not under the coercive power of the law; which will not ſuppoſe him capable of committing a folly, much leſs a crime. Blackſt. Com. b. iv. c. 2.

Capacity, in the *Modern Doctrine of Heat*, ſignifies the proportional capability of a given quantity of any ſubſtance to abſorb and retain caloric; or that diſpoſition or property by which various bodies reſpectively require more or leſs of this fluid to ſuperinduce any given temperature in a given maſs. See Caloric and Temperature.

That this capacity varies in different bodies, and even in the ſame ſubſtance in different ſtates, may be eaſily ſhewn. If the quantities of heat neceſſary to be added to or taken from bodies, in order to produce equal changes in their temperature, were in all caſes proportional to their reſpective quantities of matter;—as if, for example, it would require the ſame quantity of this fluid to heat a pound of water, a pound of oil, or a pound of mercury twenty degrees; this would, of courſe, indicate that their capacities were equal: but if, on the contrary, it ſhould be found that the ſame quantity of caloric applied to theſe various ſubſtances ſhould produce different changes in the temperature of equal quantities, or equal changes in the temperature of different quantities of each, it would follow that their capacities for this fluid muſt proportionally vary. Let us conceive that having three ſeveral pounds of water at the temperature of 110° of Fahrenheit's thermometer in ſeparate veſſels, there be added to the firſt a quantity of water at 50°, to the ſecond a quantity of ſpermaceti oil alſo at 50°, and to the third a quantity of mercury at the like temperature of 50°; and that each of the mixtures be ſtirred together, and the addition continued, till they have all aſſumed throughout a common temperature of 70°. Now, as each of the pounds of water has, in this caſe, been deprived of an equal quantity of caloric, (viz. as much as was neceſſary to raiſe its temperature 40°, or from 70° to 110°,) the *abſolute* capacities of the whole of the water, the oil, and the mercury, which have been added, muſt of courſe be equal, whatever be the quantity of each; each of them having abſorbed an equal quantity of heat. On comparing the quantities of theſe latter ſubſtances, however, it will be found that we have employed in the experiment about 2 pounds of water at 50°, 4 pounds of oil, and near 60 pounds of mercury, each of which has been heated 20°; ſo that it requires as much caloric to heat one pound of water 20° as to produce the ſame effect on two of oil, or thirty of mercury; and their *relative* capacities are therefore inverſely in this proportion.

Nor is it only among ſubſtances which eſſentially differ in their nature that this difference is found: the ſame body in different ſtates of exiſtence preſents us with equal varieties in its capacity. A change in this reſpect is producible in three ways: by mechanical compreſſion or dilatation, by chemical combination, or by the action of heat itſelf; of each of which we ſhall ſay a few words.

With regard to the firſt, the general fact appears to be, that wherever a body is by any means condenſed, its capacity becomes diminiſhed; but that where it is dilated or enlarged in its bulk, it is proportionally increaſed. Thus, if a thermometer be ſuſpended in a receiver, and a quantity of air condenſed into it, the mercury will riſe; a part of the caloric which is contained in the air being, as it were, ſqueezed out by its compreſſion, and forced into the mercury in the bulb, whoſe temperature is conſequently raiſed: if, however, on the contrary, the air be rarefied, the thermometer will indicate cold; the capacity of the air in the receiver being increaſed by its rarefaction, and a portion of the caloric in the contiguous bodies conſequently abſorbed, whereby their temperature is lowered and their bulk diminiſhed. It ſeems probable alſo that the heat produced by friction or percuſſion is, in like manner, to be referred to this kind of diminution in the capacity of the ſubject.

The ſecond mode of changing the capacities of bodies is by their chemical combination; and it is perhaps true, that there is no combination unaccompanied by ſuch a change. In ſome inſtances this takes place in a very remarkable degree, and it is from hence that we derive the effects of calorific and frigorific mixtures. If, for example, a quantity of ſulphuric acid, diluted with an equal meaſure of water, be poured on a quantity of cryſtals of Glauber's ſalt recently powdered, the capacity of the compound is conſiderably greater than that of its component ingredients, it becomes therefore ſtrongly abſorbent of caloric, which it attracts from the bodies in its vicinity, and a quantity of water in a phial placed in the mixture will be ſoon frozen. The converſe takes place in the combination of water and ſulphuric acid. The capacity of the compound becomes diminiſhed by the mutual attraction of the particles of its ingredients; a portion of the caloric which it contains is therefore extricated, and heat is produced by its emiſſion.

The third caſe of change of capacity, by the action of heat itſelf, is perhaps productive of more important effects in nature than either of the other two. The capacities of all bodies are increaſed in ſome proportion to the dilatation of their bulk, and the diſaggregation of their conſtituent particles as well by the agency of caloric as by any other cauſe. Hence, when a ſolid is fuſed, or a liquid reſolved into vapour, cold is produced by the augmentation of its capacity; and *e converſo*, when ſteam is condenſed, or congelation takes place, heat is developed by its diminution. Thus, if equal quantities of pounded ice and water, each at 32° of Fahrenheit, be expoſed to heat in two ſimilar veſſels in a water-bath, the water will be heated to 178° before the ice is all diſſolved, the water produced from which will of courſe ſtill remain at 32°, ſo that the increaſe of capacity in the ice, during its ſolution, is ſufficient to enable it to abſorb, without any elevation of its temperature, as much caloric as has raiſed the temperature of an equal quantity of water 146°; and the like quantity is alſo again emitted, on its becoming again congealed. If a quantity of water be expoſed without agitation to a degree of cold equal to 24° or 25°, it will frequently acquire this temperature without freezing; but as ſoon as congelation begins, the thermometer will immediately riſe to 32°, and the whole will remain at that temperature till all the water is converted into ice. From the quantity of heat which is abſorbed by ice during its ſolution, and the relative capacities of ice and water, which he conjectured from his experiments to be as 9 to 10, Dr. Crawford concludes that, as water on freezing appears to give out 146°, and this conſtitutes $\frac{1}{10}$ of all that it contains, it is probable that the temperature of a body which was entirely diveſted of heat would be 1460° below the freezing point, or 1428° below the zero of Fahrenheit's thermometer.

This latter change of capacity appears manifeſtly to be abſolutely eſſential to the well-being of the univerſe, as affording a conſtant modification of the action of heat and cold, whoſe effects would otherwiſe be inordinate. If this did not take place, the whole of a maſs of water which was expoſed to a temperature above the boiling point would be inſtantly diſſipated in vapour with exploſion. The fact, however, is, that the capacity of thoſe portions of the liquid which are ſucceſſively reſolved into vapour becomes thereby ſufficiently augmented to enable them to abſorb the ſuperabundant caloric, as faſt as it is communicated; and it is for this reaſon that boiling water in an open veſſel never reaches a higher temperature than 212°. The polar ices would all inſtantaneouſly diſſolve, whenever the temperature of the circumambient air was above 32°, if it were not that each particle abſorbs a quantity of caloric in its ſolution, and thereby generates a degree of cold which arreſts and regulates the progreſs of the thaw; and the converſe of this takes place in congelation, which is in its turn moderated by the heat developed in conſequence of the diminution of capacity, which takes place in the water during its tranſition to a ſolid ſtate.

CAPALITA, in *Geography*, a large town of North America, in the province of Guaxaca. The adjacent country abounds with ſheep, cattle, and excellent fruit.

CAPAN, in *Commerce*, an Eaſt Indian coin worth 3*d.* ſterling.

CAPANABASTIA, in *Geography*, a town of North America, in the province of Chiapa in Mexico; 70 miles S. E. of Chiapa des Eſpagnoles.

CAPARACOCH of Buffon, in *Ornithology*, the hawk-owl of Engliſh writers, *Strix Hudſonia* of Gmelin, and *Strix freti Hudſonis* of Briſſon.

CAPARASON, or CAPARISON, the covering or cloathing laid over an horſe; eſpecially a ſumpter, or horſe of ſtate.

The word is Spaniſh, being an augmentative of *cape*, *caput*, *head*.

Anciently the capariſons were a kind of iron armour, wherewith horſes were covered in battle.

CAPAS ISLANDS, in *Geography*, ſmall iſlands near the eaſt coaſt of Malacca, in the Eaſt Indies. N. lat. about 5°. E. long. 103° 30′.

CAPASH, a kind of head-dreſs worn by the women of Candia. It is of a ſtiffened fine muſlin, and is made ſo as to ſtand up very high, and extends out a great way on the right ſide. Pococke's Egypt, vol. ii. part ii. p. 10.

CAPA-VELA, in *Botany*. (Rheed. Mal.) See CLEOME PENTAPHYLLA.

CAPE ASTER. See CINERARIA AMELLOIDES.

CAPE JASMINE. See GARDENIA FLORIDA.

CAPE, in *Geography*, a head-land; or the extremity of a piece of land, or *promontory*, running out beyond the reſt, into the ſea.

Cape *of Good Hope*, a promontory of the ſouthern part of Africa, firſt diſcovered in 1487 by Bartholomew Diaz, a Portugueſe officer of diſtinguiſhed ſagacity, experience, and fortitude, and called by him, on account of the violence of the tempeſts with which he encountered, "Cabo Tormentoſo," or Stormy Cape; but his maſter, John II king of Portugal, entertaining no doubt of his having found the long deſired route to India, gave it a name of better omen, viz. "The Cape of Good Hope." Diaz merely deſcried this promontory; but the violence of the wind, the ſhattered condition of his ſhips, and the turbulent ſpirit of his ſailors, compelled him to return, after a voyage of ſixteen months. In 1497, Emanuel, king of Portugal, inheriting the enterpriſing genius of his predeceſſors, and perſiſting in their grand ſcheme of opening a paſſage to the Eaſt Indies by the Cape of Good Hope, equipped a ſquadron, conſiſting only of three veſſels, for this important voyage, and gave the command of it to Vaſco de Gama, a man of noble birth, and poſſeſſed of virtue, prudence, and courage, equal to the ſtation. Accordingly Gama ſet ſail from Liſbon on the 9th of July, and, after ſtruggling for four months with contrary winds, reached the Cape on the 20th of November. During an interval of calm weather he doubled that formidable promontory, which had ſo long been the boundary of navigation, and, after touching at ſeveral parts along the eaſtern African coaſt, terminated his voyage at Calicut on the coaſt of Malabar. See Calicut. Vaſco de Gama, however, made no attempt to form a ſettlement at the Cape. Next to Vaſco de Gama was the Portugueſe admiral Rio d'Infanté, who, in his voyage to India in 1498, went aſhore, and, on his return, ſtrongly recommended to his government the eſtabliſhment of a colony on the ſouthern continent of Africa; and he fixed upon the mouth of a river for that purpoſe, to which was given his own name, and which is now called the "Great Fiſh River." Some other attempts, by different Portugueſe navigators, were made to colonize the Cape, but they all failed. After this the Engliſh and Dutch frequently viſited the bays of the Cape. The Engliſh, in their outward-bound voyages, had a cuſtom of burying their diſpatches for the directors, and of pointing out where they were to be found, by cutting a ſentence to that effect on ſome large blue ſtone laid on a particular ſpot. The intelligence, engraven on the ſtone, was uſually limited to the name of the ſhip and captain, the date of her arrival and departure, and ended with, "Look for letters (in ſuch or ſuch direction) from this ſtone." Two or three ſtones of this kind are fixed in the caſtle-wall, and are ſtill legible. The Dutch uſed to bury, on a certain ſpot in Robben iſland, a regiſter of the ſtate of their veſſels and cargoes outward-bound, which the next ſhip, in coming home, took up and carried to Holland for the information of the directors. In this manner the Engliſh, the Dutch, and the Portugueſe, continued, for more than a century, to refreſh at the Cape, without any deſign on the part of the two former of appropriating the ſoil, until the year 1620, when the commanders of two fleets of Engliſh ſhips, bound for Surat and Bantam, took a formal poſſeſſion of the ſoil for, and in the name of, king James of Great Britain, becauſe they diſcovered that the Dutch intended to eſtabliſh a colony there in the following year. It was not, however, until a period of more than 30 years had expired after this event, that Van Riebeck, ſurgeon of a ſhip that put into the Cape for the uſual purpoſe, made repreſentations of the richneſs of the ſoil, the mildneſs of the climate, the advantages it would give to the Dutch, as a colony, over other nations, whoſe ſhips would all be obliged to touch there, and, above all, the barrier it would afford to their Indian dominions; which prevailed on the directors of the Dutch Eaſt India Company to form a regular eſtabliſhment at the Cape. Van Riebeck was appointed admiral of four ſhips properly equipped for ſuch an expedition, and, on his arrival at the Cape, governor in chief, with full power to eſtabliſh a ſettlement. He no ſooner propoſed than concluded a treaty; and the Dutch took immediate poſſeſſion of the Cape, which was ſurrendered to them by the natives with great ſolemnity. Van Riebeck erected a ſquare fort, containing lodgings, warehouſes, and an hoſpital for the ſick, and raiſed outworks and batteries to ſecure their ſettlements from all attacks. The original intention of the Dutch ſeems to have been to limit their poſſeſſions to the Cape peninſula, and the two bays that are divided by the iſthmus; conſidering it only, as it had hitherto been, a place for refreſhing and refitting their ſhips. But the number of ſettlers that joined them from time to time, in conſequence of the placard which they publiſhed for their encouragement, made it neceſſary to croſs the iſthmus, and, by preſents and promiſes, to obtain from the natives the ceſſion of a tract of land, to which they gave the name of "Hottentots' Holland." The natives had probably no idea of reſigning, for ever, to a foreign nation, the ground that was neceſſary for feeding their own cattle; but conceived it could only be intended for temporary uſe, and that, in time, they would depart from the country, as other Europeans had done for the laſt century and a half: but, when they obſerved them building houſes and fortifications, ſowing and planting the ground, and rearing their own cattle, they began to be jealous of the encroachments of their new neighbours, and commenced hoſtilities for the purpoſe of expelling them. Theſe hoſtilities terminated in the further extenſion of the Dutch ſettlement, and in an increaſe of troops and coloniſts from Europe. Still, however, the Dutch Eaſt India Company endeavoured to limit the Cape to the original deſign of a port for refreſhing their ſhips. They threw every obſtacle in the way of its becoming a flouriſhing ſettlement; allowed no trade whatſoever but that which paſſed through the hands of their own ſervants, and made it dependent on the governor-general of Batavia; concluding that the ſettlers would thus be made equally ſubmiſſive to their orders from Europe, and from the ſeat of their wealth and influence in the Eaſt. A colony, in ſuch a ſtate, with their declining commerce, entailed upon them a burden and expence too heavy for them to bear; and little doubt was entertained of their inclination to part with it for a moderate ſum of money, juſt before the French revolution and its deſtructive conſequences unſettled the affairs of all Europe. Overtures to this effect were intended to be made by England about the time when the above unfortunate event took place. It became wiſe and neceſſary, however, to recur to other meaſures for obtaining poſſeſſion of this Dutch colony. Accordingly, an expedition was ſent out for this purpoſe; which was commiſſioned not to act in an hoſtile manner, but to hold the Cape in defence and ſecurity for, and in the name of, the prince of Orange, who, having departed from Holland, furniſhed letters dated from London to this effect. Many of the coloniſts had, in the mean while, imbibed French principles, and became clamorous to declare themſelves, by ſome public act, a free and independent republic: they prepared to plant the tree of liberty, and eſtabliſhed a convention, whoſe firſt object was to make out proſcribed liſts of thoſe who were either to ſuffer death by the guillotine, or to be baniſhed out of the colony. The perſons ſo marked out to be the victims of an unruly rabble were ſelected from among the moſt worthy people in the ſettlement, and moſt of them were members of the government. The ſlaves, whoſe numbers of grown men are about five to one of male whites, had alſo their meetings to decide upon the fate of the free and independent burghers, when the happy days of their own emancipation ſhould arrive.

In this ſtate of things the Britiſh fleet appeared before the bay; and it became neceſſary to commence hoſtilities. The rocks of Muiſenberg were ſoon cleared by a few ſhot from a man of war, and the regular troops retreated to Wynberg, a tongue of land projecting from the eaſt ſide of the Table mountain, and about eight miles from Cape-town. The Britiſh troops, led on by general ſir James Craig, under the orders of ſir Alured Clarke, marched to attack the enemy on their elevated poſt, and aided by the ſailors, ſoon obliged them to retreat within their lines. A capitulation was propoſed and accepted, in September 1795; and the next day it was concluded between the two parties. By the 6th article of the treaty of peace at Amiens in March, 1802, it was ſtipulated, that the port of the Cape of Good Hope ſhould remain to the Batavian republic, in full ſovereignty, in the ſame manner as it did previous to the war; but that the ſhips of every kind belonging to the other contracting parties ſhould be allowed to enter the ſaid port, and to purchaſe neceſſary proviſions, without paying any other impoſt than ſuch as the Batavian republic demands the ſhips of its own nation to pay.

In order to form a juſt idea of the dimenſions of the Cape ſettlement, we may ſuppoſe a ſtraight line to be drawn from the ſouthern point of the Cape peninſula, which, however, is not the ſouthernmoſt point of Africa, in the direction of eaſt by north, and this line will interſect the mouth of the Great Fiſh river (the Rio d'Infanté of the Portugueſe), which is now conſidered as the eaſtern boundary of the colony. The length of this line is about 580 miles. Again, if from the ſame point a ſtraight line be drawn in the direction of north, with a little inclination weſterly, it will fall in with the mouth of the river "Kouſſie," the northern boundary of the colony, at the diſtance of about 315 miles. Moreover, if from the mouth of the Great Fiſh river, a line drawn in the direction of north-north-weſt, be continued to the diſtance of 225 miles, to a point behind the Snowy mountains called "Plettenberg's land-mark," and from thence be continued in a circular ſweep inwards to the mouth of the river "Kouſſie" upwards of 500 miles; theſe lines will circumſcribe the tract of country which conſtitutes the colony of the Cape of Good Hope. By reducing this irregular figure to a parallelogram, it will be found to comprehend an area of at leaſt 120,000 ſquare miles; and as the whole population of whites, blacks, and Hottentots, within this area, amounts only to about 60,000 perſons, every two ſquare miles may be ſaid to have at leaſt *one* human creature allotted to it. But as this deſert ſtate of the colony is leſs owing to the natural defects of the country, than to the regulations under which it has been governed, the population, compared with the extent of ſurface, ought not to be taken as the teſt of the intrinſic value of the ſettlement; ſince the population of any country, under a moderate climate, will, in the natural courſe of things, always riſe to a level with the means of ſubſiſtence. If we eſtimate the ſoil of the Cape by the abundance or ſcarcity, the luxuriance or poverty, of the native plants, independently of the clime, it would be pronounced one of the pooreſt in the known world; for ſeven parts in ten of the above-mentioned ſurface are, for a great part of the year, and ſome of them at all times, altogether deſtitute of verdure. The upper regions of all the chains of mountains are naked maſſes of ſand-ſtone; the valleys beneath them are clothed with graſs, with thickets, and in ſome caſes with impenetrable foreſts. The inferior hills or knolls, whoſe ſurfaces are generally compoſed of looſe fragments of ſand-ſtone, as well as the wide ſandy plains that connect them, are thinly ſtrewed over with heaths and other ſhrubby plants, exhibiting to the eye an uniform and dreary appearance. In the loweſt parts of theſe plains, where the waters ſubſide, and, filtering through the ſand, break out in ſprings upon the ſurface, vegetation is ſomewhat more luxuriant. In ſuch ſituations the farm-houſes are generally placed; and the patches of cultivated ground contiguous to them, like the “Oaſés” in the ſandy deſerts, may be conſidered as ſo many verdant iſlands in the midſt of a boundleſs waſte. Of ſuch plains and knolls is the belt of land compoſed, that lies between the firſt chain of mountains and the ſea-coaſts. Soils, in this tract of country, are generally either a ſtiff-clay, impenetrable by the plough till they are ſoaked by much rain, or light and ſandy, tinged with red and abounding with ſmall round quartoze pebbles. A black vegetable mould ſeldom appears except in patches of garden-ground, vineyards, and orchards that ſurround the habitations, where, by long culture, manure, and the fertilizing influence of ſprings or rills of water, the ſoil is ſo far mellowed as to admit the ſpade at all ſeaſons of the year. The extenſive plains, known in the colony by the Hottentot name of “Karroo,” which are interſperſed between the great chains of mountains, exhibit a more diſmal appearance than the lower plains, which are chequered with patches of cultivated ground; and their hard ſurfaces of clay, gliſtering with ſmall cryſtals of quartz, and condemned to perpetual drought and aridity, are ill adapted to vegetation. The hills that break theſe barren plains, are chiefly compoſed of fragments of blue ſlate, or maſſes of feltſpar, and argillaceous limeſtone. However, in thoſe Karroo plains, that are tinged with iron, and that are capable of being watered, the ſoil is extremely productive. In ſuch ſituations, more eſpecially in the vicinity of the cape, they have the beſt grapes, and the beſt fruit of every ſort. The climate of the Cape is not unfriendly to vegetation; but it is ſo ſituated, within the influence of periodical winds, that the rains are very unequal, deſcending in torrents during the cold ſeaſon, though hardly a ſhower falls to refreſh the earth in the hot ſummer months, when the dry ſouth-eaſt winds prevail. Theſe winds blaſt the foliage, bloſſom, and fruit of all thoſe trees that are not well ſheltered; nor is the human conſtitution ſecure againſt their injurious influence. They relax both the body and mind, and deaden their powers of energy and activity. As a protection from theſe winds, the coloniſts who inhabit the nearer ſide of the firſt chain of mountains, beyond which their effect does not very ſenſibly extend, divide that portion of their ground, which is appropriated to fruit groves, vineyards, and gardens, by oak ſcreens; but they leave their corn lands altogether open. Indeed, a cape boor beſtows no more labour on his farm than is abſolutely neceſſary; and as grain is moſtly reaped before the ſouth eaſt winds are ſet in, the encloſure of the arable land is omitted. The temperature of the climate at the Cape is remarkably affected by local circumſtances. During the winter months, May, June, and July, the mean temperature, according to the ſtatement of Kirwan (Eſtimate, &c. p. 102), ſeems to be from 45° to 55°; the heat ſcarcely exceeds 64°, and ſeldom falls ſo low as 34°; in ſummer the thermometer is generally between 70° and 80°, and ſometimes between 80° and 90°, but ſcarcely ever exceeds 95°; the ſouth-eaſt wind, he adds, is the coldeſt. Mr. Barrow informs us (*ubi infra*), that there is a difference of at leaſt from 6 to 10 degrees of Fahrenheit, in the ſummer months, between Cape Town and Wynberg, within a diſtance of only about 7 or 8 miles; which ariſes from the latter place being ſituated on the windward ſide of the Table mountain, and the former lying to leeward of it. The variation of climate, to which the Table valley is ſubject, led a Britiſh officer to obſerve, that thoſe who inhabited it were either in an oven, or at the funnel of a pair of bellows, or under a water-ſpout. On the Cape ſide of the mountains the thermometer rarely deſcends below 40°; but on the elevated Karroo plains, within the mountains, it is generally, in the winter months, below the freezing point by night, and from 70 to 80 in the middle of the day. In order to account for the intenſe cold of the Karroo plains, Van Humboldt adduces the chemical decompoſition of the atmoſpherical air. As fat and clayey earths are ſtrongly diſpoſed to attract the oxygen from the atmoſphere, by which the azotic gas is let looſe: this gas entering again into combination with freſh oxygen, of the ſuperincumbent ſtratum, in an increaſed proportion, forms nitric acid, from which ſalt petre is generated. The conſequence of this formation which actually takes place in thoſe plains, muſt neceſſarily be a great diminution of temperature.

We may now proceed to obſerve, that the great ſcarcity of water in ſummer is much more unfavourable to an extended cultivation than either the ſoil or the climate. The torrents of rain that deſcend for about four months in the year, deluging the whole country, diſappear ſuddenly in the deep channels that interſect the country, and in conſequence of their ruſhing with rapidity and violence into the ſea, and leaving the deeply ſunken beds of the rivers nearly dry, afford no ſufficient ſupply of water to anſwer the purpoſes of irrigation. The periodical rivulets, and the ſtreams that iſſue from the mountain ſprings, are either abſorbed or evaporated before they arrive at any great diſtance from their ſources; ſo that in this extenſive colony one can ſcarcely ſay that there is a ſingle navigable river. The two principal rivers, on the weſtern coaſt, are the “Berg,” or Mountain river, which riſes in the mountains that encloſe the vale of Drakenſtein, and falls into St. Helena bay, and the “Oliphant,” or Elephant's river, which, after collecting the ſtreamlets of the firſt chain of mountains in its northerly courſe along their feet, empties itſelf into the Southern Atlantic in S. lat. 31° 30′. Although both theſe rivers have permanent ſtreams of water, ſufficiently deep to be navigable by ſmall craft to the diſtance of about 20 miles up the country, yet the mouth of the former is choaked up with a bed of ſand; and acroſs the latter is a reef of rocks. On the ſouth coaſt of the colony the permanent rivers of any magnitude are the “Broad” river, which is diſcharged into St. Sebaſtian's bay, croſſed near its mouth by a bar of ſand, but navigable within this bar by ſmall craft about 30 miles up the country, in which extent there are ſcarcely half a dozen farm-houſes; the “Gauritz” river; the “Knyſna;” the “Keurboom;” the “Camtoos;” the “Zwartkops;” the “Sunday;” and the “Great Fiſh” rivers; which ſee reſpectively. All theſe rivers are well ſtocked with perch, eels, and ſmall turtle, and, to a certain diſtance from the ſea-coaſt, they abound with almoſt every kind of ſea-fiſh peculiar to this part of the world. Beſide theſe rivers, the whole ſlip of land, ſtretching along the ſea-coaſt, between the entrance of Falſe bay and the Great Fiſh river, is interſected by ſtreamlets, whoſe waters are neither abſorbed nor evaporated; but they generally run in ſuch deep chaſms, that they are of little uſe towards the promotion of agriculture by the aid of irrigation. In order to account for theſe deep chaſms or cavities, and the general ſcarcity of ſprings, notwithſtanding the quantity of rain that annually falls at the Cape, Mr. Barrow ſuggeſts the following conſiderations. All the continued chains of mountains in Southern Africa are compoſed of ſandſtone, reſting upon a baſe of granite. The granite baſe is ſometimes elevated conſiderably above the general ſurface of the country, and ſometimes its upper part is ſunk as far beneath it. In ſituations where the former circumſtance occurs, numerous ſprings are found, as in the Table mountain, where, on every ſide, copious ſtreams of pure limpid water, filtered through the immenſe maſs of ſuperincumbent ſandſtone, glide over the impenetrable ſurface of granite, and furniſh an ample ſupply to the whole town, the gardens, and the adjacent farms. But in thoſe places where the ſandſtone continues to deſcend below the ſurface, and the upper part of the granite baſe is ſunk beneath the general level of the country, the ſprings that make their appearance are few and ſcanty. From theſe facts it is inferred, that the ciſterns or cavities in the ſand-ſtone mountains, being corroded in the lapſe of ages, to a greater depth than the openings or conduits, which might, perhaps, at one time have given their waters vent, the ſprings can no longer find their way upon the ſurface, but oozing imperceptibly between the granite and the ſand-ſtone, below the general level of the country, glide in ſubterraneous ſtreams to the ſea. It is a well known fact, that on almoſt every part of the iſthmus that connects the mountainous peninſula of the Cape to the continent, freſh water may be procured at the depth of 10 or 12 feet below the ſandy ſurface. Other facts of a ſimilar nature ſerve to evince the erroneouſneſs of the opinion, that has generally prevailed, that the ſeveral bays of the colony cannot, without great difficulty, if at all, be ſupplied with freſh water. This great depth of the commencement of the granite baſe below the ſurface may alſo better account for the moſt conſiderable rivers of Africa loſing themſelves in the ſand, before they reach the ſea, than by ſuppoſing the interior parts of this continent to be lower than the level of the ocean.

Another circumſtance that has very much contributed to retard the cultivation of the territories adjoining to the Cape, is the extreme indolence of the coloniſts. In this fine climate they engage in little or no manual labour. The extent of the foreſts, beginning at Moſſel bay, and running eaſtward parallel to the ſea-coaſt, is at leaſt 250 Engliſh miles, and the breadth from the baſe of the mountains to the ſea is 10, 15, and in ſome places, 20 miles. Of this tract a great part is compoſed of large and beautiful plains, interſected by numerous rivers, and abounding in lakes full of excellent fiſh. The ground is well adapted either to paſturage or tillage, and capable of complete irrigation; but the farmers here, as well as in all other parts of the colony, are lazy beyond deſcription; the grounds held by each being ſufficient for a great number of induſtrious families. It has been ſaid, that the ſlip of land between the firſt chain of mountains and the ſea-coaſt, and from Zwellendam to Algoa bay, if well ſtocked with inhabitants, ſo that each would be under a neceſſity of labouring for a ſubſiſtence, would not only be able to furniſh a ſupply of grain for the whole colony, but afford alſo a ſurplus for exportation. But though this opinion may not be ſtrictly juſt, yet Mr. Barrow is confident, that, with the addition of the tract of country between the north range of mountains and the weſt coaſt, and from St. Helena bay to the Cape, the whole maſs of people within the preſent limits of the colony might be more comfortably ſubſiſted than they now are, and have an abundance of corn, cattle, wine, and other neceſſaries, over and above, for a garriſon of 5000 men, and for a fleet containing an equal number. But in order to make the country produce this ſupply, it will be neceſſary to procure a new race of inhabitants, or to change the nature of the old ones.

It is impoſſible, ſays this ingenious writer, to convey, by any deſcription, an adequate idea of the condition of the peaſantry of the Cape of Good Hope; as it is ſo inconceivably different from that of the ſame claſs in Europe, or indeed in any other part of the world. In the miſerable hovels of the Cape boors ſalted beef, or fleſh of the larger kinds of game, will be found hanging in the chimney, and the whole or greater part of a ſlaughtered ſheep may be ſeen ſuſpended from the roof. A Cape boor never works. His greateſt and moſt pleaſing exertion is the killing of game. But in this kind of exerciſe he manifeſts no energy or activity, and ſubmits to no fatigue. A Dutch boor never traverſes the heath on foot, but generally fires from the ſaddle; and even avoiding the fatigue of carrying his muſket, he is followed by a Hottentot boy, trained to ride or run after him as his armour-bearer. It is a miſtaken notion, that the peaſantry of the Cape are a poor and diſtreſſed people, overwhelmed with debt, burdened with taxes, and oppreſſed by the government in a variety of ways. This will ſufficiently appear in the ſequel of this article. But they are better fed, more indolent, more ignorant, and more brutal than any ſet of men, bearing the reputation of being civilized, upon the face of the whole globe. Inſtances frequently occur of their ſavage and inhuman treatment of the HOTTENTOTS, whom they retain in a ſtate of connection and dependance, by violence and oppreſſion on one ſide, and by want of energy and patient ſuffering on the other. This ſanguinary character of many of the African coloniſts may, perhaps, be owing, in a certain degree, to the circumſtance of their having been ſoldiers in German regiments ſerving abroad; where the leaſt relaxation from a rigid ſyſtem of diſcipline is followed up by the greateſt ſeverity of puniſhment. People of this deſcription, having riſen into affluence by the general proſperity that followed the conqueſt of the ſettlement, and indulging indolent habits and luxurious living, become no leſs groſs in their perſons than vulgar in their manners. Whilſt they pay little attention to domeſtic and ſocial intercourſe, and are in a very culpable degree regardleſs of character, they are extremely tenacious of their rank. There are, however, many perſons in the colony to whom theſe obſervations are not applicable; men, whoſe talents and information, propriety of conduct, and ſtrict integrity, would command reſpect in any part of the world: but their number is not very conſiderable. The Malay ſlaves, in the ſervice of the Dutch, are unaccountably preferred to the Hottentots; though they are generally much inferior to the latter in talents, and much more capricious, cruel, and revengeful. The proportion of ſlaves to whites, of both ſexes and all ages, in the Cape town, is not more than two to one; but that of ſlave men to white men is near five to one. The field ſlaves belonging to the farmers are not, however, nearly ſo well treated as thoſe of the town; yet infinitely better than the Hottentots who are in their employ; the farmer, indeed, having a life-intereſt in the one, and only 25 years in the other, is a circumſtance that may explain the difference of treatment. The one, alſo, is convertible property, which is not the caſe with reſpect to the other. The country ſlaves, notwithſtanding, are ill fed, ill cloathed, work extremely hard, and are frequently puniſhed with great ſeverity ; ſometimes with death, when rage overpowers the dictates of prudence and the feelings of compaſſion.

Mr. Barrow, in the 2d volume of his "Travels in Southern Africa," has ſtated and examined, very much in detail, the advantages which the Cape of Good Hope poſſeſſes, as a military ſtation ; as a port and naval ſtation ; and as a commercial emporium and territorial acquiſition. By a military ſtation Mr. Barrow means, not only a garriſon for the defence of the ſettlement, but likewiſe a depôt, or place ſuitable for collecting and forming, ſo as always to have in readineſs, a body of troops, either belonging to his majeſty's regular regiments, or to the armies of the Eaſt India company, fitted and prepared for foreign ſervice, and ſeaſoned for the climate either of the Eaſt or Weſt Indies. This ingenious writer is of opinion, that the Cape of Good Hope eminently points out ſuch a ſtation. Its geographical poſition on the globe is ſuch as evidently to recommend it for this purpoſe. Its diſtance from the coaſt of Brazil is the voyage of a month ; from the Dutch colonies of Surinam, Demarara, Berbice, and Eſſiquebo, with the Weſt India iſlands, ſix weeks ; the ſame to the Red Sea ; and two months to the coaſts of Malabar and Coromandel. With the eaſt and the weſt coaſts of Africa and the adjacent iſlands, it commands, at all ſeaſons of the year, a ready communication. It is ſo ſituated, juſt half way between England and India, in a temperate and wholeſome climate, and productive of refreſhments of every deſcription, as to poſſeſs peculiar and very diſtinguiſhing advantages for a ſtation and depôt, that would admirably ſuit the views and occaſions of the Eaſt India company in particular. To England the Cape is more valuable as a point of effectual ſecurity to her Indian trade and ſettlements, than as a place of annoyance to other nations, or as to the means it affords of interrupting their commercial concerns. Conſidered as a naval ſtation, the Cape would ſecure us a port for refreſhing and refitting the ſhips of the Eaſt India company ; as a ſtation for ſhips of war commanding the entrance into the Indian ſeas ; and as affording, by its geographical poſition, a ready communication with every part of the globe. Again, the Cape, conſidered in a commercial point of view, might be rendered extremely advantageous to the intereſts of the Britiſh empire, as an emporium of Eaſtern produce ; as furniſhing articles of export for conſumption in Europe and the Weſt Indies ; as taking, in exchange, for colonial produce, articles of Britiſh growth and manufacture ; and as a central depôt for the ſouthern whale-fiſhery. The chief articles of colonial growth and produce conſumed upon the ſpot, and exported to the Eaſt Indies, Europe, and America, may be compriſed under the heads of grain and pulſe, wine and brandy, wool, hides and ſkins, whale oil and bone, dried fruits, ſalt proviſions, ſoap and candles, aloes, ivory, and tobacco. The wheat produced at the Cape is ſaid to be as good and heavy as that of moſt other parts of the world. A load of this grain conſiſts of ten "muids," or ſacks, equal to 31 Wincheſter buſhels ; and a "muid," or $3\frac{1}{10}$ Wincheſter buſhels, uſually weighs 180 Dutch pounds; which are equal to $191\frac{1}{4}$ pounds Engliſh. The returns are from 10 to 70, according to the nature of the ſoil, and the ſupply of water. Barley, i. e. beer or big, is a productive grain at the Cape, and is only uſed for feeding horſes. Rye is alſo a thriving grain, and is little uſed except for cattle in a green ſtate, and oats, which run much into ſtraw, and are fit only for horſes as green fodder. Peas, beans, and kidney beans, Indian corn or maize, and various kinds of millet, may be ſupplied to any amount. However, the Cape, in its preſent ſtate, is not capable of exporting any grain. Wine and brandy may be conſidered as the ſtaple commodities of the Cape of Good Hope. Ten or twelve different kinds of wine are manufactured at the Cape, having a diſtinct flavour and quality according to the farms on which they are produced. The beſt bodied wine that is made at the Cape, is the Madeira, ſent to Holland and the Dutch ſettlements in India, taken by the Americans in exchange for ſlaves, and purchaſed by Engliſh merchants. See CONSTANTIA.

The country boor ſells his new wine to the merchants in the town, where it is adulterated in a variety of ways. The pipe is called a "legger," and contains 8 half aums or 160 gallons ; each legger paying to government a duty, on entering the town, of 3 rix-dollars. The farmer generally receives from 20 to 30 rix-dollars per legger, which, after adulteration, is ſold from 40 to 60, and frequently at the rate of 80 to 100 rix-dollars. Brandy might become a very important commodity as an article of export ; but the cultivators of the vine have at preſent no proper diſtillatory apparatus, nor ſufficient knowledge properly to conduct thoſe which they have. It is exported at 80 to 160 rix-dollars per legger, and ſubject to the ſame toll, on entering the town, as wines : and both wine and brandy are liable to a further duty of 5 rix-dollars per legger on exportation. The whole export value of wines, including the Conſtantia, and the brandy, may amount, one year with another, to about 50,000 rix-dollars, or 10,000l. currency. Wool, which has till a late period been neglected, is likely to become a ſource of colonial revenue. It is ſaid to have been ſold, in its rough ſtate, in the London market at 3s. to 3s. 6d. the pound. It admits of great improvement. The mutton of the Cape ſheep is coarſe and deſtitute of flavour. Hides and ſkins, both dried and ſalted raw, are an increaſing article of exportation. The quantity of ox-hides exported may amount to between 2000 and 3000 annually, ſubject to a duty of $3\frac{1}{2}$d. a piece. Thoſe taken off cattle, killed in the country, are uſed as harneſs for their waggons, and thongs to ſupply the place of cordage. The ſkins of ſheep, killed in the country, are converted into ſacks, and employed as clothing for the ſlaves and Hottentots. Few are exported. The ſkins of the wild antelopes and leopard, though brought occaſionally to the Cape market, hardly deſerve mention as articles of export. The caſe is the ſame with regard to oſtrich feathers ; the annual amount of which is very trifling. The whole value of one year's exportation of this article does not exceed 1000 rix-dollars ; of hides and ſkins of every deſcription not more than 5000 or 6000 rix-dollars. All the whales which have been caught in the bays of the Cape are females of a ſmall ſize, and yielding from 6 to 10 tons of oil each. The bone is ſmall, and, on that account, of no great value. Under the head of dried fruits, the moſt important articles are almonds and raiſins. The cultivation of vines admits of great improvement ; better grapes are not produced in any part of the world than thoſe at the Cape of Good Hope : but neither their wines nor raiſins are properly managed. The almonds are, in general, very ſmall, but of good quality ; and as the trees thrive well in the drieſt and worſt ſoils, the quantity of theſe nuts might be produced to an indefinite amount. Before the capture almonds ſold from 1s. to 1s. 6d. ſterling the thouſand, and raiſins from 2d. to 3d. a pound ; but their price has ſince conſiderably advanced. Dried peaches, apricots, pears, and apples, are not only plentiful, but good of their kind. The whole value of dried fruit, ſhipped in the year 1802, amounted only to 2542 rix-dollars, ſubject to a duty on exportation of 5 per cent. Salt proviſions are ſuſceptible of great improvement, by curing them at Algoa bay, and bringing them down in ſmall coaſting veſſels to the Cape. Salt is ſpontaneouſly produced

Strahan and Preſton

within a ſew miles of Cape-town, by the evaporation of water in the ſalt lakes that abound along the weſt coaſt of the colony. Two kinds of fiſh, the "Hottentot" and the "Snook," are ſalted and dried in the ſun in large quantities, for the uſe of the agricultural ſlaves, who eat them by way correcting the bilious effects of bullocks' livers and other offal, that conſtitute a great part of their food. Salt-butter is a very material article for the conſumption of the town, the garriſon, and the navy, and alſo for exportation. That which comes from the Snowy mountains is accounted the beſt; but very little of it is good. Soap is manufactured by almoſt every farmer in the country, and furniſhes in ſome parts the means of procuring cloaths and other neceſſaries at their annual viſit to Cape-town. The unctuous part is chiefly derived from the fat of ſheeps' tails, and the potaſh or barilla is the lixiviated aſhes procured from a ſpecies of ſalſola called "canna," that grows abundantly on thoſe parts of the Karroo, or deſerts, that are interſected by periodical ſtreams of water. Candles are ſeldom brought out of the country; but a vegetable wax, collected from the berries of a ſhrubby plant, the "myrica cerifera," plentiful on the dry marſhy grounds near the ſea-ſhore, is ſometimes ſent up to the Cape in large green cakes, and ſold from 1s. to 1s. 3d. a pound. The tallow purchaſed at the Cape is hardly ſufficient for the conſumption of the town and garriſon, and the candles made from it are ſeldom lower than 1s. 3d. a pound. The aloe perfoliata, or ſuccotrina, is produced in large tracts of ground, many miles in extent, which are covered with ſpontaneous plantations of it; and eſpecially in the diſtrict of Zwellendam, not far from Moſſel-bay. A load of aloes at Cape-town is worth from 18l. to 20l. The total amount of this article, entered on the cuſtom-houſe books, in the courſe of 4 years from 1799 to 1802, was 341,927 lbs., value 25,665 rix-dollars. It is ſubject to an exportation duty of 16d. for every 100 pounds. Ivory is now become ſcarce, few elephants being found within the limits of the colony. The whole quantity exported in the courſe of 4 years amounted only to 5981 pounds, value 6340 rix-dollars. The hippopotamus, or ſea-cow, whoſe teeth furniſhed the beſt ivory, is no longer within the limits of the colony. The colony is capable of producing great quantities of tobacco; however, very little is exported, though the Cape tobacco is ſaid to be as good, when duly prepared, as that of Virginia. As all male perſons, old and young, ſmoke in the Cape, and as American tobacco generally bears a high price, the conſumption of that of native growth is conſiderable. The inferior ſort is uſed by ſlaves and Hottentots. The total value of every kind of colonial produce, exported in 4 years, from 1799 to 1802, amounts to 300,925 rix-dollars, or 60,185l. currency. From the above detail it appears, that the Cape of Good Hope is, in its preſent condition, of very little importance to any nation; conſidered with regard to its articles of exportation.

The goods imported from England into the Cape, in 4 years, from 1799 to 1802, conſiſted of woollen cloths, Mancheſter goods, hoſiery, haberdaſhery, and millinery, boots, ſhoes, and hats, cutlery, iron tools, ſtationary, bar and hoop iron, ſmiths' coals, houſehold furniture, paint and oils, earthen ware, naval ſtores, tongues, hams, cheeſe, and pickles; and from India and China were imported Bengal, Madras, and Surat piece-goods, tea, coffee, ſugar, pepper, ſpices, and rice. The Americans brought thither lumber, cargoes of deal plank, ſtaves, balk, ſalt-fiſh, pitch, turpentine, &c.; and the Danes, Swedes, and Hamburgh ſhips aſſorted cargoes of iron, plank, French wines, beer, gin, Seltzer water, coffee, preſerves, pickles, &c. in exchange for refreſhments, to defray the charges of repairs and other neceſſaries, or for hard money to carry to India or China. The whole importation into the Cape by Britiſh or foreign bottoms, from Europe, Aſia, and America, in 4 years, including the value of the prize goods brought in, and of the ſlaves imported within the ſame period, amounted to 5,977,535 rix-dollars 7 ſk. or 1,195,507l. 3s. 6d. currency.

When the Dutch Eaſt India company perceived their ſettlement extending far beyond the bounds which they had originally preſcribed, they found it expedient to divide the country into diſtricts, and to place over each a civil magiſtrate with the title of "Landroſt," who, with his council called "Hemraaden," was authoriſed to ſettle petty diſputes among the farmers, or between them and the native Hottentots, levy fines within a certain ſum, collect and apply the parochial aſſeſſments, and enforce the orders and regulations of government. His diſtrict was divided into a number of ſubdiviſions, over each of which was appointed a "Feldtwagtmeeſter" or country overſeer, whoſe duty was to take cognizance of any abuſes committed within his diviſion, and report the ſame to the landroſt, to adjuſt diſputes about ſprings, or water-courſes, and to forward the orders of government. The landroſt, however, had only the ſhadow of authority. The council and the country overſeers were compoſed of farmers, and were always more ready to ſkreen and protect their brother boors, accuſed of crimes, than to aſſiſt in bringing them to juſtice. The poor Hottentot had, therefore, little chance of obtaining redreſs for the wrongs he ſuffered from the boors. If he eſpouſed their cauſe, he became unpopular; and the diſtance from the capital was a ſufficient obſtacle to the preferring of complaints before the court of juſtice at the Cape, which itſelf had little influence in enforcing its orders in a part of the country diſtant 5 or 600 miles. Hence it happened that murders and the moſt atrocious crimes were committed with impunity; and the only puniſhment was a ſentence of outlawry for contempt of court, when the criminal did not appear to his ſummons, which ſentence was little regarded. This extenſive ſettlement is divided into 4 diſtricts; thoſe of the Cape, of Stellenboſch and Drakenſtein, of Zwellendam, and of Graaf Reynet, which ſee reſpectively.

When the Dutch government obtained, partly by purchaſe and partly by force, a tract of country from the Hottentots, it made grants of land to the ſettlers on four different tenures. The moſt ancient of theſe is that of "loan" lands; which were grants made to the original ſettlers of certain portions of land to be held on yearly leaſes, on condition of paying to government an annual rent of 24 rix-dollars. Every farm was to conſiſt of the ſame quantity, and to be ſubject to the ſame rent, without any regard to the quality of the land. This tenure amounted by renewals of the leaſe, at firſt made only for one year, to a leaſehold in perpetuity. The number of theſe loan-farms in the four diſtricts amounted in 1798 to 1832: and ſuppoſing each farm to conſiſt only of the uſual allowance, or a ſquare of 3 miles the ſide, the quantity of land in all theſe farms would amount to 10,552,320 acres, and the annual rent they produce is about 44,000 rix-dollars, or about $\frac{8}{10}$ths of a farthing per acre. The ſecond tenure was that of "gratuity" lands, which were originally granted in loan; but, on petition of the holders, in conſequence of ſome ſuppoſed ſervices done to government, they have been converted into a ſort of cuſtomary copy-hold liable to a certain rent, which, like the loan lands, is continued at 24 rix-dollars a year: the number of theſe eſtates is 107. The third tenure is that of "quit-rents," ariſing from pieces of waſte-ground, which, being contiguous or convenient to an eſtate, have been allowed by government to be occupied by the owners of ſuch eſtates upon a leaſe of 15 years, on condition of their paying an annual rent of one ſhilling per acre. The renewal on this payment is a matter of courſe.

Of ſuch grants there are 35. The fourth tenure is that of "real eſtates" held in fee-ſimple, and ſubject to no rent; and they are chiefly ſituated in the Cape diſtrict or its vicinity. Theſe are the choiceſt patches of land, and have been originally ſold or granted to the early ſettlers in parcels of about 60 morgen, or 120 Engliſh acres.

The 22,000 chriſtian inhabitants that compoſe the population of this colony may be diſtributed into four claſſes; viz. the people of the town, (See Cape *Town*), wine-growers, grain-farmers, and graziers. The wine-growers, or wine boors, occupy the beſt houſes and the moſt valuable eſtates; and are deſcendants of the French families who firſt introduced the vine. Theſe eſtates are moſtly freehold, in extent about 120 Engliſh acres, and moſtly employed in vineyards and garden-grounds. They bring their wine to market from September to the new vintage in March; and the deep ſandy roads over the Cape iſthmus require 14 or 16 oxen to draw 2 leggers of wine, whoſe weight is not 2½ tons. The wine brought to market is ſubject to a tax of 3 rix-dollars for every legger, and the brandy, paſſing the barrier, pays the ſame ſum. The wine or brandy, conſumed at home, or ſold in the country, is free of duty: nor are they ſubject to any parochial taxes or aſſeſſments, a ſmall capitation tax excepted. Theſe wine-farmers make their excurſions in their tent-waggons drawn by ſix or eight horſes. The corn-boors live chiefly in the Cape diſtrict and thoſe parts of Stellenboſch and Drakenſtein that are not more than two or three days' journey from the Cape; and are next in rank to the wine-boors. The grain, which they ſell in the country, is ſubject to no tax or tithe: but a duty, about one tenth of the value, is paid at the barrier for all grain paſſing towards Cape-Town. Their parochial aſſeſſments are the ſame as thoſe of the wine-boor. The coloniſts of the Cape are very bad agriculturiſts, and owe their crops more to the goodneſs of the ſoil and favourable climate than to their own ſkill or induſtry. Their plough is an unwieldy machine drawn by 14 or 16 oxen, which juſt ſkims the ſurface and does not penetrate the ſtiff ſoil. Such grounds, when ſown and harrowed, are infinitely more rough than the roughest lea-ploughing in England. They rarely give themſelves the trouble of manuring, except for barley. For returns of corn they generally reckon upon fifteen-fold, in choice places from 20 to 30, and more where they have the command of water. The grain is not threſhed, but trodden out in circular floors by cattle. The annual balance in favour of the farmer is about 143l. 13s. The graziers are thoſe of Graaf Reynet, and other diſtant parts of the colony. They are the leaſt advanced in civilization. The hovels in which they reſide have ſeldom more than two apartments, and frequently only one, in which the parents with ſix or eight children and the houſe Hottentots all ſleep. Their bedding conſiſts of ſkins. The walls of their hovels are formed of mud or clay baked in the ſun; they are ſometimes conſtructed with ſods and poles; and frequently a ſort of wattling plaiſtered over with a mixture of earth and cow-dung, both within and without; and they are rudely covered with a thatch of reeds, ſeldom water-proof. As to their clothing, the men generally wear a broad-brimmed hat, a blue ſhirt, and leather pantaloons, no ſtockings, but a pair of dried ſkin ſhoes. The women have a thick quilted cap that ties with two broad flaps under the chin, and falls behind acroſs the ſhoulders; a ſhort jacket and a petticoat, no ſtockings, and frequently they uſe no ſhoes. The bed for the maſter and miſtreſs of the family is an oblong frame of wood, ſupported on four feet, and reticulated with thongs of a bullock's hide, ſo as to ſupport a kind of mattreſs made of ſkins ſewed together, and ſometimes ſtuffed with wool. In winter they uſe woollen blankets. The bottoms of their chairs or ſtools are net-work of leather thongs. A large iron pot ſerves both to boil and broil their meat. They have neither linen for the table, nor knives, forks, or ſpoons. The boor carves with a large knife, which he carries in his pocket, for the reſt of the family. Their huts and their perſons are equally dirty, and their whole appearance betrays an indolence of body, and a low groveling mind. The women are greater drudges than the men, and yet they are not very induſtrious. Thongs cut from ſkins ſerve, on all occaſions, in lieu of ropes, and fibres cut from the tendons of wild animals are a ſubſtitute for thread. The folds or "kraals" in which they houſe their cattle at nights immediately front the doors of their huts; and as they are never cleaned out, they increaſe the filthineſs of their dwellings. Few of the diſtant boors have more than one ſlave, and many of them none; but the number of Hottentots, on an average, in Graaf Reynet, amounts to 13 to each family; and they are uſed with the moſt inexcuſable inhumanity. The produce of the graziers is ſubject to no kind of colonial tax. They pay only a ſmall parochial aſſeſſment proportioned to their ſtock; for every 100 ſheep a florin, or 16d., and for every ox or cow 1d. The condition of the farmers is ſuch, that each of them, upon a balance of his income and outgoings, ſaves annually 93l. 16s.

The revenues of the colony are derived from the following ſources; viz. land revenue ariſing from rents (already explained); places for grazing cattle taken by the month, and ſalt-pans; duties on grain, wine, and ſpirits, levied at the barrier; transfer duty on ſale of immoveable eſtates; duty ariſing from the ſale of buildings on loan farms; public vendue duty; fees received in the ſecretary's office on regiſtering the transfer of property; cuſtoms; port fees; poſtage of letters; ſeizures, fines, and penalties; licences to retail wine, beer, and ſpirituous liquors; intereſt of the capital lent out through the loan-bank; and duty ariſing from ſtamped paper. The whole amount of this revenue in 1801 was 90,142l. 13s. 4d. This revenue is applied to the payment of ſalaries on the civil eſtabliſhment, the expences of the ſeveral departments, the repairs of government buildings, and the contingencies and extraordinaries of the colony; and during the government of lord Macartney, when the Cape was in the poſſeſſion of this country, the revenue was more than adequate to the expenditure.

The members of the court of juſtice at the Cape are choſen out of the burghers of the town. The fiſcal, who is the public accuſer in criminal matters, and the ſecretary of the court, are the only perſons poſſeſſed of legal knowledge. The litigious ſpirit of the people, encouraged by the attornies who enter into the profeſſion without any knowledge of the law, multiplies cauſes; and the expences of a ſingle ſuit will ſometimes amount to 400 or 500l. ſterling, though the object of litigation was not worth 100l. The office of fiſcal, one of the moſt important in the colony, conſiſted of the principal and a deputy, a clerk, two bailiffs, two jailors, eight conſtables, and 19 blacks and Malays, uſually called "Kaffers." The whole expence to government was under 10,000 rix-dollars; the court of juſtice and ſecretary's office amounted to about the ſame ſum; ſo that the adminiſtration of juſtice coſt the government about 4000l. ſterling a year. The court of commiſſaries for trying petty ſuits (not exceeding 40l.) and for matrimonial affairs (or granting licences) conſiſts of a preſident, vice-preſident, and four members, whoſe ſituations are honorary and biennial. The "Weeſkammer," or chamber for managing the effects of minors and orphans is one of the original inſtitutions of the colony, and it is managed by a preſident and four members, a ſecretary and ſeveral clerks. For the ſupport of this inſtitution all orphan property, paſſing through the chamber, ſuffers a reduction of 7½ per cent. upon the capital.

The eſtabliſhed religion of the colony is Calviniſm, or the reformed church. Other ſects are tolerated; the Lutherans have a church; a methodiſt chapel has been lately built; the Moravians have a church; but the Malay Mahometans, being refuſed a church, perform their public ſervice in the ſtone-quarries at the head of the Cape town. The clergy are ſuitably provided for and generally reſpected in this country; and they rank next to the preſident of the court of juſtice in town, and the landroſt in the country. Beſides their clerical duties, they have alſo the direction of the funds for the relief of the poor; which are raiſed by weekly donations at church, by legacies, and by the ſums which the church demands on the emancipation of ſlaves. The amount of the funds belonging to the reformed church in Cape town, in 1798, were 22,168l. 8s. 8d., and the ſubſiſtence granted to the poor was 1112l. 17s. The funds of the Lutheran church were 14,829l. 13s. 2d., and the relief granted to the poor 194l. 9s. 2d.

Cape *diſtrict*, is the ſmalleſt, but the moſt populous, of the four diſtricts into which the ſettlement of the Cape of Good Hope is divided. It conſiſts of two parts; one, the peninſula on which the Cape Town is ſituated; the other, the ſlip of land extending from the ſhore of Table bay to the mouth of the Berg river in St. Helena bay, and ſeparated from Stellenboſch and Drakenſtein, on the eaſt, by the little Salt river, Deep river, and Moſſel bank river; being about 80 miles from north to ſouth, and 25 from eaſt to weſt, and containing about 2000 ſquare miles. The cape peninſula is about 30 miles in length, and 8 in breadth, or 240 ſquare miles. Of the Cape diſtrict there is not one-fifteenth part of the ſurface under any kind of tillage. The produce of the Cape peninſula is grapes, with all the European and many of the tropical fruits, vegetables of every deſcription, barley for the uſe of horſes, and a ſmall quantity of choice wine. The other parts of the Cape diſtrict furniſh wheat, barley, pulſe, and wine. The population of this diſtrict in 1797 amounted to 18,152 perſons, of whom 6261 were Chriſtians, and 11,891 ſlaves; of the Chriſtians or free people, 718 are perſons of colour, and 1000, nearly, are Europeans. By comparing the average number of deaths with the population, it appears that the mortality in the Cape diſtrict is about $2\frac{34}{100}$ in the hundred. That of the ſlaves is rather greater, but leſs, perhaps, than in any other country, where ſlavery is tolerated. The number of deaths on the average of 8 years, was 350, which is after the rate of 3 in 100. The quantity of land occupied amounted in conſequence of a meaſurement not very correct to 8018 morgen, or 16,036 acres; of which 580 morgen were employed in vineyards and gardens, and 3089 in grain. Capital crimes in this diſtrict are not ſo numerous as might be ſuppoſed among ſuch a mixed multitude, the great majority of which have no intereſt in the public proſperity or tranquillity. As to the natural produce of this diſtrict, it is of little or no importance, if we except the fiſheries. The collecting of ſhells for lime, and of heaths and other ſhrubby plants for fuel, furniſh conſtant employment for about 1000 ſlaves.

It has been generally aſſerted, that the Cape peninſula was originally ſeparated from the continent of Africa; and this opinion has been founded on a ſuppoſed retreat of the ſea. Mr. Barrow, on the contrary, apprehends that the ſea is gaining upon the land in Southern Africa; and adduces ſeveral facts in ſupport of this hypotheſis. From all the obſervations which he had an opportunity of making on the ſouthern coaſt of Africa he concludes, that the whole of L'Aguillas bank, ſtretching from Cape Point acroſs the entrance of Falſe bay to the mouth of Rio Infante or the great Fiſh river, and to the 37th parallel of ſouthern latitude, has at one time formed a part of the continent. It has been alleged indeed in favour of the Cape iſthmus having, at no long interval of time, been covered with the ſea, that ſea-ſhells have been found on the ſand that is accumulated on its ſurface. In reply to this argument Mr. Barrow obſerves, that whole ſtrata of theſe may be found in the ſides of the Lion's hill, many hundred feet above the level of the ſea; and theſe ſhells, he adds, have been conveyed to that ſituation not by the waves of the ocean, but by birds: and they are frequently found even on the very ſummit of the Table mountain.

Cape *Town*, the capital of the colony, is ſituated on the ſouth-eaſt angle of Table bay. The ſettlers ſeem to have choſen this ſpot for the ſite of the town for the convenience of water, which ruſhes in a plentiful ſtream out of the Table mountain. Saldanha bay would, in other reſpects, have been more ſuitable; as Table bay is faulty in every point that conſtitutes a proper place for the mart of ſhipping; and ſo boiſterous for four months in the year, as totally to prevent all ſhips from entering into it. The town is built with great regularity; the ſtreets being all laid out with a line. The houſes are generally white-waſhed, and the doors and windows painted green; they are moſtly two ſtories in height, flat-roofed, with an ornament in the centre of the front, or a kind of pediment; with a raiſed platform before the door having a hut at each end. It conſiſts of 1145 dwelling-houſes, inhabited by about 5500 whites and people of colour, and 10,000 blacks. The firſt claſs is compoſed of thoſe who fill the ſeveral departments of government, the clergy, the members of the court of juſtice, and of the police. The next are a ſort of gentry who, having eſtates in the country, retail the produce of them by means of their ſlaves: ſubordinate to theſe is a number of petty dealers, who call themſelves merchants; and, laſtly, the tradeſmen who carry on their ſeveral profeſſions by their blacks. Many of the people of colour are fiſhermen. The ſalaries of thoſe who are employed in the different departments of government, are ſo ſmall that moſt of them are petty merchants. The country boors employ a ſort of agents, who keep houſes to lodge them when they make their annual viſit to the town. Theſe are a kind of Jew brokers, who ſubſiſt by defrauding the ſimple boors in the diſpoſal of their property, and in the purchaſe of neceſſaries for them on their return. The emancipated ſlaves and people of colour are generally artificers; and many of them ſupport their families by taking fiſh, of which there are great plenty and variety in Table bay. Upon the whole, the people of the town are an idle diſſolute race of men, ſubſiſting chiefly on the labour of their ſlaves, who are required to bring them a certain ſum at the end of every week, and what they earn above this ſum belongs to themſelves, by means of which ſome of thoſe who are the moſt induſtrious have been enabled to purchaſe their own freedom, and ſometimes that of their children. The price of proviſions and that of labour bear no proportion. Butchers' meat is about 2d. a pound, and good brown bread, ſuch as the ſlaves eat, 1d. a pound. A common labouring ſlave gets from 2s. to 2s. 6d. a day, and a mechanic or artificer 5 and 6 ſhillings a day. The people of Cape Town are almoſt all of them petty dealers, and they have a remarkable propenſity for public vendues. Theſe vendues are a kind of lottery; in which a man buys in the morning a ſet of goods, which he again expoſes for ſale in the evening, ſometimes gaining, and ſometimes loſing by his bargains.

Such is the rage for theſe vendues, that in four ſucceſſive months of the year 1801, the amount of property ſold by public auction was 1,500,000 rix-dollars, a ſum equal to the whole quantity of paper money in circulation, which may be conſidered as the only money which has of late been circulated in the country. Houſe rent, fuel, and clothing are dear in the Cape-town; and yet there is no city or town in Europe, where the maſs of the people are better lodged or better clothed. Fire is leſs neceſſary here than in moſt parts of Europe. During the continuance of the ſouth-eaſt winds, reſembling in their effect the ſouth-eaſt Sirocco of Naples, the town appears to be deſerted. Every door and window are cloſed to keep out the duſt and the heat, both of which decreaſe with the continuance of the gale; the air gradually cools, and every ſmall pebble and particle of duſt in the courſe of 24 hours are carried into the ſea. The north-weſt winds of winter produce a moiſt and cold feeling, even in Cape-town, where, though the thermometer ſeldom deſcends below 40°, and then only about an hour before ſun-riſe, all the Engliſh inhabitants are glad to keep conſtant fires during the months of July, Auguſt, and September. Even in October it is not unuſual to obſerve the ſummits of the mountain to the eaſtward of the Cape iſthmus buried in ſnow. The number of marriages in Cape-town comprehending thoſe of the whole colony, for eight years, from 1790 to 1797 incluſively, amounted to 1449; that of chriſtenings to 2589; and that of burials to 1173: ſo that 1416 was the exceſs of chriſtenings above burials in that period. The inhabitants of Cape-town are burthened neither with taxes nor aſſeſſments. At the firſt eſtabliſhment of the colony a kind of capitation tax was levied under the name of "Lion and Tiger money," the produce of which was applied towards deſtroying beaſts of prey; but ſince theſe animals have become ſcarce in the vicinity of the Cape, the name of the aſſeſſment is changed, but the fund ſupplied by it has been appropriated to the repairs of the roads, ſtreets, water-courſes, and other public works. Its ordinary amount is about 5000 rix-dollars a year. Another aſſeſſment, chargeable on heads of families at the rate of 1s. 6d. a month, for every houſe or fire-place, is called "Chimney and hearth money," and amounts to about 5200 rix-dollars yearly. The inhabitants of Cape-town are ſubject to no tithes nor church-rates; but as the church provides for the poor, every perſon manumitting a ſlave pays to it 10l. giving ſecurity that ſuch ſlave ſhall not become burdenſome for a certain number of years. The police of the town is committed to the management of a board, conſiſting of ſix burghers, called the "Burgher Senate." The pleaſures of the inhabitants are chiefly of the groſſer kind, being thoſe of eating, drinking, and ſmoking: they have no taſte for public amuſements, and no exerciſe but that of dancing. In the whole town there is neither a bookſeller's ſhop, nor a book ſociety. Under the direction of the church is a library, left by an individual, and conſiſting of many excellent books; but very little uſed. Books are rarely found in Cape-town to conſtitute any part of the furniture of a houſe. Education is ſo little regarded, that neither government nor the church has been able to raiſe a ſufficient ſum for eſtabliſhing a proper public ſchool in the colony; and few of the natives are in circumſtances that allow of their ſending their children for education to Europe.

One of the greateſt nuiſances in Cape-town is the number of dogs that prowl about the ſtreets, particularly by night, when they quit their dens and lurking places in queſt of the offals of butchers' ſhops. Sometimes the wolves and hyænas deſcend from their dens in the Table mountain, and diſpute the ſpoil with the dogs: at ſuch times the town reſounds with their hideous howlings through the whole night. Soon after the Dutch Eaſt India company formed a ſettlement at the Cape, they found it neceſſary to build a fort for the protection of their own property and that of other ſettlers and alſo of their warehouſes againſt the attempts of the natives. As their trade increaſed, and the Cape became more frequented, it was deemed expedient to extend the works, and to erect a citadel that ſhould ſerve as a defence againſt any attack, either by land or by ſea. This citadel is the preſent caſtle, a regular pentagon fort, with two ravelins and ſome other outworks, and ſurrounded by a wet ditch: but it is ſo injudiciouſly ſituated, that though it commands the town and part of the anchorage, it is itſelf commanded by the ground riſing from it in a ſlope to the Devil's hill, which therefore renders it indefenſible. This ſlope is now occupied as high as the commencement of the perpendicular rocky ſide of the Devil's hill, by various redoubts, batteries, and block-houſes, commanding each other, and the advance ground to the caſtle, all of which were added by ſir James Craig, when the Cape was in the poſſeſſion of England. He alſo made ſome other important additions to the fortifications of this place. Fort Knokke is connected with the citadel by a rampart drawn along the ſhore, called the "ſea lines," defended by ſeveral batteries, mounted with heavy guns, and furniſhed with ovens for heating ſhot. Within theſe lines is a powder magazine and a long range of low buildings that were converted under the Engliſh government into a general hoſpital, with lodgings for the inſpector, ſtore-keeper, and apothecary to the forces. On the weſt of the bay are three ſtrong batteries, viz. the Rogge-bay battery, the Amſterdam battery, and the Chavonne battery, all the guns of which bear directly upon the anchorage. There is alſo a ſmall battery, called the "Mouille," commanding the entrance of the bay. A little farther, on a ſmall ſandy cove, a work is thrown up with a few light guns and a heating furnace, for preventing a landing at this place, which is further impeded by three anchors fixed acroſs the inlet. At Camp's bay, on the weſtern coaſt of the peninſula, there are alſo a few ſmall batteries, and a military poſt on the height above it, directly between the Table mountain and the Lion's head. An army landing here, and at Three Anchor Bay, might take the town and all the batteries in their rear, or, by a more important movement, might get poſſeſſion of the Lion's rump, from whence, with a few howitzers, the town and citadel, and the ſtrong batteries on the weſt ſide of Table bay, would be completely commanded. This hill has the very great advantage of not being commanded by any other point. Sir James Craig propoſed to erect a citadel on this eminence with ſuitable appendages and accommodations, if the Cape had remained in our poſſeſſion, which would, in his opinion, be ably defended in time of war by 1200 men; and would render the town, the batteries, and the caſtle, untenable by an enemy, all of which might be totally deſtroyed from this height in 24 hours.

Beſides the caſtle and the forts, the other public buildings of Cape town are a large well conſtructed barrack for 2000 men; a quadrangular building with an area in the centre, where the government ſlaves are lodged to the number of nearly 400; the reformed church, which is a ſpacious and neat ſtructure; the Lutheran church; the town-houſe; the court of juſtice; and a theatre. The Cape of Good Hope is ſituated in S. lat. 34° 29′. E. long. 18° 23′ 15″. The town is in S. lat. 33° 55′ 42″. E. long. 18° 23′ 15″. Barrow's Travels into the interior of Southern Africa, &c. vol. i. and ii.

Cape *Verd* and *Iſlands.* See Verd.

CAPE, in *Law*, a writ judicial, touching plea of lands and tenements; ſo termed, from the word which carries the chief intention or end of it.

Cape is of two kinds, the *magnum* and *parvum*; which in their effect are alike, as to the taking hold of things immoveable; though in certain circumſtances they differ: 1. In that the *cape magnum*, or *grand cape*, lies before; and the *cape parvum*, or *petit cape*, after appearance. 2. *Cape magnum* ſummons the defendant to anſwer the default; and alſo over to the demandant: *cape parvum* only to the default. It is called *petit cape*, not becauſe of its ſmall force; but becauſe contained in few words.

CAPE *magnum* is thus defined in the old Nat. Brev. 162. "Where a man hath brought a *præcipe quod reddat* of a thing that touches plea of land, and the tenant makes default of the day to him given in the original writ; then this writ ſhall be for the king to take the land into his hands: and if the tenant come not at the day given him by the writ, he loſes his land."

CAPE *parvum*, or *petit cape*, is thus defined, ibid. "Where the tenant is ſummoned in plea of land, and comes at the ſummons, and his appearance is recorded; and at the day given him, prays the view; and having it granted, makes default; then ſhall this writ iſſue for the king, &c." Reg. Jud. fol. 1. 2. Bract. l. 3. tract. 3. c. i. Fleta. l. 2. c. 44.

CAPE *ad valentiam*, a ſpecies of *cape magnum*, ſo called from the end to which it tends: it is thus deſcribed, "Where I am impleaded of lands, and I vouch to warrant another, againſt whom the ſummons *ad warrantandum* hath been awarded, and he comes not at the day given; then, if the demandant recover againſt me, I ſhall have a writ againſt the vouchee; and ſhall recover ſo much in value of the lands of the vouchee, if he has ſo much: otherwiſe, I ſhall have execution of ſuch lands and tenements as deſcend to him in fee; or, if he purchaſe afterwards, I ſhall have a re-ſummons againſt him; and if he can ſay nothing, I ſhall recover the value." Old. Nat. Brev. 161.

CAPE *du Batardeau*, in *Fortification*, the cap, upper part, or roof of the batardeau conſtructed on the ditch of a work at the ſaliant angle of the baſtion. There is commonly raiſed or erected on the middle of it a ſmall tower or turret, ſix or ſeven feet, to prevent deſertion.

CAPECE, SCIPIO, in *Biography*, an eminent Latin poet of Italy, was born of a noble family at Naples towards the beginning of the 16th century, and began his career as profeſſor of juriſprudence in the univerſity of his native city, but afterwards directed his attention to polite literature. His houſe was the reſort of learned men, who produced in 1535 "Commentaries on Virgil," attributed to Donatus. He firſt attracted notice as a poet by three books in praiſe of St. John the Baptiſt, entitled "De Vate maximo." But his fame was chiefly owing to his poem in two books, "De Principiis Rerum," firſt printed in 1542, and dedicated to pope Paul III.; in conſequence of which, Bembo and Manuzio did not ſcruple to compare him, though without ſufficient reaſon, with Lucretius. This poem, with a tranſlation and learned notes of the abbé Ricci, was reprinted, together with the other poems of Capece, who appears to have been living in 1561, at Venice, in 1754. Gen. Dict. Triaboſchi.

CAPEDUNCULA, in *Roman Antiquity*, the veſſels wherein the ſacred fire of Veſta was preſerved. See VESTALS.

CAPEL, in *Geography*, a town of Germany in the duchy of Carinthia, on the Fella; 10 miles S. of Volkemarck.

CAPELAN, in *Ichthyology*, a name given by writers to a kind of whiting called by the Venetians matlo, and by obſolete authors aſellus omnium minimus, and merlangus. This is moſt probably gadus minutus of the moderns, which Belon calls merlangus, and is the ſmalleſt of its tribe. The merlangus of Geſner is certainly too large for the capelan, and appears to be the ſame with our common whiting, GADUS MERLANGUS.

CAPELINE, in *Military Language*, a ſort of iron head-piece, or helmet, which the cavalry under John, duke of Bretagne, uſed to wear.

CAPELINE, in *Surgery*, a kind of bandage uſed by the French ſurgeons in caſes of amputations; conſiſting of a roller with two equal heads.

CAPELL, EDWARD, in *Biography*, one of the numerous editors and commentators of Shakeſpeare, was born in the county of Suffolk, and died in 1781. His edition of Shakeſpeare, in 1768, was compriſed in 10 volumes, ſmall 8vo. with an "Introduction" of ſingular compoſition, announcing another work, which was publiſhed in 1783, under the title of "Notes and various readings of Shakeſpeare; together with the ſchool of Shakeſpeare, or Extracts from divers Engliſh books, that were in print in the author's time, evidently ſhewing from whence his ſeveral fables were taken, &c. &c." Mr. Capell was the editor of a volume of ancient poems, called "Proluſions;" and the alteration of "Antony and Cleopatra," as acted at Drury-lane in 1758. See SHAKESPEARE.

CAPELL, in *Geography*, a town of Germany, in the duchy of Stiria; 3 miles N. of Muertznſchlag.

CAPELLA, in *Aſtronomy*, a bright ſtar of the firſt magnitude, in the left or preceding ſhoulder of the conſtellation AURIGA.

CAPELLA, MATIANUS MINEUS FELIX, in *Biography*, an African Latin writer, who flouriſhed about the year 470, and is ſuppoſed to have reſided at Rome. He is author of a work in nine books, which conſiſts of proſe and verſe intermixed, upon the ſeven liberal arts. The title of his work is "De Nuptiis Philologiæ et Mercurii."

Of all his nine books, no one has been much noticed by the moderns, except the ninth, which treats of muſic. The few Romans who expreſsly treated that ſubject, and the eager deſire of claſſical readers to obtain ſome knowledge of the means by which the ancients produced, by the power of modulated ſounds, thoſe miraculous effects which are recorded, not only by poets, but hiſtorians and philoſophers, drew particular attention on this part of the work.

The author's plan is the following.

Perſonifying Philology and Harmony, or Poetry and Muſic, under the character of Mercury and Harmonia, he deſcribes their union as a nuptial feaſt, at which Jupiter and all the heavenly hoſt of Paganiſm attend; celebrates as terreſtrial cultivators of muſic, Orpheus, Amphion, and Arion, who are admitted among the celeſtials to partake of the entertainment. And after going over the old ground in relating the wonders which muſic has performed, in healing diſeaſes, quelling ſeditions, tempering and bringing to reaſon the irregular affections of unruly youth, Harmonia is deſired by Apollo and Minerva to unfold the myſtery of her art.

We ſhall not enter on a diſquiſition concerning the Latinity of this work, which by many critics has been termed barbarous, but confine our reflections to the information which inquirers into the arcana of ancient muſic are likely to derive from its peruſal.

The author explains, by the mouth of Harmonia herſelf, the Greek ſcale of tones and ſemitones, giving Latin tranſlations of the Greek muſical terms, proceeding from *Proſlambanomenos*, the loweſt ſound in the general ſyſtem, and mounting

ing up to *Hyperbolæon, ultima excellentiam.* The next period treats of conſonances; then of modes; of ſingle ſounds, harmonical parts of the ſyſtem; of intervals, genera, keys, tetrachords; of the diapente and diateſſaron, or 5th and 4th; of tranſitions; of melopœia, rhythm, three kinds—the dactylic, iambic, and pæonian; and of ſix kinds of compound rhythm.

This ninth book, according to Meibomius, may be regarded as divided into two parts; the firſt containing the hiſtory of muſic, and its eulogium, the ſecond the theory and precepts of the art itſelf; and this laſt is what we ſhall chiefly conſider, as to its utility. And in mercy to inquirers after Greek muſic, or the muſic of the ancients in general, we can aſſure them, that what has been ſo long ſought in vain among the ſeven Greek theoriſts publiſhed by Meibomius, in Ptolemy, Plutarch, and Boethius, will not be found in Martianus Capella. His definitions are awkward Latin tranſlations of what may be found not only in Ariſtides Quintilianus, but in every Greek writer on muſic. He has not given us one of the characters of either Greek or Roman *notation;* nor is there, either in his encomia or definitions, a word that encourages a belief that the ancients knew any thing of ſimultaneous harmony, or *muſic in parts;* or even a trait of the arrangement of ſingle notes, to enable us to form any judgment of their melody. The rhythms, of which ſo many are mentioned, are thoſe of verſe, which probably were likewiſe thoſe of muſic.

He was the firſt from whom we received equivalents in Latin for the Greek muſical technica, and we find in his poetry many new metres, which we do not recollect to have ſeen in any other Roman poet. The learned work of Capella was firſt publiſhed by Vitalis, in folio, at Venice, in 1499, in a very incorrect ſtate. The corrections of Hugo Grotius at the age of 14 are among the wonders of literary hiſtory. They were publiſhed at Leyden in 1599.

Another Capella, who was a writer of elegy, is commemorated by Ovid, "De Ponto."

CAPELLE, in *Geography*, a town of France, in the department of the Straits of Calais, and diſtrict of Montreuil; 1 league S. of Heſdin.

Capelle, La, a town of France, in the department of Aiſne, and chief place of a canton in the diſtrict of Vervins; 4 leagues N.E. of Guiſe. The town contains 1,077, and the canton 14,097 inhabitants; the territory includes 187½ kiliometres and 18 communes.

Capelle-Marival, La, a town of France, in the department of the Lot, and chief place of a canton in the diſtrict of Figeac; 8 miles N.N.W. of Figeac. The place contains 1,013, and the canton 12,128 inhabitants: the territory comprehends 215 kiliometres and 20 communes.

CAPELLEN, a town of Germany, in the duchy of Stiria; 8 miles W. of Luttenburg.

CAPELLETTI, a Venetian militia, compoſed of ſoldiers that partly were ſlaves, Dalmatians, Albanians, and Morlachians, and were regarded as the choiceſt and beſt troops of the ſtate of Venice. They were much confided in by the Venetians, and were employed to guard their places of the greateſt importance, and amongſt others the palace and place of St. Marck at Venice.

CAPELLUTIUS, Reland, in *Biography*, a diſtinguiſhed phyſician and philoſopher, who flouriſhed in the latter part of the 15th century, under the pontificate of Paul II. publiſhed in 1490, "Chirurgia," printed at Venice in fol. and reprinted with additions in 1519 and 1546. It contains the whole body of ſurgery, collected principally from Albucaſis, and other Arabian writers. A poſthumous work of this writer was publiſhed at Franckfort in 1642, 8vo. reprinted in 1648, 4to. and again in 1682, 8vo.; "De Curatione Peſtiferorum Apoſtematum;" a practical work, much eſteemed. Haller. Bib. Chir. Eloy Dict. Hiſt.

CAPENA, or *Capinna*, Steph. Byz. in *Ancient Geography*, a town of Italy in Etruria, between the country of the Veii and the Tiber, according to Livy, who places the wood and temple of Feronia within its territory. Virgil alſo mentions this city, which was nearly N. of Rome.

Capena was alſo the name of one of the gates of Rome, now the gate of St. Sebaſtian, S.E of Rome.

CAPENSIS, in *Conchology*, a ſpecies of Anomia. The ſhell is longitudinally ſtriated, ſlightly truncated, with roundiſh crenated margin; flat valve, with a two-ſpined rib beneath. Chemn. Inhabits the Cape of Good Hope. Shell ſometimes reddiſh, ſometimes white.

Capensis, in *Entomology*, a ſpecies of Bombylius, that inhabits Africa, the wings of which are ſpotted with black; body greyiſh and black at the extremity. Linn.

Capensis, a ſpecies of Phalæna, (Bombyx) that inhabits Africa. The wings are pale red; on the anterior pair two flexuous ſtreaks, the poſterior of which is connected to a black one.

Capensis, a Linnæan ſpecies of Cicindela. This kind is ſomewhat braſſy, with white wing-caſes marked with a three-branched fuſcous line. Inhabits the Cape of Good Hope, and Calabria.

Capensis, a ſpecies of Cerambyx, found at the Cape of Good Hope. The general colour is black; thorax two-ſpined; four rufous bands on the wing-caſes; antennæ moderate.

Capensis, a ſpecies of Carabus, deſcribed by Thunberg as a native of the Cape of Good Hope. This is of a ferruginous colour, with a black longitudinal line on the thorax and ſuture of the wing-caſes.

*Obſ.* The abdomen in ſome ſpecimens is black; in others brown.

Capensis, in *Ornithology*, a ſpecies of Alauda, that inhabits the Cape of Good Hope. The three lateral feathers of the tail are tipped with white; chin pale yellow, edged with black; eye-brows yellow: *Cape lark*, Latham; *alauda capitis bonæ ſpei*, Briſſon; and *cravate jaune ou calandre du cap de bonne eſpérance*, Buffon. The bill is yellowiſh brown; upper part of the body with the tail brown; all the feathers darkeſt in the middle; chin orange; body beneath ochraceous; legs black; back claw rather hooked.

Capensis, a ſpecies of Anas, of a greyiſh colour, with cheſnut-coloured back, and ſpeculum ſpot on the wing pale greeniſh blue, edged with white.

This is the *cape wigeon* of Latham. The length is fifteen inches; bill red, black at the baſe; head ſpotted; legs reddiſh; claws black. Inhabits the Cape of Good Hope.

Capensis, a ſpecies of Alcedo. This has the tail long, and of a cinereous blue colour; beneath fulvous; breaſt teſtaceous; bill red. Gmel.

This bird inhabits the Cape of Good Hope. Its length is fourteen inches. The bill is blackiſh at the tip; head grey, inclining to tawny; body above blue green, inclining to aſh on the back; legs and claws red. Briſſon calls it *iſpida capitis bonæ ſpei;* and Buffon, *martin-pecheur du cap de bonne eſpérance.*

Capensis, a ſpecies of Certhia, that inhabits the Cape of Good Hope. The colour is fuſcous; tail-feathers blackiſh, the exterior ones fringed at the outer edges with white. Briſſon, &c.

CAPER-*bean*, in *Botany*. See Zygophyllum.

Caper-*buſh*. See Capparis.

Caper, or Caprus, in *Ancient Geography*, a river of

Aſia, in Syria, which flowed between the Lycus and Gorgus, and diſcharged itſelf into the Tigris. Ptolemy.—Alſo, a river of Aſia Minor, in Phrygia, and in the country of Cilaritis. Pliny ſays that it waſhed one of the ſides of Laodicea; and Strabo informs us, that it diſcharged itſelf into the Meander, near that city.

Caper, in *Navigation*, a veſſel uſed by the Dutch, for cruiſing and taking prizes from the enemy. In which ſenſe caper amounts to the ſame with privateer. Capers are commonly double officered, and crowded with hands even beyond the rates of ſhips of war, becauſe the thing chiefly in view is boarding the enemies.

CAPERNAUM, in *Ancient Geography*, a town of Paleſtine, ſituate on the north ſide of the ſea of Tiberias, called alſo the lake of Genneſareth and Sea of Galilee, at ſome diſtance weſt from the mouth of Jordan. Although it ſtood till the ſeventh or eighth century, its preciſe ſituation is quite loſt. According to St. Matthew, (iv. 13.) it was on the borders of Zabulon and Nephthali; and it was celebrated as the place where Chriſt dwelt after leaving his family at Nazareth, and where he performed many miracles, which occaſioned the woe denounced againſt its inhabitants for their infidelity. Capernaum was alſo the name of a river and of a mountain in the vicinity of the town. It had alſo a ſpring of clear and limpid water, which might probably induce the Jews, after their return from the Babyloniſh captivity, to build a city near it.

CAPEROLANS, in *Eccleſiaſtical Hiſtory*, a congregation of religious in Italy, ſo called from Peter Caperole their founder, in the 15th century. Caperole having by his enterprizing ſpirit and influence ſeparated the convents of Breſcia, Bergamo, and Cremona, from the province of Milan, a law-ſuit between the vicar-general and theſe convents enſued, which terminated in their favour. In 1475, pope Sixtus IV. erected them into a diſtinct vicariate under the title of that of Breſcia. Caperole afterwards induced the Doge of Venice to erect this vicariate into a congregation diſtinguiſhed by his own name. It ſtill ſubſiſts, and comprehends 24 convents, ſituate in Breſcia, Bergamo, and Cremona.

CAPES, or Capez, in *Geography*. See Gabs.

CAPESTANG, a town of France, in the department of Herault, and chief place of a canton, in the diſtrict of Beziers; 3 leagues N. of Narbonne. The place contains 1350, and the canton 5767 inhabitants; the territory comprehends $247\frac{1}{2}$ kiliometres, and 9 communes.

CAPET, Hugh, in *Biography*, the firſt king of France of the third race, was the ſon of duke Hugo, ſurnamed the Great, who, without wearing the crown, had for the beſt part of his life held the ſupreme power in France, and who died A. D. 955, by Hadwiga, or Avoya, of Saxony, daughter to Henry the Fowler, king of Germany, ſiſter to the emperor Otho the Great, and to Gerberg queen of France. Dante, in his "Purgatory," (Canto 20) in order to be revenged on prince Charles of Valois, ſprung from this prince, for drawing him from Florence, and confiſcating his property, when he headed one of the factions of the city, traduced his family by repreſenting him to be the ſon of a butcher. This ridiculous falſity has been adopted and circulated by ſeveral writers on the authority of Dante. Whereas his father was the ſon of king Robert, who fixed the Normans in France, brother-in-law to three kings, viz. Rodolph, Athelſtan, and Otho the Great, and deſcended by his mother from Charlemagne. As to the ſurname of "Capet," it was moſt probably a nick-name, ſignifying literally "jolterhead," and metaphorically, a "weak," or an "obſtinate" man. In the firſt of theſe ſenſes it was applied to Charles the Simple, and, perhaps, in the latter ſenſe, to this prince in his youth. At the death of his father he was 16 years of age, and he was particularly recommended to the care of Richard, duke of Normandy. When the line of Charlemagne, which had poſſeſſed the throne between 230 and 240 years, terminated with Lewis V. the laſt monarch of that line, Hugh Capet, who had ſerved him faithfully during his reign, ſucceeded him; the crown, as ſome writers aſſert, having been bequeathed to him by Lewis in recompence of his ſervices. However this be, upon the death of the king Hugh Capet took early and effectual meaſures for ſecuring the throne; as in a few days he cauſed himſelf to be proclaimed king at Noyon, and was ſolemnly crowned at Rheims, by the archbiſhop of that ſee, on the 3d of July, A. D. 987. This deſign was executed without oppoſition, nor did any perſon exert himſelf in behalf of the late king's uncle Charles, the laſt ſurviving prince of the race of Charlemagne. On his acceſſion, he added greater ſtrength to the crown than he received from it; ſince the duchy of France, the countries of Paris and Orleans, were in his own hands, and his brother-in-law, the duke of Normandy, was cloſely attached to his intereſt. His own queen Adelaide, who is ſaid to have been a princeſs of high birth and admirable qualities, contributed in no ſmall degree to his ſecurity. Having defeated an army raiſed by William duke of Guienne, in a ſhort but bloody battle near Poitiers, he compelled him to ſubmit; and being a man of good temper and ſagacity, as well as of great moderation, he aſſembled the nobles and propoſed to them the aſſociation of his ſon Robert. The propoſal being accepted, Robert was crowned with great ceremony on new-year's day, A. D. 988, at Orleans, by the archbiſhop of Sens. Having, by this act, ſecured the crown to his family, he never afterwards wore the royal ornaments, or affected any extraordinary ſtate or magnificence; but adminiſtered public affairs with great application, and with ſuch an appearance of modeſty, juſtice, and piety, as recommended him highly to his ſubjects, and more eſpecially to the clergy, to whom he reſtored all the abbies in his poſſeſſion; and his example was followed by the nobility. In the following year the adherents of Charles of Lorrain, after an unſucceſsful conteſt, did homage to the kings Hugh and Robert. The duke Lorrain remained, as long as he lived, a priſoner at Orleans; and with his ſon, who enjoyed the duchy of Lorrain, and who died without male iſſue, A. D. 991, the male line of Charlemagne was entirely extinct. In the ſequel of his reign, Hugh Capet ſtrengthened his government by mildneſs and moderation, and had the ſingular honour of eſtabliſhing a new family, and in ſome meaſure a new form of adminiſtration, without any remarkable circumſtances of violence, and without ſhedding blood. He died on the 24th of October, A. D. 997, in the 57th year of his age, and in the 8th of his reign, leaving his dominions in perfect tranquillity, and his ſon Robert in the peaceable poſſeſſion of the crown. His remains were interred in the church of the abbey of St. Denis. The deſcendants of Hugh Capet governed the kingdom of France, in a direct line from father to ſon, terminating with Charles IV. ſurnamed the "Fair," for eleven generations. There were thirteen monarchs in all, whoſe reigns together make upwards of 340 years, during which interval they wonderfully extended their authority as well as their dominions; and recovered, either to the crown or to the princes of the royal family, the better part of the ancient kingdom of France. They had alſo reduced the exorbitant power of the nobility within bounds, and were much leſs dependent upon the clergy than the monarchs of the ſecond race. Yet, after all, the nation was in low circumſtances; the frame of government far from being uniform;

form; and, in ſhort, the ſeeds of thoſe diſorders were very perceptible to diſcerning perſons, which, in the ſucceeding reign, ſprang up and became viſible to the whole world in their diſmal effects. Gen. Dict. Mod. Un. Hiſt. vol. xix. and xx.

CAPH, a Jewiſh meaſure of capacity, eſtimated by Kimchi at the 30th part of the log, by Arbuthnot at the 16th part of the hin, or 32d of the ſeah, amounting to five-eighths of an Engliſh pint. The caph does not occur in Scripture as the name of any meaſure.

CAPHAR, a toll, or duty, impoſed by the Turks on the Chriſtian merchants, who carry or ſend merchandiſes from Aleppo to Jeruſalem.

The caphar was firſt ſettled by the Chriſtians themſelves, when maſters of the Holy Land, for the ſupport of troops and forces poſted in the more difficult paſſes, to watch the Arabs, and prevent their pillages. But the Turks, who have continued, and even raiſed the toll, abuſe it; exacting arbitrary ſums of the Chriſtian merchants and travellers, on pretence of guarding them from the Arabs: with whom they yet frequently keep an underſtanding, and even favour their robberies.

Caphar, Heb. denoting a field or village, in *Ancient Geography*, is often uſed, in compoſition with other words, to ſignify a particular town or city. Thus, *Caphar-Aria*, a village of Paleſtine, between Jeruſalem and Aſcalon:—*Caphar-Barica*, or *Caphar Barucha*, a village of Paleſtine, 3 miles from Hebron, in the tribe of Juda, mentioned by Epiphanius and Jerome:—*Caphar-Dagon*, ſituate between Dioſpolis and Jamnia:—*Caphar-Nimra*, a populous town of Paleſtine, in the land of Iſrael:—*Caphar-Nome*, a village of Paleſtine, in Galilee, near Jordan:—*Caphar-Orſa*, a town of Idumæa, placed by Ptolemy to the weſt of Jordan:—*Caphar-Saba*, the ſite of *Antipatris*, which ſee:—*Caphar-Samala*, a place near Jeruſalem:—*Caphar-Sorek*, a town of Paleſtine, near Eleutheropolis, which exiſted in the time of Jerome.

CAPHARA, a town of Judah, in the tribe of Benjamin.

CAPHARATH, a fortified village of Galilee. Joſephus.

CAPHARCOTIA, or Caparcotia, a town of Paleſtine in Galilee, between Scythopolis and Cæſarea of Paleſtine.

CAPHAREUS, a promontory of the iſland of Eubœa, the doubling of which was reckoned very dangerous, in the infancy of navigation, on account of the rocks and whirlpools on that coaſt, much ſpoken of by the ancients. It is now called Capo d'Oro, Capo Chimi, and Capo Figera. On this coaſt the Grecian fleet was ſhipwrecked on its return from Troy with Agamemnon. To this purpoſe Virgil ſays (Æneid. l. xi. v. 260.):

> "Sit triſte Minervæ
> Sidus, et Euböica cautes, ultorque Caphareus."

CAPHAS, a mountain of Interior Libya, ſituated in that part of Africa which is about the 15th degree of N. latitude, and 25th degree of E. longitude, whence, according to Ptolemy, the river Daradus aroſe, ſuppoſed by ſome to be the preſent Senegal, and from which, it is conjectured, the Levant wind, called the Harmattan, proceeds. See Harmattan.

CAPHESA, or Capsa, a town of Africa, near the ſource of the river Magrada, ſurrounded by deſerts. Ptol. and Strabo.

CAPHIÆ, or Caphya, a town of Peloponneſus in Arcadia, N.W. of Orchomenus; it was built by Cepheus, and peopled from Attica. In this city were temples of Neptune and Diana. It ſuffered much from the enterpriſes of Cleomenes and the Achæan league. Near it was a fountain ſhaded by a plantain tree of extraordinary beauty, ſaid to have been planted by Menelaus, when he came into Arcadia to raiſe troops for his Trojan expedition. In the time of Pauſanias an antiquity of 1362 years was aſcribed to the tree. Pliny (l. xvi.) ſays, that it was planted by Agamemnon.

CAPHTOR, an iſland or diſtrict, concerning the ſituation of which Scripture interpreters have differed. Some have ſuppoſed, without ſufficient reaſon, that it was Cappadocia. Others are of opinion, that the iſland called Caphtor, from which ſprung the Caphtorim, Cherethites, or Philiſtines, who are thought to be people of the ſame origin, was the iſle of Crete in the Mediterranean. The abbé Pluche, Dr. Wells, and others, with greater probability, ſuppoſe Caphtor to have been one of the iſlands formed by the Nile in Egypt, and that it was the ſame with *Coptos*, which was ſo ſituated. To this purpoſe it is alleged, that the Caphtorim, mentioned Gen. x. 14. were deſcendants of Mizraim, the ſon of Ham, who peopled Egypt; and from them ſprung the Philiſtines.

CAPHURA, the ſame with *camphor*, which ſee.

CAPI-AGA, or Capi-Agassi, a Turkiſh officer, who is governor of the gates of the ſeraglio; or grand maſter of the ſeraglio. The capi-aga is the firſt dignity among the white eunuchs: he is always near the perſon of the grand ſignior: he introduces ambaſſadors to their audience: nobody enters, or goes out of the grand ſignior's apartment, but by his means. His office gives him the privilege of wearing the turban in the ſeraglio, and of going every where on horſeback. He accompanies the grand ſignior to the apartment of the ſultanas, but ſtops at the door without entering. His appointment is very moderate; the grand ſignior bears the expence of his table, and allows him at the rate of about ſixty French livres per day; but his office brings him in abundance of preſents; no affair of conſequence coming to the emperor's knowledge, without paſſing through his hand. The capi-aga cannot be baſhaw when he quits his poſt.

CAPIAS, in *Law*, a writ or proceſs, which is of two ſorts; one before judgment, in the court of C. P. called *Capias ad reſpondendum*, where an original is ſued out, &c. to take the defendant and make him anſwer the plaintiff. The other is a writ of execution after judgment, which is of various kinds; as, *Capias ad ſatisfaciendum*, *Capias pro fine*, *Capias utlagatum*, &c.

The *Capias ad reſpondendum* in C. B. is drawn from the "præcipe," which ſerves both for the "original" and "capias," and the return of the original is the teſte of the "capias." If a "capias" be ſpecial, in caſe, covenant, &c. the cauſe of action muſt be recited at large, and the ſubſtance of the intended declaration ſet forth, as alſo in the original. The "capias" is a writ commanding the ſheriff to take the body of the defendant, if he may be found in his baliwick or county, and to keep him ſafely, ſo that he may bring him to court, on the day of the return, to anſwer to the plaintiff of a plea of debt, treſpaſs, &c. In caſes of injury accompanied with force, the law, to puniſh the breach of the peace, and to prevent its diſturbance for the future, provided a proceſs againſt the defendant's perſon, in caſe he neglected to appear on the proceſs of attachment againſt his goods, or had no ſubſtance by which to be attached, ſubjecting by this writ his body to impriſonment. 3 Rep. 12. But the immunity of the defendant's perſon, in caſe of peaceable though fraudulent injuries, producing great contempt of the law in indigent wrong-doers, a "capias" was alſo allowed to arreſt the perſon in actions of "account," though no breach of the peace be ſuggeſted, by the ſtats. of Marlbridge, 52 Hen. III. c. 23. and Weſtm. 2. 13 Edw. I. c. 11.; in actions of "debt" and "detinue," by ſtat. 25 Edw. III. c. 17.; and in all actions "on the caſe," by ſtat. 19 Hen. VII.

c. 9. Before this laſt ſtatute a practice had been introduced of commencing the ſuit by bringing an original writ of treſpaſs, “quare clauſum fregit,” for breaking the plaintiff’s cloſe, “vi et armis;” which by the old common law ſubjected the defendant’s perſon to be arreſted by writ of “capias;” and then afterwards, by connivance of the court, the plaintiff might proceed to proſecute for any other leſs forcible injury. This practice (through cuſtom rather than neceſſity, and for ſaving ſome trouble and expence, in ſuing out a ſpecial original, adapted to the particular injury) ſtill continues in almoſt all caſes, except in actions of debt; though now, by virtue of the ſtatute above cited, and others, a “capias” might be had upon almoſt every ſpecies of complaint. It is now uſual in practice, to ſue out the “capias” in the firſt inſtance, upon a ſuppoſed return of the ſheriff (that the defendant, being ſummoned or attached, made default, or that he had no ſubſtance by which to be attached); eſpecially if it be ſuſpected that the defendant, upon notice of the action, will abſcond; and afterwards a fictitious original is drawn up, if the party is called upon ſo to do, with a proper return thereupon, in order to give the proceedings a colour of regularity. When this “capias” is delivered to the ſheriff, he by his under-ſheriff grants a warrant to his inferior officers, or bailiffs, to execute it upon the defendant. If the ſheriff of the county, in which the injury is ſuppoſed to be committed, and the action is laid, cannot find the defendant in his juriſdiction, he returns “non eſt inventus;” whereupon another writ iſſues, called a “teſtatum capias,” directed to the ſheriff of the county where the defendant is ſuppoſed to reſide, reciting the former writ, and that it is teſtified “teſtatum eſt,” that the defendant lurks or wanders in his bailiwick, wherefore he is commanded to take him, as in the former “capias.” But in a caſe of this kind alſo, it is uſual, for ſaving trouble, time, and expence, to make out a “teſtatum capias” at the firſt; ſuppoſing not only an original, but alſo a former “capias” to have been granted. This fiction, being beneficial to all parties, is readily acquieſced in, and is now become the ſettled practice. But where a defendant abſconds, and the plaintiff would proceed to an outlawry againſt him, an original writ muſt then be ſued out regularly, and after that a “capias.” And if the ſheriff cannot find the defendant upon the firſt writ of “capias,” and returns “non eſt inventus,” there iſſues out an “alias” writ, and after that a “pluries,” to the ſame effect as the former; only after theſe words, “we command you,” this clauſe is inſerted, “as we have *formerly*,” or “as we have *often* commanded you;” “*ſicut* alias, or *ſicut* pluries, præcipimus.” In the King’s-bench, the bill of Middleſex is a kind of “capias.” See Bill *of Middleſex*.

A “capias” is alſo uſed in criminal, as well as in civil, caſes. The proper proceſs on an indictment for any petty miſdemeanor, or on a penal ſtatute, is a writ of “venire facias,” which is in the nature of a ſummons to cauſe the party to appear. If by the return to ſuch “venire” it appears, that the party hath lands in the county, whereby he may be diſtrained, then a “diſtreſs infinite” ſhall be iſſued from time to time till he appears. But if the ſheriff returns that he hath no lands in his bailiwick, then (after his non-appearance) a writ of “capias” ſhall iſſue, which commands the ſheriff to take his body, and have him at the next aſſizes; and if he cannot be taken upon the firſt “capias” a ſecond and a third ſhall iſſue, called an “alias,” and a “pluries capias.” But on indictments for treaſon or felony, a “capias” is the firſt proceſs; and, for treaſon or homicide, only one ſhall be allowed to iſſue, or two in the caſe of other felonies, by ſtat. 25 Edw. III. c. 14.; though the uſage is to iſſue only one in any felony; the proviſions of this ſtatute being in moſt caſes found impracticable. Alſo, in the caſe of miſdemeanors, it is now the uſual practice for any judge of the court of King’s-bench, upon certificate of an indictment found, to award a writ of “capias” immediately, in order to bring in the defendant. But in this, and alſo in civil caſes, if he abſconds, and it is thought proper to purſue him to outlawry, greater exactneſs is neceſſary. Blackſt. Com. v. iii. 282, &c. v. iv. p. 318, &c.

Capias *ad ſatisfaciendum*, commonly termed CA. SA., is a writ of execution after judgment; lying where a man recovers in an action perſonal, as for debt, damage, &c. in which caſes, this writ iſſues to the ſheriff, commanding him to take the body of him againſt whom the debt is recovered; who is to be kept in priſon till he make ſatiſfaction.

It is uſual to take out this writ, where the defendant hath no lands nor goods, whereof the debt recovered may be levied: and when the body is taken upon a *Ca. Sa.* and the writ is returned and filed, it is an abſolute and perfect execution againſt the defendant, and no other execution can be had againſt his lands and goods. But this is unleſs the defendant eſcape, or die in execution, &c. for where a perſon dies in execution, his lands and goods are liable to ſatisfy judgment, by ſtat. 21 Jac. I. c. 24. Rol. Abr. 904. This writ does not lie againſt any privileged perſons, peers, or members of parliament; nor againſt executors or adminiſtrators (except on a “devaſtavit” returned by the ſheriff, 1 Lill. 250); nor againſt ſuch other perſons as could not originally be held to bail. It may be ſued out for coſts, againſt a plaintiff as well as a defendant, when judgment is had againſt him. If the defendant cannot be taken upon a *Ca. Sa.* in the county where the action is laid, there may iſſue a “teſtatum” *Ca. Sa.* into another county, and ſo of the other writs.

Capias *pro fine.* When judgment is given for the plaintiff, it is conſidered that the defendant be either amerced, for his wilful delay of juſtice in not immediately obeying the king’s writ by rendering the plaintiff his due; or be taken up, “capiatur” till he pays a fine to the king for the public miſdemeanor which is coupled with the private injury, in all caſes of force, of falſehood in denying his own deed, or unjuſtly claiming property in replevin, or of contempt by diſobeying the command of the king’s writ or the expreſs prohibition of any ſtatute. But now in caſe of treſpaſs, ejectment, aſſault, and falſe impriſonment, it is provided by 5 & 6 W. & M. c. 12., that no writ of “capias” ſhall iſſue for this fine, nor any fine be paid; but the plaintiff ſhall pay 6s. 8d. to the proper officer, and be allowed it againſt the defendant among his other coſts. And, therefore, upon ſuch judgments in the Common Pleas they uſed to enter that the ſame was remitted; and now in both courts they take no notice of any fine or “capias” at all. Blackſt. tom. v. iii. p. 398.

Capias *utlagatum*, a writ which lies againſt one outlawed upon any action, perſonal or criminal; by which the ſheriff is ordered to apprehend the party outlawed, for not appearing on the exigent, and keep him in ſafe cuſtody till the day of return; when he is to preſent him to the court, to be there further dealt with for his contempt: who, in the Common Pleas was formerly to be committed to the Fleet, and to remain there till he had ſued out the king’s pardon, and appeared to the action. By a ſpecial “Capias utlagatum” (againſt the body, lands, and goods in the ſame writ) the ſheriff is commanded to ſeize all the defendant’s lands, goods, and chattels, for the contempt to the king; and the plaintiff, (after an inquiſition taken thereupon, and returned into the exchequer) may have the lands extended, and a grant of the goods, &c. whereby to compel the defendant to appear; which when he doth, if he reverſe the outlawry, the ſame ſhall be reſtored to him. Old. Nat. Brev. 154. When a perſon is taken upon a "capias utlagatum," the ſheriff is to take an attorney's engagement to appear for him, where ſpecial bail is not required; and his bond with ſureties to appear, where it is required. Stat. 4. & 5. W. & M. c. 18. See Outlawry.

Capias *in Withernam.* See Withernam.

Capias *conductos ad proficiſcendum*, an original writ, which lies, by the common law, againſt any ſoldier who has covenanted to ſerve the king in war, and appears not at the time and place appointed. It is directed to two of the king's ſerjeants at arms, to arreſt and take him wherever he may be found: and to bring him *coram concilio noſtro*, with a clauſe of aſſiſtance.

CAPIATUR, *judgment quod.* See Capias *pro fine.*

CAPIBARA. See Capybara.

CAPICULY, formerly called Janizaries, the firſt and beſt corps or body of the Turkiſh infantry.

CAPIDAVA, in *Ancient Geography*, a town of Lower Mœſia, between Axiopolis and Carſon. Antonin. Itin.

CAPIDODIUS, in *Zoology*, a name given by Paulus Jovius, and ſome other obſolete writers, to an animal of the cetaceous tribe (or fiſh as they deſcribe it) diſtinguiſhed by having the ſnout bending upwards, and armed with broad ſerrated teeth. The ſpecies implied is certainly Delphinus Orca of Linnæus and later authors.

CAPIDOLIA, in *Zoology*, a ſynonym of Balæna Musculus.

CAPIGI, or Capidgi, a porter, or door keeper of the Turkiſh Seraglio. There are about five hundred capigis, or porters, in the Seraglio, divided into two companies; one conſiſting of three hundred, under a chief called *Capigi-Baſſa*, who has a ſtipend of three ducats per day; the other conſiſts of two hundred, diſtinguiſhed by the name of *Cuccicapigi*, and their *chief Cuccicapigi-Baſſa*, who has two ducats. The capigis have from ſeven to fifteen aſpers per day; ſome more, others leſs. Their buſineſs is to aſſiſt the janizaries in the guard of the firſt and ſecond gates of the Seraglio; ſometimes all together; as when the Turk holds a general council, receives an embaſſador, or goes to the moſque; and ſometimes only in part; being ranged on either ſide to prevent people entering with arms, any tumults being made, &c. The word, in its original, ſignifies *gate.*

CAPIGIS-*bachis*, or Capidgis-*bachis*, a ſort of chamberlains belonging to the grand ſignior whoſe place is honourable and lucrative, and who are charged to execute the orders which they receive from the ſultan, e. g. to cut off the head of a rebel or extortioner, to carry the news of the appointment to a government, to go and collect the ſucceſſions of the great officers of the empire, &c.; their chief, always taken from this claſs, is called "Mir-alem." The capidgis-bachis are ſometimes raiſed to the dignity of pacha or baſhaw with two tails, and go in that quality to govern the province which is allotted to them.

CAPILLAIRE, a ſyrup made of maiden-hair. See Adiantum and Asplenium.

CAPILLAMENT, literally ſignifies *hair*, being formed of the Latin *capillus*, of *caput*, q. d. *hair of the head.* Hence the word is figuratively applied to ſeveral things, which, on account of their length, or their fineneſs, reſemble hairs: as,

Capillaments *of the nerves*, the fine fibres, or filaments, whereof the nerves are compoſed.

Capillament, in *Botany*, a term uſed by the old botaniſts for the filament of the ſtamen. Bradley ſeems to reſtrain *capillaments* to the ſmaller flowers; and *ſtamina* (which he corruptly calls *apices*) to the larger.

Capillament is alſo applied to the ſtrings or threads about the roots of plants.

CAPILLARES, a name given by ſome of the old botaniſts to the ferns, becauſe, according to Mr. Ray, they ſtrengthen and improve the human hair; or, according to others, from a curious fancy that they grow from the earth without ſtems, in the ſame manner as hairs grow from the human head.

CAPILLARIS, or Capillata, *Arbor*, an ancient tree at Rome, on which the veſtal virgins, when ſhaven for their office, hung up their hair, and conſecrated it to the gods.

CAPILLARY, of the Latin *capillus*, a *hair*, is applied to ſeveral things, to intimate their exceeding ſmallneſs or fineneſs, reſembling that of a hair.

Capillary is alſo uſed by *Mineraliſts* in ſpeaking of ores which ramify or ſhoot out fine branches like threads.

In which ſenſe it amounts to the ſame with what is otherwiſe called *arboreſcent* and *ſtriated.* Woodward ſpeaks of capillary or arboreſcent ſilver and iron; Grew deſcribes a piece of pure capillary copper from the mine of Heragrunt, the ſeveral ſtriæ or capilli of which are ſhort, of a reddiſh golden colour, growing together almoſt like thoſe of the little ſtone-moſs.

Capillary *roots.* See Fibrose *roots.*

Capillary *tubes*, in *Phyſics*, are thoſe which are very ſmall, or whoſe canals are ſo narrow, as by the diminutive ſize of their bores to reſemble a hair in diameter. The uſual diameter of capillary tubes is a half, third, or fourth of a line, or from $\frac{1}{20}$th to $\frac{1}{50}$th of an inch: though Dr. Hook aſſures us he drew tubes in the flame of a lamp much ſmaller, and almoſt as fine as the thread of a cobweb.

The aſcent of fluids in tubes of this kind is a phenomenon which has been noticed by philoſophers, and of which different accounts have been given. The fact is unqueſtionable; for if one end of a ſmall tube, open at both ends, be immerged in water, the liquor within the tube will riſe to a ſenſible height above the external ſurface; or if two or more tubes be immerged in the ſame fluid, e. g. water, one of them a capillary one, and the other conſiderably larger, the water will riſe perceptibly much higher in the former than in the latter; in the reciprocal ratio of the diameters of the tubes: and the effect is the ſame in vacuo as in the open air.

The greateſt height to which Dr. Hook ever found water to aſcend above the level of the baſon, in his very ſmall capillary tubes, did not exceed 21 inches. See Ascent *of fluids.*

For the illuſtration of this phenomenon, we may obſerve in general, that the particles of water and of other fluids mutually attract each other; and that there is alſo an attraction between glaſs and water, &c. which is increaſed by cold, and diminiſhed by heat, but which is, *cæteris paribus*, proportional to the ſurface of contact. The mutual attraction of particles of water is evinced by the globular forms of the drops of this fluid, by their coaleſcing when brought near one another, and by a variety of other phenomena. It is obſerved alſo, that if we breathe on a glaſs plate, the breath will adhere to it longer in cold, than in hot weather. If a drop of water be laid upon glaſs, the ſurface moſt remote from the glaſs will retain a convex form, whilſt that which touches it will adapt itſelf to the ſurface of the glaſs, and adhere to it with a certain degree of force; but if the ſame drop be ſpread over the ſurface of the glaſs, it will loſe its convex ſurface, and adhere to the glaſs with a greater force.

By this diſperſion of its particles they will be removed farther from each other, and their mutual attraction will be diminiſhed; whereas, on the other hand, the attraction between the water and the glaſs is increaſed by enlarging the ſurface of contact. In either of theſe caſes, the water is attracted by the glaſs only on one ſide; but if another piece of glaſs be placed in oppoſition to the former, and in contact with the film of water, the water will be attracted and retained with a greater force; and if the water be on every ſide encompaſſed with glaſs, or encloſed in a narrow tube, the attraction will become ſtronger, becauſe the ſurface of contact in proportion to the quantity of water is thus conſiderably enlarged. The truth of theſe obſervations may be evinced in the following manner. Put water into a glaſs veſſel, (*Plate* I. *Hydroſtatics*, *fig.* 1.) and the water near the ſurface of the glaſs will aſcend, and form a curve, as at A and B; or the ſame effect will be exhibited at C and D, by dipping part of a piece of glaſs in the water. In order to explain this effect, let A B, (*fig.* 2.) repreſent a ſection of the ſurface of a piece of glaſs, the lower part of which is immerſed in the water, B C: and ſuppoſe this ſurface to be divided into a number of indefinitely ſmall parts, *a*, *b*, *c*, *d*, &c.; then the part *a*, next to the ſurface of the water, B C, will raiſe a quantity of water proportional to its attractive force; which quantity is thus brought nearer to the part *b* of the glaſs, and attracted by it, ſo that another quantity of water takes its place next to *a*. The firſt quantity of water being raiſed to *b*, is brought nearer to the part *c* of the glaſs, and being attracted by it, is raiſed to the place *c*, whilſt the firſt quantity of water *a*, takes its place, which is ſucceeded by another quantity of water which riſes to the place *a*; ſo of the others. In conſequence of this attraction, the water ought to form a film of equal thickneſs, or the quadrilateral figure, *g*, *h*, *a*, *s*, on the whole ſurface of the glaſs. But by reaſon of the mutual attraction of the particles of water towards each other, when the firſt quantity of water has been raiſed to the place *a*, another quantity of water *s*, is kept ſuſpended by this latter attraction, between the water at *a*, and that at B C. When the glaſs has by its attraction raiſed the water to *b*, the part *s* will be extended to *t z*, becauſe the two quantities of water, *a* and *b*, can keep ſuſpended a greater portion of water than the ſingle part *a*. Thus, the water will aſcend along the ſurface of the glaſs, and will remain adhering to it, in ſuch quantity as to form a counterpoiſe to the attraction of the glaſs; or, in other words, the preſſure of the water thus raiſed, and the attraction between it and the water, B C, will form by their united actions a counterpoiſe to the attraction of the glaſs. The real aſcent of the water, which, in the figure we have referred to, has been enlarged for the better illuſtration of the ſubject, ſeldom exceeds $\frac{1}{10}$th of an inch, when the glaſs is either flat, or not much bent. But this altitude is increaſed by a variety of circumſtances; viz. by the temperature and purity of the water, by the quality of the glaſs, and chiefly by the poliſh and cleanlineſs of its ſurface.

In ſmall tubes of different diameters, the perpendicular aſcent of water, and of various other fluids, will be inverſely as their reſpective diameters. Thus, if glaſs tubes opened at both ends be immerſed with their lower apertures in water, (ſee *fig.* 3.) the water will inſtantly riſe ſpontaneouſly into their cavities; and it has been found to riſe higher and with a greater velocity in narrower than in large tubes, according to the proportion in which the diameters of the larger tubes exceed thoſe of the ſmaller; and the altitude in a tube of $\frac{1}{100}$th part of an inch, (viz. 0.01), in diameter, will be about 5.3 inches. Conſequently, in a tube of 0,02 in diameter, the altitude of the water will be the half of 5.3, viz. 2.65 inches. Alſo, in a tube whoſe diameter is 0.1 of an inch, or 10 times 0.01, the altitude of the water will be the 10th part of 5.3, or 0.53 of an inch, &c. Hence it follows, that if we call the diameters of the tubes D, *d*, and the altitudes of the water A, *a*, we ſhall have, $D : d :: a : A$, and $A D = a d$; that is, the product of the diameter by the altitude of the water is always the ſame, or the conſtant quantity 0.053 of an inch; for when the diameter is 0.01 of an inch, the water riſes to the altitude of 5.3 inches; and $5.3 \times 0.01$ is equal to $0.053 = 0.02 \times 2.65 = 0.1 \times 0.53$. If, therefore, you wiſh to know how high the water will riſe in a tube of a given diameter, it is only neceſſary to divide 0.053 by the diameter, and the quotient expreſſes the altitude in inches, very nearly; for allowance muſt be made for difference of temperature, the nature and cleanlineſs of the glaſs, &c. which influence the altitude. Moreover, ſince the ſurface of a cylinder is as the product of the diameter multiplied by the axis, or the altitude, and it has been already ſhown, that in the part of the tube occupied by the water, the product of the diameter by the altitude is a conſtant quantity, the ſurface of the glaſs which is in contact with ſuch a pillar of water, is likewiſe a conſtant quantity.

Mr. Atwood, in his "Analyſis," has given the following method of very accurately determining the diameter of a capillary tube. Put into the tube ſome mercury, whoſe weight in grains is $w$, and let it occupy a length of the tube $l$; then, if 13.6 be the ſpecific gravity of mercury, as it is when in its pureſt ſtate, that of water being 1, the diameter will be $= \sqrt{\frac{w}{l}} \times .01923$. For let $d$ be the diameter, and the contents of the mercury will be $= d^2 l \times .7854$; and as one cubic inch of mercury weighs 3443 grains, we have $1 : 3443 :: d^2 l \times .7854 : w$; hence we ſhall have $d^2 l \times .7854 \times 3443 = w$, and $d^2 = \frac{w}{l} \div .7854 \times 3443 = \frac{w}{l} \div 2704.1322$; and $d = \sqrt{\frac{w}{l}} \div \sqrt{2704.1332} = \sqrt{\frac{w}{l}} \times \frac{1}{\sqrt{2704.1332}} = \sqrt{\frac{w}{l}} \times .01923$.

Several ingenious perſons, who, in examining the phenomena of capillary attraction, have found that the bulks of the ſuſpended pillars of water are not proportional to the ſurfaces of glaſs with which they are in contact, have been embarraſſed in explaining them; and for this purpoſe they have adopted various hypotheſes. Some have ſuppoſed that the unequal preſſure of the air upon the liquor contained in the tube and that in the veſſel is the cauſe of the aſcent in the tube. In order to account for this inequality, ſome have had recourſe to the magnitude of the particles of the air and of the aſcending fluid; others have conceived, that only an inverted cone of air, touching the ſurface of the liquor in the tube with its vertex, and having the upper orifice of its tube for its baſe, could preſs upon the ſurface contiguous to its vertex. Dr. Hook ſuppoſed that part of the preſſure of the air in the tube was taken off by its friction, which he apprehends muſt neceſſarily happen againſt the ſides in ſo narrow a paſſage; and this hypotheſis of Dr. Hook was for a long time very generally received. Thoſe who wiſh to ſee his explication of it may find it in the ſixth Obſervation of his "Micrography," or in Cotes's Hydroſtatical and Pneumatical lectures, *(ubi infra.)* But ſince it has been obſerved, that the ſame aſcent of liquors in capillary tubes occurs in vacuo as in the open air; this hypotheſis of an inequality of preſſure has been relinquiſhed; and the ſolution of the difficulty has been ſought for in the mutual attraction of the particles of fluids and thoſe of glaſs. Mr. Hawkſbee, and others, have recourſe to the attraction of the annuli of the concave ſurface of the tube. Dr. Jurin (Phil. Tranſ. N° 355, and N° 363, or Abr. vol. iv. p. 423, &c.) aſcribed the ſuſpenſion of the water to the attraction of the ſmall annular portion, or periphery of the inſide of the tube, to which the upper ſurface of the water is contiguous and adheres; this being the only part of the tube, from which the water muſt recede upon its ſubſiding, and conſequently, the only one which, by the force of its coheſion and attraction, counteracts the gravity of the water, and oppoſes its deſcent. This he ſhews to be a cauſe proportional to the effect; becauſe the periphery, and the ſuſpended column, are both in the ſame proportion as the diameter of the tube. The ſuſpenſion being thus accounted for, the ſeemingly ſpontaneous aſcent will be eaſily ſolved: for ſince the water that enters the capillary tube, as ſoon as its orifice is dipped in it, has its gravity taken off by the attraction of the periphery, with which its upper ſurface is in contact, it muſt neceſſarily riſe higher; partly by the preſſure of the ſtagnant water, and partly by the attraction of the periphery, immediately above that which is already contiguous to it. Dr. Hamilton, (Lect. ii. p. 47, &c.) diſſatiſfied with the principle adopted by Dr. Jurin and others, ſuppoſes that the pillar of water is ſupported by the attraction of the annulus contiguous to the bottom of the tube. Accordingly, he obſerves, that when the orifice of a ſmall glaſs tube, open at both ends, is dipped in water, the ſmall annular ſurface of glaſs, on the inſide of the tube contiguous to the orifice, will draw up the water lying immediately under it, and every plate of water elevated will raiſe up that lying above it, until the weight of the column raiſed counterbalance the force by which this annulus endeavours to draw up more water. The thin plate of water lying over the loweſt annulus, and every other plate of the elevated water, muſt be attracted upwards and downwards with equal forces, becauſe the attracting ſurfaces above and below it are equal; and therefore the whole column of water, lying above the loweſt annulus, being drawn equally in oppoſite directions, may be conſidered as unaffected by the attraction of the glaſs, and muſt preſs with its whole weight on the water retained at the orifice of the tube by the attraction of that loweſt annulus, which has no other ſurface below it to counteract its force. Moreover, when the water has aſcended into a ſmall glaſs tube, open at both ends, take it up, and wiping off the drop hanging at the end of it, invert the tube: the ſmall column of included water, being drawn equally by the glaſs in oppoſite directions, will deſcend by its own gravity, or ſtop only when it arrives at the loweſt orifice. Or, whilſt the included column is deſcending, let the loweſt orifice be dipped in water, and taken up, and a ſmall plate of water will be retained at its orifice, and then the included column will be quieſcent. Now this column muſt, by means of the intermediate air, preſs with its whole weight upon the plate of water at its orifice, which can be retained by no other force than the attraction of the glaſs annulus, lying juſt within the orifice of the tube. From hence it appears, ſays Dr. Hamilton, that this attraction alone is ſufficient to ſuſtain, and conſequently to raiſe all the water that riſes in glaſs tubes. Againſt this reaſoning Mr. Parkinſon, *(ubi infra)* has alleged the following experiments. 1. Let a cylindrical glaſs tube be divided into very ſmall equal annuli, *a*, *b*, *c*, *d*, *e*, &c. (*fig.* 4.) and *a* being dipped in water, a thin plate of the fluid will be detached from the maſs, which being now in contact with the ſecond annular ſurface *b*, poſſeſſing the ſame power of attraction with *a*, muſt, partly at leaſt, be raiſed by it; and the caſe will be the ſame with the remaining annuli. And if the efforts of the intermediate annuli ſhould be equal and oppoſite, which cannot be allowed, yet the ſuperior annulus at *g*, would be unaffected, and its whole force remain entire, and it muſt contribute, at leaſt, towards the ſupport of the column of water. But that each annulus ſhould exert a force in elevating the lamina of fluid contiguous to it, and not contribute towards the ſupport of the fluid thus elevated, is unaccountable; the power of attraction being inherent in the glaſs, and inſeparable from it. 2. Let the orifice, F, of the compound tube, E D F, (*fig.* 5.) be dipped in water, and it will riſe to an altitude equal to *g b*; and if D F be filled, ſo that the fluid be not in contact with the narrower part, it will ſubſide till its height be equal to *g b*. But let the tube be filled ſo that the fluid be admitted into the narrower part at D, the height of the column ſuſpended will be equal to *a f*, though the loweſt annulus continues the ſame. When this tube is inverted, and the orifice, E, dipped in the fluid, it riſes to an altitude equal to *a f*, if the narrower part of the tube be ſo long; and if E D be leſs than *b g*, it riſes into the wider tube till its height be equal to *b g*, the ſame altitude as if the tubes were cylindrical, and its diameter equal to that of the wider. If theſe experiments be true, it is clear that the water, riſing ſpontaneouſly in glaſs tubes, is neither raiſed nor ſupported by the attraction of the loweſt annulus.

Others have maintained, and this opinion ſeems to be the moſt unexceptionable, that the attraction is proportional to the whole ſurface of the glaſs which is in contact with the column of water; for every point or particle of that ſurface poſſeſſes an equal attractive power; and the preſſure of the ſuſpended water is equivalent to it, or the one is a counterpoiſe to the other. This influence of glaſs, and other ſubſtances, upon fluids is ſcarcely perceptible beyond the immediate points of contact; nevertheleſs, it is clear, that a film of water of a certain thickneſs muſt be within the extent of that attractive power all round the inner ſurface of the tube, as high as the top of the pillar; but the reſt of the water, which fills up the cavity of the tube, is attracted to that film, and is kept ſuſpended by it, in conſequence of the mutual attraction of the particles of water: yet the whole column is kept up by the attraction of the glaſs, and is a counterpoiſe to that force. Let water be kept ſuſpended in the cylindrical glaſs tube, A B C D, (*fig.* 6.); and let the attraction of the glaſs extend to the lines, E G, F H; and circles of the fluid, whoſe breadths are *m n*, *r s*, &c. will adhere to the ſurface, and certainly be ſupported by the immediate attraction of the glaſs, which is ſo great, that water ſuſpended in a capillary tube will not evaporate, though expoſed to the air for ſix or ſeven months: but the intermediate column, E G H F, is only ſupported by the adheſion of the particles of the fluid to theſe circles, and to the higheſt lamina, G H; the attraction of any intermediate lamina, L M, being the ſame both upwards and downwards; and when the weight of this intermediate column exceeds their accumulated force, it muſt deſcend. This ſeems to be certain, that the ſhell of particles, C E F D, is ſuſtained by the intermediate action of the glaſs, which is diffuſed to the intermediate lamina, *n p*, *s t*, &c. by the coheſion of the particles themſelves; and in this manner the forces of the oppoſite points, *m*, *q*, and *r*, *v*, conſpire, which does not obtain in the forces of the particles upon the outſide of the tube; and this ſeems to be the reaſon why a column of the fluid is not elevated

By this diſperſion of its particles they will be removed farther from each other, and their mutual attraction will be diminiſhed; whereas, on the other hand, the attraction between the water and the glaſs is increaſed by enlarging the ſurface of contact. In either of theſe caſes, the water is attracted by the glaſs only on one ſide; but if another piece of glaſs be placed in oppoſition to the former, and in contact with the film of water, the water will be attracted and retained with a greater force; and if the water be on every ſide encompaſſed with glaſs, or encloſed in a narrow tube, the attraction will become ſtronger, becauſe the ſurface of contact in proportion to the quantity of water is thus conſiderably enlarged. The truth of theſe obſervations may be evinced in the following manner. Put water into a glaſs veſſel, (*Plate* I. *Hydroſtatics*, *fig.* 1.) and the water near the ſurface of the glaſs will aſcend, and form a curve, as at A and B; or the ſame effect will be exhibited at C and D, by dipping part of a piece of glaſs in the water. In order to explain this effect, let A B, (*fig.* 2.) repreſent a ſection of the ſurface of a piece of glaſs, the lower part of which is immerſed in the water, B C: and ſuppoſe this ſurface to be divided into a number of indefinitely ſmall parts, *a*, *b*, *c*, *d*, &c.; then the part *a*, next to the ſurface of the water, B C, will raiſe a quantity of water proportional to its attractive force; which quantity is thus brought nearer to the part *b* of the glaſs, and attracted by it, ſo that another quantity of water takes its place next to *a*. The firſt quantity of water being raiſed to *b*, is brought nearer to the part *c* of the glaſs, and being attracted by it, is raiſed to the place *c*, whilſt the firſt quantity of water *a*, takes its place, which is ſucceeded by another quantity of water which riſes to the place *a*; ſo of the others. In conſequence of this attraction, the water ought to form a film of equal thickneſs, or the quadrilateral figure, *g*, *h*, *a*, *s*, on the whole ſurface of the glaſs. But by reaſon of the mutual attraction of the particles of water towards each other, when the firſt quantity of water has been raiſed to the place *a*, another quantity of water *s*, is kept ſuſpended by this latter attraction, between the water at *a*, and that at B C. When the glaſs has by its attraction raiſed the water to *b*, the part *s* will be extended to *t z*, becauſe the two quantities of water, *a* and *b*, can keep ſuſpended a greater portion of water than the ſingle part *a*. Thus, the water will aſcend along the ſurface of the glaſs, and will remain adhering to it, in ſuch quantity as to form a counterpoiſe to the attraction of the glaſs; or, in other words, the preſſure of the water thus raiſed, and the attraction between it and the water, B C, will form by their united actions a counterpoiſe to the attraction of the glaſs. The real aſcent of the water, which, in the figure we have referred to, has been enlarged for the better illuſtration of the ſubject, ſeldom exceeds $\frac{1}{10}$th of an inch, when the glaſs is either flat, or not much bent. But this altitude is increaſed by a variety of circumſtances; viz. by the temperature and purity of the water, by the quality of the glaſs, and chiefly by the poliſh and cleanlineſs of its ſurface.

In ſmall tubes of different diameters, the perpendicular aſcent of water, and of various other fluids, will be inverſely as their reſpective diameters. Thus, if glaſs tubes opened at both ends be immerſed with their lower apertures in water, (ſee *fig.* 3.) the water will inſtantly riſe ſpontaneouſly into their cavities; and it has been found to riſe higher and with a greater velocity in narrower than in large tubes, according to the proportion in which the diameters of the larger tubes exceed thoſe of the ſmaller; and the altitude in a tube of $\frac{1}{100}$th part of an inch, (viz. 0.01), in diameter, will be about 5.3 inches. Conſequently, in a tube of 0,02 in diameter, the altitude of the water will be the half of 5.3, viz. 2.65 inches. Alſo, in a tube whoſe diameter is 0.1 of an inch, or 10 times 0.01, the altitude of the water will be the 10th part of 5.3, or 0.53 of an inch, &c. Hence it follows, that if we call the diameters of the tubes D, *d*, and the altitudes of the water A, *a*, we ſhall have, $D : d :: a : A$, and $A\,D = a\,d$; that is, the product of the diameter by the altitude of the water is always the ſame, or the conſtant quantity 0.053 of an inch; for when the diameter is 0.01 of an inch, the water riſes to the altitude of 5.3 inches; and $5.3 \times 0.01$ is equal to $0.053 = 0.02 \times 2.65 = 0.1 \times 0.53$. If, therefore, you wiſh to know how high the water will riſe in a tube of a given diameter, it is only neceſſary to divide 0.053 by the diameter, and the quotient expreſſes the altitude in inches, very nearly; for allowance muſt be made for difference of temperature, the nature and cleanlineſs of the glaſs, &c. which influence the altitude. Moreover, ſince the ſurface of a cylinder is as the product of the diameter multiplied by the axis, or the altitude, and it has been already ſhown, that in the part of the tube occupied by the water, the product of the diameter by the altitude is a conſtant quantity, the ſurface of the glaſs which is in contact with ſuch a pillar of water, is likewiſe a conſtant quantity.

Mr. Atwood, in his "Analyſis," has given the following method of very accurately determining the diameter of a capillary tube. Put into the tube ſome mercury, whoſe weight in grains is $w$, and let it occupy a length of the tube $l$; then, if 13.6 be the ſpecific gravity of mercury, as it is when in its pureſt ſtate, that of water being 1, the diameter will be $= \sqrt{\frac{w}{l}} \times .01923$. For let $d$ be the diameter, and the contents of the mercury will be $= d^2 l \times .7854$; and as one cubic inch of mercury weighs 3443 grains, we have $1 : 3443 :: d^2 l \times .7854 : w$; hence we ſhall have $d^2 l \times .7854 \times 3443 = w$, and $d^2 = \frac{w}{l} \div .7854 \times 3443 = \frac{w}{l} \div 2704.1322$; and $d = \sqrt{\frac{w}{l}} \div \sqrt{2704.1332} = \sqrt{\frac{w}{l}} \times \frac{1}{\sqrt{2704.1332}} = \sqrt{\frac{w}{l}} \times .01923$.

Several ingenious perſons, who, in examining the phenomena of capillary attraction, have found that the bulks of the ſuſpended pillars of water are not proportional to the ſurfaces of glaſs with which they are in contact, have been embarraſſed in explaining them; and for this purpoſe they have adopted various hypotheſes. Some have ſuppoſed that the unequal preſſure of the air upon the liquor contained in the tube and that in the veſſel is the cauſe of the aſcent in the tube. In order to account for this inequality, ſome have had recourſe to the magnitude of the particles of the air and of the aſcending fluid; others have conceived, that only an inverted cone of air, touching the ſurface of the liquor in the tube with its vertex, and having the upper orifice of its tube for its baſe, could preſs upon the ſurface contiguous to its vertex. Dr. Hook ſuppoſed that part of the preſſure of the air in the tube was taken off by its friction, which he apprehends muſt neceſſarily happen againſt the ſides in ſo narrow a paſſage; and this hypotheſis of Dr. Hook was for a long time very generally received. Thoſe who wiſh to ſee his explication of it may find it in the ſixth Obſervation of his "Micrography," or in Cotes's Hydroſtatical and Pneumatical lectures, *(ubi infra.)* But ſince it has been obſerved, that the ſame aſcent of liquors in capillary tubes occurs in vacuo as in the open air; this hypotheſis of an inequality of preſſure has been relinquiſhed; and the ſolution of the difficulty has been ſought for in the mutual attraction of the particles of fluids and thoſe of glaſs. Mr. Hawkſbee, and others, have recourſe to the attraction of the annuli of the concave ſurface of the tube. Dr. Jurin (Phil. Tranſ. N° 355, and N° 363, or Abr. vol. iv. p. 423, &c.) aſcribed the ſuſpenſion of the water to the attraction of the ſmall annular portion, or periphery of the inſide of the tube, to which the upper ſurface of the water is contiguous and adheres; this being the only part of the tube, from which the water muſt recede upon its ſubſiding, and conſequently, the only one which, by the force of its coheſion and attraction, counteracts the gravity of the water, and oppoſes its deſcent. This he ſhews to be a cauſe proportional to the effect; becauſe the periphery, and the ſuſpended column, are both in the ſame proportion as the diameter of the tube. The ſuſpenſion being thus accounted for, the ſeemingly ſpontaneous aſcent will be eaſily ſolved: for ſince the water that enters the capillary tube, as ſoon as its orifice is dipped in it, has its gravity taken off by the attraction of the periphery, with which its upper ſurface is in contact, it muſt neceſſarily riſe higher; partly by the preſſure of the ſtagnant water, and partly by the attraction of the periphery, immediately above that which is already contiguous to it. Dr. Hamilton, (Lect. ii. p. 47, &c.) diſſatiſfied with the principle adopted by Dr. Jurin and others, ſuppoſes that the pillar of water is ſupported by the attraction of the annulus contiguous to the bottom of the tube. Accordingly, he obſerves, that when the orifice of a ſmall glaſs tube, open at both ends, is dipped in water, the ſmall annular ſurface of glaſs, on the inſide of the tube contiguous to the orifice, will draw up the water lying immediately under it, and every plate of water elevated will raiſe up that lying above it, until the weight of the column raiſed counterbalance the force by which this annulus endeavours to draw up more water. The thin plate of water lying over the loweſt annulus, and every other plate of the elevated water, muſt be attracted upwards and downwards with equal forces, becauſe the attracting ſurfaces above and below it are equal; and therefore the whole column of water, lying above the loweſt annulus, being drawn equally in oppoſite directions, may be conſidered as unaffected by the attraction of the glaſs, and muſt preſs with its whole weight on the water retained at the orifice of the tube by the attraction of that loweſt annulus, which has no other ſurface below it to counteract its force. Moreover, when the water has aſcended into a ſmall glaſs tube, open at both ends, take it up, and wiping off the drop hanging at the end of it, invert the tube: the ſmall column of included water, being drawn equally by the glaſs in oppoſite directions, will deſcend by its own gravity, or ſtop only when it arrives at the loweſt orifice. Or, whilſt the included column is deſcending, let the loweſt orifice be dipped in water, and taken up, and a ſmall plate of water will be retained at its orifice, and then the included column will be quieſcent. Now this column muſt, by means of the intermediate air, preſs with its whole weight upon the plate of water at its orifice, which can be retained by no other force than the attraction of the glaſs annulus, lying juſt within the orifice of the tube. From hence it appears, ſays Dr. Hamilton, that this attraction alone is ſufficient to ſuſtain, and conſequently to raiſe all the water that riſes in glaſs tubes. Againſt this reaſoning Mr. Parkinſon, *(ubi infra)* has alleged the following experiments. 1. Let a cylindrical glaſs tube be divided into very ſmall equal annuli, *a*, *b*, *c*, *d*, *e*, &c. (*fig.* 4.) and *a* being dipped in water, a thin plate of the fluid will be detached from the maſs, which being now in contact with the ſecond annular ſurface *b*, poſſeſſing the ſame power of attraction with *a*, muſt, partly at leaſt, be raiſed by it; and the caſe will be the ſame with the remaining annuli. And if the efforts of the intermediate annuli ſhould be equal and oppoſite, which cannot be allowed, yet the ſuperior annulus at *g*, would be unaffected, and its whole force remain entire, and it muſt contribute, at leaſt, towards the ſupport of the column of water. But that each annulus ſhould exert a force in elevating the lamina of fluid contiguous to it, and not contribute towards the ſupport of the fluid thus elevated, is unaccountable; the power of attraction being inherent in the glaſs, and inſeparable from it. 2. Let the orifice, F, of the compound tube, E D F, (*fig.* 5.) be dipped in water, and it will riſe to an altitude equal to *g b*; and if D F be filled, ſo that the fluid be not in contact with the narrower part, it will ſubſide till its height be equal to *g b*. But let the tube be filled ſo that the fluid be admitted into the narrower part at D, the height of the column ſuſpended will be equal to *a f*, though the loweſt annulus continues the ſame. When this tube is inverted, and the orifice, E, dipped in the fluid, it riſes to an altitude equal to *a f*, if the narrower part of the tube be ſo long; and if E D be leſs than *b g*, it riſes into the wider tube till its height be equal to *b g*, the ſame altitude as if the tubes were cylindrical, and its diameter equal to that of the wider. If theſe experiments be true, it is clear that the water, riſing ſpontaneouſly in glaſs tubes, is neither raiſed nor ſupported by the attraction of the loweſt annulus.

Others have maintained, and this opinion ſeems to be the moſt unexceptionable, that the attraction is proportional to the whole ſurface of the glaſs which is in contact with the column of water; for every point or particle of that ſurface poſſeſſes an equal attractive power; and the preſſure of the ſuſpended water is equivalent to it, or the one is a counterpoiſe to the other. This influence of glaſs, and other ſubſtances, upon fluids is ſcarcely perceptible beyond the immediate points of contact; nevertheleſs, it is clear, that a film of water of a certain thickneſs muſt be within the extent of that attractive power all round the inner ſurface of the tube, as high as the top of the pillar; but the reſt of the water, which fills up the cavity of the tube, is attracted to that film, and is kept ſuſpended by it, in conſequence of the mutual attraction of the particles of water: yet the whole column is kept up by the attraction of the glaſs, and is a counterpoiſe to that force. Let water be kept ſuſpended in the cylindrical glaſs tube, A B C D, (*fig.* 6.); and let the attraction of the glaſs extend to the lines, E G, F H; and circles of the fluid, whoſe breadths are *m n*, *r s*, &c. will adhere to the ſurface, and certainly be ſupported by the immediate attraction of the glaſs, which is ſo great, that water ſuſpended in a capillary tube will not evaporate, though expoſed to the air for ſix or ſeven months: but the intermediate column, E G H F, is only ſupported by the adheſion of the particles of the fluid to theſe circles, and to the higheſt lamina, G H; the attraction of any intermediate lamina, L M, being the ſame both upwards and downwards; and when the weight of this intermediate column exceeds their accumulated force, it muſt deſcend. This ſeems to be certain, that the ſhell of particles, C E F D, is ſuſtained by the intermediate action of the glaſs, which is diffuſed to the intermediate lamina, *n p*, *s t*, &c. by the coheſion of the particles themſelves; and in this manner the forces of the oppoſite points, *m*, *q*, and *r*, *v*, conſpire, which does not obtain in the forces of the particles upon the outſide of the tube; and this ſeems to be the reaſon why a column of the fluid is not elevated upon the outſide, as it is within. Upon the whole it appears, that the preſſure of the column of water in the tube is equivalent, or it is a counterpoiſe, to the attractive force of the ſurface of the glaſs, which is in contact with it; and of courſe it is proportional to that ſurface. But in eſtimating the quantity of that counterpoiſe, or of the preſſure of the column of water, we muſt take into the account not only the quantity, but alſo the altitude; becauſe, *cæteris paribus*, fluids preſs in proportion to their perpendicular altitudes; and when the baſe varies, as in different cylindrical pillars, the preſſures are as the products of the quantity of matter by the altitude of each pillar reſpectively. Therefore the preſſure of the pillar of water in a glaſs tube, which is a counterpoiſe to the attraction of the glaſs, is the product of the quantity of water by the altitude; and in cylindrical tubes, this product is always proportional to the ſurface of glaſs in contact with water. Having already ſhewn, that this ſurface is a conſtant quantity, it follows, that the product of the quantity of water by the altitude of the pillar muſt likewiſe be a conſtant quantity; ſince it is as the abovementioned ſurface. In order to illuſtrate this by an example; let the inſide of the diameter of a tube, B C, (*fig.* 7.) be double that of the tube, D F; then the pillar of water, F E, will be two inches high when the pillar, A C, is one inch high. Since the contents of cylinders of the ſame altitude are as the ſquares of their reſpective diameters, and their ſurfaces are ſimply as their diameters, it is eaſily calculated that if the quantity of water in the pillar, E F, weighs two grains, that of A C muſt weigh four grains; and likewiſe that the ſurface of glaſs in contact with the pillar of water, E F, is equal to the ſurface of glaſs which is in contact with the pillar of water, A C; hence it ſhould ſeem that thoſe equal ſurfaces ought to keep ſuſpended equal quantities of water; whereas the quantity of water, E F, is the half of the quantity of water, A C; but the height of the pillar of water, E F, is double that of the pillar, A C; and conſequently, its preſſure, which is equal to the product of the quantity of water by the altitude (viz. two grains by two inches) is equal to the preſſure of the column, A C, viz. the product of four grains by one inch.

If a tube conſiſt of two cylinders, one E F, (*fig.* 8.) whoſe diameter is equal to that of the tube, A B, in which the water would riſe to the height A B, and the other, a larger part, C D, whoſe diameter is equal to that of the tube, G H, in which the water would riſe to the height G H; and if this compound tube be placed with the narrow aperture in water, as at F, the water will not riſe in it higher than the altitude G H, i. e. to the ſame altitude to which it would riſe if the tube were an uniform cylinder of the diameter of the large part. It might, indeed, be expected, that the water would riſe higher than D, G; but it muſt be conſidered that though the product of the pillar of water, E F, by its altitude is leſs than a juſt counterpoiſe to the attraction of the ſurface, E F, of the glaſs; yet the exceſs of attraction of that ſurface, inſtead of aiding to ſupport the water in C E, will operate in a contrary way: that is, if we ſtate the attraction of the ſurface, E F, equal to 10, and if the preſſure of the pillar of water in it be equal to 8; then the two remaining parts of attractive power will tend to draw the water from the baſon as much as from the cavity, D E, towards the ſurface, E F; ſo that by the addition of the narrow tube, E F, the attraction of the larger part, D I, is diminiſhed; at the ſame time that the water in it is partially ſupported by what may be called its perforated baſe, I E.

If a compound tube conſiſting of a larger part, L N, (*fig.* 8.) in which the water would riſe ſpontaneouſly to the altitude, M, and of a narrower part, O K, equal in diameter to the tube, A B, in which the water would riſe to the height A B, be filled with water as high as K, and then be placed with the large aperture in water as at N, the whole quantity of water will remain ſuſpended, filling the whole of the large tube and part of the narrow one. The ſame thing will alſo take place with a veſſel of any ſhape, as P Q S, provided its upper part be drawn into a narrow cylinder equal in diameter to the tube, A B. In theſe veſſels the water is ſupported partly by the attraction of coheſion, and partly by the preſſure of the atmoſphere. That the preſſure of the atmoſphere contributes in a great degree to this effect is evident, becauſe the water will not riſe ſpontaneouſly into the veſſels, O N, P S, to the heights K and P, and alſo becauſe if theſe veſſels full of water as high as P, K, together with the baſon, be placed under the receiver of an air-pump, on exhauſting the receiver of air or removing the preſſure of the atmoſphere, the water will deſcend in them, and will remain in them only as high as it would aſcend ſpontaneouſly. Mr. Cavallo (*ubi infra*) has illuſtrated the mode by which water is ſupported in theſe veſſels; and for this purpoſe he has calculated, that if the diameter of the aperture, P, be 0.004 of an inch, which will be nearly the caſe when the perpendicular altitude, P Q, of the water is 1 foot, the whole preſſure of the atmoſphere on the ſurface of the water in the tube at P, will be little more than one grain; and as the atmoſphere preſſes upon that ſurface with only the 32d part of its entire force, the perpendicular height of the water in the veſſel, P Q S, being one foot, the actual preſſure of the atmoſphere on the ſurface of the water at P, will be $\frac{4}{100}$dths of a grain nearly. But this trifling preſſure not being ſufficient to overcome the attraction between the water and the ſurface of the tube, P, the water muſt remain ſuſpended in the veſſels, P Q S, or O N. The following experiment corroborates this explanation. Fill the veſſels, O N, or P Q S, up to the height, T, by lowering them in the water of the baſon; and in that ſituation touch the aperture, O, or P, with a wet finger, ſo as to introduce a little water into it. Then if the veſſel be drawn up, leaving its lower aperture only in the water of the baſon, the column of water, T N, or T Q, will remain ſuſpended in it, though there be no communication whatever between the water at T, and the water in the capillary aperture.

The altitudes of water, ſuſpended in compound tubes, vary inverſely as the diameters of the upper orifices nearly. E. G. In open cylindrical tubes, whoſe diameters are equal to thoſe of the different parts, A B, and C, (*fig.* 9.) of the compound tube, A B C, water riſes ſpontaneouſly to altitudes equal to *g r*, and *g s*, which are inverſely as their diameters nearly. Whether the orifice, A or C, be immerſed in the fluid, it riſes to the altitude, *g r*; but if the tube be filled, ſo that the water may be in contact with the narrow part of the tube, C, the whole column will be ſuſpended, if its altitude does not exceed *g s*. Again, let *af*, and *bg*, (*fig* 10.) be the altitudes of water raiſed ſpontaneouſly in the open cylindrical tubes, E D, and D F, reſpectively, which are inverſely as their diameters. When the wider orifice is immerſed, and the tube is filled with water to an altitude leſs than the length of the wider part, it will ſubſide to a level with the point, *g*: but if the water be admitted into the narrower tube, the whole column will be ſuſpended if its length do not exceed *af*. If the tube be inverted, and the narrower orifice immerſed, and water raiſed into the tube, D F, it immediately ſinks, if the altitude of the column exceed *bg*. Let *adc* (*fig.* 11.) be a capillary ſiphon, in whoſe narrower and wider legs, if ſufficiently long, columns of water, whoſe altitudes are *ef*, and *gh*, reſpectively, and which are inverſely as their diameters, may be ſuſpended. Fill this ſiphon with water, and hold it in the poſition of *fig.* 11; and the fluid will not run out of the orifice, *c*, unleſs the difference of the legs, *dc*, exceed *ef*. If the narrower leg be longer than the wider, the water will flow out of the orifice, *c*, (*fig.* 12.) if the leg, *dc*, exceed *gh*.

Capillary tubes which naturally diſcharge water only in ſeparate drops, yield, when electrified, a continued and accelerated ſtream; and the acceleration is proportional to the ſmallneſs of the tube: and the effect of electricity is ſo conſiderable, that it produces a continued ſtream from a very ſmall tube, out of which the water had not before been able to drop. Prieſtley's Hiſt. Electr. 8vo. vol. i. p. 171. ed. 3d.

In connection with the preceding account of capillary tubes we ſhall here introduce that of contiguous glaſs plates, between which water riſes according to the ſame law with that of ſuch tubes, or in ſuch a manner that the altitudes are inverſely as the diſtances of the plates. E. G. If the glaſs plates be parallel to each other and placed with their lower edges in water, the water will riſe between them, and will remain ſuſpended at a certain height. This height is not ſo great as that of the water in a glaſs tube, whoſe diameter is equal to the diſtance between the two plates, for an obvious reaſon; becauſe the water in the tube is ſurrounded on every ſide by glaſs: nevertheleſs the proportion is the ſame; i. e. in two or more pairs of glaſs plates, the altitudes of the water are inverſely as the diſtances of the plates, and the cauſe of the aſcent is the ſame as in glaſs tubes. A C D F and B C D E, (*fig.* 13.) repreſent two flat glaſs plates, placed ſo as to form a ſmall angle, A C B, and immerſed with their lower edges in water. The water will riſe between them, and remain ſuſpended in the ſpace E F C D E, the outer edge of which, E F C, being a curve called an "hyperbola." One extremity of this curve riſes as high as the upper part of the glaſs plates at C, and the other extremity reaches as far as the edges of the glaſſes contiguous to the water of the baſon at F and E. The water between theſe plates riſes higher near the ſide, C D; and lower at a diſtance from it. In ſhort, at any diſtance from C D, as at *ab*, *cd*, *ef*, the water riſes as high as it would riſe between parallel plates, whoſe diſtance from each other equalled the diſtance between the plates of *fig.* 15, at any of thoſe particular places. Conſequently the altitudes of the water at different diſtances from C D, are inverſely as the diſtances between the two plates at thoſe places. In *fig.* 14, which exhibits the ſame elevation of water with that which is repreſented in *fig.* 13, any two, or more, altitudes of water, as *ab* and *cd*, are inverſely as the diſtances *bt*, *di*, between the two plates at thoſe places; viz. $ab : cd :: di : bt ::$ (by the ſimilarity of the triangles D *bt*, D *di*) D *d* : D *b*; and this is the known property of the common hyperbola, whoſe aſymptotes are the edge, C D, of the glaſſes, and the line, D S, where the glaſs plate interſects the ſurface of the water in the veſſel, G. The water muſt evidently riſe as high as the apex, C, whatever be the altitude of the plates, ſince the glaſs plates come infinitely near each other near the edge, C D. If theſe plates were bent more or leſs, then the edge of the water which riſes between them would not be an hyperbola, but vary according to the curvature of the plates. Let two flat glaſs plates be diſpoſed, as in *fig.* 15, ſo as to form a ſmall angle with each other, as in the former caſe; and the lowermoſt of theſe be ſo placed as to form a ſmall angle with the horizon, having the edge, B, a little elevated. Let them be ſeparated at E C by the interpoſition of ſome thin body, and previouſly moiſtened with water; and if a drop of water be introduced between theſe plates at E C, ſo as to touch them both, it will move ſpontaneouſly towards the upper part of the plates, as far as the edge, A B. The drop of water moves towards the edge, A B, even againſt the direction of its gravity; becauſe the attraction of the glaſſes towards the drop is ſtronger where the plates are cloſer to each other, as at *d*, than where they are further aſunder, as at *e*; ſo that the drop at *o*, is more powerfully attracted towards *d*, than towards *e*. If the ſide, A B, be gradually raiſed higher and higher above the horizon, whilſt the drop is moving, it will be perceived to move ſlower and ſlower towards A B, until at laſt the gravity of the drop balances the attraction of the glaſſes, and the water remains at reſt. After which, if the edge, A B, be raiſed ſtill higher, the weight of the drop being greater than the attraction of the glaſs, will cauſe it to deſcend towards C E.

Phenomena of attraction, ſimilar to thoſe already illuſtrated in the caſe of glaſs and water, take place between almoſt every fluid and every ſolid; even between fluids and ſolids, or ſolids and ſolids. However, a conſiderable difference reſults from the different degrees of force with which the particles of each body attract either one another, or thoſe of another body. The attraction of water to glaſs is greater than the mutual attraction of its own particles; it is alſo greater than that of any other fluid towards glaſs, not excepting even ſpirituous liquors, which are ſpecifically lighter than water; and hence it is, that water riſes higher in capillary tubes than any other liquor. Muſchenbroek, Martin, and other writers have given tables of the heights to which different fluids aſcend in capillary tubes. It is owing to this capillary attraction, that water riſes through the fine veſſels of wood, and aſcends to the tops of the higheſt trees; that it inſinuates itſelf through the pores of certain ſtones, through ſand, ſugar, ſalt, &c. and that in damp weather, when the air depoſits a conſiderable quantity of water, wood, glue, ropes, linen, paper, parchment, ſalts, &c. imbibe the water, and are thereby ſwelled, moiſtened, ſoftened, and ſome of them actually diſſolved. Hence it is that metals in a fluid ſtate riſe and ſpread themſelves between the contiguous ſurfaces of other metals that are in a ſolid ſtate; and this is the foundation of the art of ſoldering metals. Hence alſo mercury inſinuates itſelf through the pores of gold and tin; for the particles of mercury attract one another much leſs than they do thoſe of gold or tin. See Ascent of Fluids. See alſo Adhesion and Cohesion.

If glaſs be applied to any other fluid, whoſe particles attract each other more ſtrongly than glaſs attracts them, all the phenomena of ſuch a fluid in capillary tubes, and between glaſs plates, will be the reverſe of thoſe pertaining to water. Quickſilver is ſuch a fluid; and, therefore, if a ſmall globule of quickſilver be laid upon clean paper, and a piece of glaſs be brought into contact with it, the mercury will adhere to it, and will be drawn away from the paper: but if, whilſt the ſmall globule of quickſilver is thus adhering to the glaſs, a large quantity of the ſame fluid be brought in contact with the ſmall globule, the latter will immediately diſengage itſelf from the glaſs, and incorporate with the other maſs. We here perceive that a greater degree of attraction ſubſiſts between the particles of mercury than between them and glaſs, ſo that it is impoſſible to ſpread quickſilver, like water, over the ſurface of glaſs. If quickſilver be put in a glaſs, and any wooden or earthen veſſel, more than an inch in width, the ſurface of the quickſilver will be horizontal towards the middle, but convex towards the ſide. If an iron ball be laid upon quickſilver, a depreſſion of the quickſilver will be obſerved all round the ball. If two ſuch balls be placed upon quickſilver, not very far aſunder, they will run towards each other; becauſe, where the cavities or depreſſions of the quickſilver are joined either between the ball and the ſide of the veſſel, or between the two balls, there the preſſure of the quickſilver upon the ball, or balls, is diminiſhed by the attraction of the quickſilver below ; and of courſe the balls are impelled that way by the ſuperior preſſure on the oppoſite ſides. If a ſmall tube, (*fig.* 16) open at both ends, be partly immerſed in mercury, the mercury will be found to ſtand lower within the tube than in the veſſel ; and this depreſſion has been found to be inverſely as the diameters of the tubes. Thus, if two tubes are immerſed in quickſilver, and the diameter of one is double that of the other, then the difference of perpendicular altitudes between the ſurface of the quickſilver in the latter tube and in the baſon, will be double to the like difference with the former tube. As quickſilver is an opake body, it will be neceſſary to hold the tube A B near the ſide of the veſſel, which is ſuppoſed to be of glaſs, in order to render the depreſſion of the quickſilver within the tube perceptible. The ſame thing takes place between parallel glaſs plates. If they be immerſed in quickſilver, this fluid will ſtand lower between them than in the other part of the veſſel ; and the depreſſion is likewiſe as the diſtances between the plates. If the plates be ſituated ſo as to form a ſmall angle, the quickſilver, riſing leſs near the angular edge than at a diſtance from it, will form a curve, which is an hyperbola, whoſe aſymptotes are the perpendicular edge, or line of the junction of the glaſſes, and the level of the mercury in the baſon. If a glaſs plate be laid in an horizontal ſituation, with a pretty large drop of quickſilver near one edge of it, as in *fig.* 17, which repreſents a ſection of it, and another glaſs plate, A B, be laid ſo as to form a ſmall angle with it, and at the ſame time to compreſs the drop of quickſilver, the latter will move ſpontaneouſly towards O, *i. e.* towards the aperture of the angle, in order to recover its globular figure. If a tube open at both ends, but having its lower end drawn out into a fine capillary aperture, be filled with quickſilver to the altitude of about an inch or two, no mercury will eſcape from the lower aperture ; but if this lower extremity be ſuffered to touch other mercury, or if, by breaking off part of the ſmall end, the aperture be enlarged, the quickſilver will readily run out. For other particulars relating to this ſubject ; ſee the articles to which we have already referred. Muſchenbroek, Introd. at Phil. Nat. tom. i. c. 20. Graveſand. l. i. c. 5. Helſham, Lect. i. ii. Cotes's Hydroſt. &c. Lectures, lect xi. Newt. Opt. p. 380. Hamilton's Lect. ii. Deſaguliers Courſe of Exp. Phil. vol. i. p. 10. p. 37, &c. Martin's Phil. Brit. vol. i. p. 24, &c. Parkinſon's Syſt. of Mechanics and Hydroſtatics, ch. v. Cavallo's Elem. of Nat. or Exp. Phil. vol. ii. ch. 5.

CAPILLARY *veſſels*, in *Anatomy*, the moſt minute and ſubtle ramifications of the veſſels of animal bodies. Many ſmall veſſels of animal bodies have been diſcovered by the modern invention of injecting the veſſels of animals with a coloured fluid, which upon cooling grows hard. See INJECTION.

CAPILLARY *worms*, in children, are the ſame with what are otherwiſe called *crinones*, *comedones*, and *dracunculi*.

CAPILLATION, or CAPILLARY *fracture*, according to ſome writers, is a fracture in the ſkull, ſo ſmall that it can ſcarcely be perceived ; but yet it often proves mortal. See FRACTURE.

CAPILLITIUM VENERIS, in *Phyſiology*, denotes a meteor appearing in the air, in form of fine threads reſembling a ſpider's web.

Some think that the capillitium Veneris derives its origin from a cloud, the watery parts of which having been exhaled by the ſun's heat, only the earthy and ſulphureous parts are left behind, which ſhoot into this figure. It is ſometimes alſo found hanging about woods and coppices, or even extended on the ground like a fine net, frequently enough miſtaken for ſpiders' webs.

CAPILLUS. See HAIR.

CAPILLUS *Veneris*, in *Botany*, See ADIANTUM CAPILLUS VENERIS

CAPILUPI, LELIO, CAMILLO, IPPOLITO, and JULIO, in *Biography*, natives of Mantua and diſtinguiſhed as modern Latin poets. *Lelio*, who is ſaid to have died in his native place in 1560, at the age of 62 years, excelled in the compoſition of centos, and applied ſome of the verſes of Virgil to a deſcription of the modes of life in monaſteries, and of the venereal diſeaſe. *Camillo* wrote a book entitled "the Stratagem," in which he gives an account of the maſſacre at Paris on St. Bartholomew's day : he was not only diſtinguiſhed as a poet, but employed in ſeveral embaſſies. He died in 1548. *Ippolito*, the third brother, was born in 1511, occupied ſeveral poſts of dignity, and whilſt he was firſt ſecretary and miniſter at Rome of cardinal Hercules and D. Ferrante Gozanga, wrote letters to both, ſeveral of which are extant. The moſt intereſting are thoſe that relate to the war of Parma and Mirandola carried on by pope Julius III. and they diſplay much ſkill in negociation and great zeal in the ſervice of his maſter. In 1560 he was promoted to the biſhopric of Fano by Pius IV. and in the following year deputed as his nuncio to Venice. He died at Rome in 1580. *Julio*, the nephew of the former, is ſaid to have ſurpaſſed his uncle Lelio in the compoſition of centos. Some have ſaid that Ippolito excelled in ſatirical poetry ; but others affirm that he, as well as Julio and Camillo, excelled in the elegiac. The "Virgilian cento of the lives of Monks" was printed at Baſil in 1556 ; and Meibomius publiſhed "Julii et Lælii Capiluporum patrum Centones Virgiliani, &c." at Helmſtadt, in 4to. 1600. The "Carmina eorundem," appeared at Rome, 4to. 1527. The poems of the other brothers are printed in the firſt volume of the Deliciæ Poetarum Italorum. Gen. Dict. Tiraboſchi.

CAPINERO, in *Ornithology*, one of the ſynonyms of MOTACILLA ATRICAPILLA, being the name aſſigned it by Olina.

CAPIPLENIUM, from *caput*, *head*, and *plenus*, *full*, is uſed by ſome authors for a catarrh ; but more properly, by the Italian phyſicians, for a continual heavineſs of the head, frequent at Rome, and almoſt endemic.

CAPIRO, in *Geography*, a mountain of South America, being one of thoſe that ſurround the harbour of Porto Bello, ſtands at the utmoſt extremity of the harbour in the road to Panama. Its top is always covered with clouds of a denſity and darkneſs ſeldom ſeen in thoſe of this atmoſphere ; and from theſe, which are called the "Capillo," or cap, has poſſibly been corruptly formed the name of Monte Capiro. When theſe clouds thicken, increaſe in blackneſs, and ſink below their uſual ſtation, it is a ſure ſign of a tempeſt. Whereas on the other hand, their clearneſs and aſcent as certainly indicate the approach of fair weather. Theſe changes are very frequent and very ſudden ; and the ſummit of the mountain is ſeldom obſerved free from clouds. Hence Capiro is regarded as the barometer of the country, by foretelling every change of weather.

CAPISCOLUS, or CAPISCHOLUS, in *Eccleſiaſtical Writers*, denotes a dignitary in certain cathedrals, who had the ſuperintendency of the choir, or band of muſic, anſwering to what in other churches is called *chanter* or *precentor*. The word is alſo written *cabiſcolus*, and *caputſcholæ*, q. d. the *head of the ſchool* or *band of muſic*. The capiſcolus is alſo called *ſcolaſticus*, as having the inſtruction of the young clerks and choriſters, how to perform their duty.

CAPISSA, in *Ancient Geography*, a country of Aſia, in Paropamiſus, mentioned by Ptolemy and Pliny. The latter alſo mentions a town in this country, which was deſtroyed by Cyrus.

CAPISTRAN, John, in *Biography*, a Franciſcan friar, was born at Capiſtran in Naples, in 1385; and having firſt ſtudied the law at Perugia, he relinquiſhed this profeſſion and entered into the order of St. Francis, in 1415. In this connection he roſe, by the auſterity of his manners, as well as by his zeal and eloquence, to the principal offices of his order. As he was ardently attached to the papal authority, he was employed in ſeveral important ſervices by pope Eugenius IV.; and Nicholas V. ſent him into Bohemia to convert the Huſſites and the Jews; of the latter he cauſed many to be burnt in Sileſia, under a pretence of their behaving irreverently towards the conſecrated bread. He was alſo employed to preach a cruſade againſt the Turks, in Germany, Hungary, and Poland; and he contributed by his eloquence to aſſemble the army, which, under the command of the famous Huniades, raiſed the ſiege of Belgrade, in 1456. Capiſtran, in his letter to the pope and the emperor, arrogates to himſelf the honour of this victory. Huniades, on the other hand, takes no notice of Capiſtran, who died within three months after the battle of Belgrade, and was buried in the convent of Willak, in Hungary. Miracles are ſaid to be wrought at his tomb. He was canonized by pope Alexander VIII. in 1690, after having been beatified by Gregory XV. His principal works were "Speculum Clericorum;" "De Poteſtate Papæ et Conſilii;" "De Pœnis Inferni et Purgatorii;" a treatiſe againſt the Huſſites; and ſome pieces on the civil and canon law. Gen. Dict. Tiraboſchi.

Capistran, in *Geography*, a ſmall place, with a principality, of Naples, in the province of Abruzzo Ultra.

CAPISTRATUS, in *Ichthyology*, a ſpecies of Chætodon, with entire tail; twelve ſpines in the dorſal fin; body ſtriated; and an ocellated ſpot near the tail.

This fiſh has the head rather large, with eyes of conſiderable ſize; a black ocular band with white margin; fins yellowiſh, with branched rays; dorſal and anal fin bordered with brown; and a black band near the caudal fin.

CAPISTRUM, *Lat.* a bandage uſed by performers on trumpets and other wind inſtruments among the ancients, to keep the cheeks and lips firm, and to prevent the diſtortion of the countenance. It was called φορβεια, or περιστομιον, by the Greeks, and is ſuppoſed to have been invented by Marſyas. It is mentioned in Plutarch's Sympoſiacs, in the Scholiaſt of Ariſtophanes, and elſewhere, and may be ſeen in ſome ancient ſculpture which Bartholinus has had engraved in his treatiſe "De Tibiis Veterum."

Capistrum, in *Surgery*, a head-ſtall, or bandage uſed in caſe of injuries of the head, eſpecially fractures of the jaw.

CAPITA, or Capitum, in *Antiquity*, denotes a tax among the Romans for the maintenance of the horſes in the army, levied according to the number of heads thereof.

Capita, *diſtribution by*, in the *Civil Law*, is ſuch a diſtribution, that every man has an equal ſhare of *perſonal* eſtate, when all the claimants claim in their own rights, as in equal degree of kindred, and not *jure repreſentationis*, in the right of another perſon. This mode of diſtribution is contradiſtinguiſhed from a diſtribution *per ſtirpes*, which is the only rule of ſucceſſion according to the common law. Thus, if the next of kin be the inteſtate's three brothers, A, B, and C; here his effects are divided into three equal portions, and diſtributed *per capita*, one to each: but if one of theſe brothers, A, had been dead, leaving three children, and another, B, leaving two; then the diſtribution muſt have been *per ſtirpes*; viz. one-third to A's three children; another third to B's two children; and the remaining third to C, the ſurviving brother: yet, if C had been alſo dead, without iſſue, then A's and B's five children, being all in equal degree to the inteſtate, would take in their own rights *per capita*; viz. each of them one-fifth part. Blackſt. Com. vol. ii p. 517.

Capita, *ſucceſſion by*, is that where the claimants are next in degree to the anceſtor, in their own right, and not by right of repreſentation. Thus, if the next heirs of Titius be ſix nieces, three by one ſiſter, two by another, and one by a third; his inheritance by the Roman law was divided into ſix parts, and one part given to each of the nieces: whereas the law of England in this caſe would ſtill divide it only into three parts, and diſtribute it *per ſtirpes*, thus; one-third to the three children who repreſent one ſiſter, another third to the two who repreſent the ſecond, and the remaining third to the one child who is the ſole repreſentative of her mother. Blackſt. Com. vol. ii. p. 218.

CAPITAL, of the Latin *caput*, is uſed on various occaſions to expreſs the relation of a head, chief, or principal: thus,

Capital *City*, intimates the principal city of a kingdom, province, or ſtate; as London is the capital, or capital city of England; Moſcow, of Ruſſia; Conſtantinople, of the Ottoman empire; &c. See City and Metropolis.

M. Bayle has a diſcourſe on the advantages of being born and living in the capital of the country.

Capital *Court*, *capitalis curia*, the chief manor-houſe, or place-houſe where the lord of the manor holds his court; called alſo in Kent the court-lodge. See Court.

Capital-court is ſometimes uſed for the ſame with capital meſſuage, which ſee.

Capital *Crime*, is that which ſubjects the criminal to a capital puniſhment, i. e. to the loſs of life. See Crime and Punishment.

Capital *Honour*, *capitalis honor*, denotes the chief honour, or prime barony of the whole county, as that in ancient times uſually enjoyed by the count or earl of ſuch county.

Capital *Letters*. See Capitals.

Capital *Lord*, *capitalis dominus*, the lord of the fee, from whom the eſtate is held by inferior tenants.

Capital *Picture*, in *Painting*, denotes one of the moſt excellent pieces of any celebrated maſter.

Capital, or Capital *Stock*, in *Commerce*, is the fund, or ſtock, of a trading company, or corporation; or the ſum of money which they jointly furniſh, or contribute, to be employed in trade. It is alſo uſed to denote the ſtock which a merchant or tradeſman employs in buſineſs on his own account; or the ſum of money which an individual advances towards making up the trading ſtock of a partnerſhip when it is firſt formed. If we extend our views to ſociety at large; the term ſtock is uſed in a greater latitude; and the whole ſtock which a man poſſeſſes may be diſtinguiſhed into two parts; viz. that which is to afford him a revenue, and which is called his capital; and that which ſupplies his immediate conſumption. See Stock. A capital may be employed ſo as to yield a revenue or profit to its employer in two different ways, and accordingly acquires two diſtinct denominations. The capital, employed in raiſing, manufacturing, or purchaſing goods, and ſelling them again with a profit, may properly be called a circulating capital; becauſe it yields no revenue or profit, while the employer retains it in his own poſſeſſion, and whilſt it continues in the ſame ſhape; it is by means of circulation, or ſucceſſive exchanges, that it yields any profit.

But if a capital be employed in the improvement of land, in the purchaſe of uſeful machines and inſtruments of trade, or in ſimilar things which yield a profit without changing maſters, or circulating any farther; this kind of capital may be called a fixed capital. Every fixed capital is originally derived from, and requires to be continually ſupported by a circulating capital: nor can the former yield any revenue but by means of the latter. The circulating capital alſo in its turn requires freſh ſupplies, without which it would ſoon ceaſe to exiſt; and theſe ſupplies are principally drawn from three ſources, viz. the produce of land, that of mines, and that of fiſheries: the cultivation of which requires both a fixed and a circulating capital, and yields a profit, when their natural fertility is equal, proportional to the extent and proper application of the capitals employed about them; or, if the capitals are equal, and equally well applied, proportional to their natural fertility. The intention of the fixed capital is to increaſe the productive powers of labour, or to enable the ſame number of labourers to perform a much greater quantity of work. In a great country, the expence of maintaining a fixed capital may be compared to that of repairs in a private eſtate; and is thus neceſſarily excluded from the neat revenue of the ſociety. But the caſe is different with reſpect to that which maintains the circulating capital. Of the four parts of which this latter capital is compoſed, viz. money, proviſions, materials, and finiſhed work, the three laſt are regularly withdrawn from it, and placed either in the fixed capital of the ſociety, or in their ſtock reſerved for immediate conſumption. Whatever portion of theſe conſumable goods is not employed in maintaining the former, goes altogether to the latter, and forms a part of the neat revenue of the ſociety. In this reſpect the circulating capital of a ſociety is different from that of an individual; the latter is totally excluded from making any part of his neat revenue, which muſt conſiſt wholly in his profits. But though the circulating capital of every individual makes a part of that of the ſociety to which he belongs, it is not on that account totally excluded from making a part likewiſe of their neat revenue. Although the whole goods in a merchant's warehouſe or ſhop muſt by no means be placed in his own ſtock, reſerved for immediate conſumption, they may be ſo placed in that of other people, who, from a revenue derived from other funds, may regularly replace their value to him, together with its profits, without occaſioning any diminution either of his capital or of theirs. Money, therefore, is the only part of the circulating capital of a ſociety, of which the maintenance can occaſion any diminution in their neat revenue. The fixed capital, and that part of the circulating capital which conſiſts in money, ſo far as they affect the revenue of the ſociety, bear a very great reſemblance to one another. See MONEY. When we compare the quantity of induſtry which the circulating capital of any ſociety can employ, we muſt always have regard to thoſe parts of it only, which conſiſt in proviſions, materials, and finiſhed work: the other, which conſiſts in money, and which ſerves only to circulate thoſe three, muſt always be deducted. Money may be requiſite for purchaſing the materials and tools of the work, as well as the maintenance of the workmen. But the quantity of induſtry which the whole capital can employ, is certainly not equal both to the money which purchaſes, and to the materials, tools, and maintenance, which are purchaſed with it; but only to one or other of theſe two values, and to the latter more properly than to the former. Smith's Wealth of Nations, vol. i. For the extenſion of capitals by the aid of banks and paper-credit; ſee BANK and PAPER-MONEY.

CAPITAL, in *Money Matters*, denotes the ſum of money put out to intereſt. In which ſenſe it amounts to the ſame with *principal*, and ſtands oppoſed to *intereſt*. The borrower may uſe it either as a capital, yielding a certain annual rent to the lender, or as a ſtock reſerved for immediate conſumption. If he uſes it as a capital, he employs it in the maintenance of productive labourers, who reproduce the value with a profit; in which caſe he will be able both to reſtore the capital and pay the intereſt without alienating or encroaching upon any other ſource of revenue. But if he uſes it as a ſtock reſerved for immediate conſumption, he acts the part of a prodigal, and diſſipates in the maintenance of the idle, what was deſtined for the ſupport of the induſtrious; and in this caſe, he can never reſtore the capital nor pay the intereſt, without either alienating or encroaching upon ſome other ſource of revenue, ſuch as the property or the rent of land. What the borrower in either of theſe ways really wants, and what the lender readily ſupplies him with, is not the money, but the money's worth, or the goods which it can purchaſe. If he wants it as ſtock for immediate conſumption, it is thoſe goods only which he can place in that ſtock. If he wants it as a capital for employing induſtry, it is from thoſe goods only that the induſtrious can be furniſhed with the tools, materials, and maintenance, neceſſary for carrying on their work. By means of the loan the lender, as it were, aſſigns to the borrower his right to a certain portion of the annual produce of the land and labour of the country, to be employed as the borrower pleaſes. It is the value of that part of the annual produce, which, as ſoon as it comes from the ground, or from the hands of the productive labourers, is deſtined not only for replacing a capital, but ſuch a capital as the owner does not care to be at the trouble of employing himſelf, that regulates the quantity of ſtock, or of money, which can be lent at intereſt in any country. As ſuch capitals are commonly lent out and paid back in money, they conſtitute what is called the *monied intereſt*; which ſee.

Theſe capitals may be greater in almoſt any proportion than the amount of the money which ſerves as the inſtrument of their conveyance; the ſame pieces of money ſucceſſively ſerving for many different loans, as well as for many different purchaſes. Hence, a capital lent at intereſt may, in this manner, be conſidered as an aſſignment from the lender to the borrower of a certain conſiderable portion of the annual produce; upon condition that the borrower in return ſhall, during the continuance of the loan, annually aſſign to the lender a ſmaller portion, called the intereſt; and at the end of it, a portion equally conſiderable with that which had been originally aſſigned to him, called the repayment. In proportion as the ſhare of the annual produce which, as ſoon as it comes either from the ground, or from the hands of the productive labourers, is deſtined for replacing a capital, increaſes in any country, what is called the "Monied Intereſt" naturally increaſes with it. The increaſe of thoſe particular capitals from which the owners wiſh to derive a revenue, without being at the trouble of employing them themſelves, naturally accompanies the general increaſe of capitals; or, in other words, as ſtock increaſes, the quantity of ſtock to be lent at intereſt grows gradually greater and greater. As capitals increaſe in any country, the profits which can be made by employing them neceſſarily diminiſh; and it becomes gradually more and more difficult to find within the country a profitable method of employing any new capital. In conſequence of this there ariſes a competition between different capitals; the owner of one endeavouring to get poſſeſſion of that employment which is occupied by another. The demand for productive labour, by the increaſe of the funds which are deſtined for maintaining it, grows every day greater and greater; ſo that labourers eaſily find employment, whilſt the owners of capitals find it difficult to get labourers to employ. This competition raiſes the wages of labour, and ſinks the profits of ſtock. But when the profits which can be made by the uſe of a capital are thus diminiſhed, as it were, at both ends, the price which can be paid for the uſe of it, that is, the rate of intereſt, muſt neceſſarily be diminiſhed with them. See INTEREST.

All capitals are deſtined for the maintenance of productive labour only; and yet the quantity of ſuch labour, produced by equal capitals, varies very much according to the diverſity of their employment; which is alſo the caſe with reſpect to the value added by that employment to the annual produce of the land and labour of the country.

A capital may be employed in four different ways; either, *firſt*, in procuring the rude produce annually required for the uſe and conſumption of the ſociety; or, *ſecondly*, in manufacturing and preparing that rude produce for immediate uſe and conſumption; or, *thirdly*, in tranſporting either the rude or manufactured produce from the places where they abound to thoſe where they are wanted; or, *laſtly*, in dividing particular portions of either into ſuch ſmall parcels as ſuit the occaſional demands of thoſe who want them. In the firſt of theſe ways are employed the capitals of all thoſe who undertake the improvement or cultivation of lands, mines, or fiſheries: in the ſecond, thoſe of all maſter manufacturers; in the third, thoſe of all wholeſale merchants; and in the fourth, thoſe of all retailers. Each of theſe methods of employing a capital is eſſentially neceſſary either to the exiſtence or extenſion of the other three, or to the general conveniency of the ſociety. The perſons whoſe capitals are employed in any of theſe four ways are themſelves productive labourers. Equal capitals, however, thus employed, put into motion very different quantities of productive labour, and augment alſo in very different proportions the value of the annual produce of the land and labour of the ſociety to which they belong. But no equal capital puts into motion a greater quantity of productive labour than that of the farmer; and, of courſe, the capital employed in agriculture adds a much greater value to the annual produce of the land and labour of the country, and to the real wealth and revenue of its inhabitants. Conſequently, of all the ways in which a capital can be employed, this is by far the moſt advantageous to the ſociety. The capitals employed in the agriculture and in the retail trade of any community muſt always reſide within that community. Whereas the capital of a wholeſale merchant ſeems to have no fixed or neceſſary reſidence any where, but may wander about from place to place, according as it can either buy cheap or ſell dear. The capital of the manufacturer muſt reſide where the manufacture is carried on; but where this ſhall be is not always neceſſarily determined. It may frequently be at a great diſtance from the place where the materials grow, and from that where the complete manufacture is conſumed. Thus, part of the wool of Spain is manufactured in Great Britain, and ſome part of that cloth is afterwards ſent back to Spain. The ſame obſervation applies to the cotton manufacture. Whether the merchant whoſe capital exports the ſurplus produce of any ſociety be a native or a foreigner, is of very little importance; but it is of greater conſequence, that the capital of the manufacturer ſhould reſide within the country. It may, however, be very uſeful to the country, though it ſhould not reſide within it. The capitals of the Britiſh manufacturers, who work up the hemp and flax annually imported from the coaſts of the Baltic, are without doubt very uſeful to the countries which produce them. The merchants who export the commodities wanted in theſe countries, in exchange for theſe materials, replace the capitals of the people who produce them, and thus encourage them to continue the production; and the Britiſh manufacturers replace the capitals of thoſe merchants.

When the capital of any country is not ſufficient for all the three purpoſes now recited, in proportion as a greater ſhare of it is employed in agriculture, the greater will be the quantity of productive labour which it puts into motion within the country, and alſo the value which its employment adds to the annual produce of the land and labour of the ſociety. After agriculture, the capital employed in manufactures puts into motion the greateſt quantity of productive labour, and adds the greateſt value to the annual produce. That which is employed in the trade of exportation has the leaſt effect of any of the three. The country, which has not capital ſufficient for all theſe three purpoſes, has not arrived at that degree of opulence for which it ſeems naturally deſtined. But an attempt to accompliſh all theſe three, prematurely, and with an inſufficient capital, is certainly not the ſhorteſt way for a ſociety, any more than for an individual, to acquire a ſufficient one. The capital of all the individuals of a nation has its limits like that of a ſingle individual, and is capable of executing only certain purpoſes; and it is increaſed by their continually accumulating and adding to it whatever may be ſaved out of their revenue: and the revenue of all the inhabitants of the country is neceſſarily in proportion to the value of the annual produce of their land and labour. The courſe of human proſperity, indeed, ſeems ſcarcely ever to have continued ſo long as to enable any great country to acquire capital ſufficient for all theſe three purpoſes; unleſs, perhaps, we give credit to the wonderful accounts of the wealth and cultivation of China, of thoſe of ancient Egypt, and of the ancient ſtate of Hindooſtan. Theſe three countries have been chiefly renowned for their ſuperiority in agriculture and manufactures; nor do they appear to have been eminent for foreign trade. The greater part of the ſurplus produce of all theſe countries ſeems to have been always exported by foreigners, who give in exchange for it ſomething elſe for which they found a demand there, frequently gold and ſilver. It is thus that the ſame capital will in any country put into motion a greater or ſmaller quantity of productive labour, and add a greater or ſmaller value to the annual produce of its land and labour, according to the different proportions in which it is employed in agriculture, manufactures, and wholeſale trade. See TRADE. The conſideration of his own profit is the ſole motive which determines the owner of any capital to employ it either in agriculture, in manufactures, or in ſome particular branch of the wholeſale or retail trade; and, therefore, in countries, where agriculture is the moſt profitable of all employments, the capitals of individuals will naturally be employed in the manner moſt advantageous to the whole ſociety. The profits of agriculture, however, ſeem to have no ſuperiority over thoſe of other employments in any part of Europe; inſomuch that it would be difficult to produce a ſingle inſtance, in which a large fortune has been acquired by agriculture, in the ſame time and from the ſame capital, which have yielded ſuch a fortune by trade and manufactures, in the whole of Europe during the preſent century; and therefore agriculture is capable of abſorbing a much greater capital than has ever yet been employed in it. Smith's Wealth of Nations, vol. ii. Book ii.

CAPITAL, in *Architecture*. This term is taken immediately from the Italian word *Capitello*, which is derived from the Latin *caput*, head. Thus the etymology of this word deſines its meaning, for the capital is properly the head of a column.

The capitals uſed in the architecture of the Greeks, though with numberleſs minute variations of ornaments and proportions, arrange themſelves into three general claſſes, and offer the moſt obvious diſtinction between the orders. In this ſtyle alſo it is eaſy to diſtinguiſh between thoſe parts which have their uſe and origin in the original type of that wooden conſtruction from which Grecian architecture is derived and thoſe which are merely ornaments and acceſſaries. Conſidering columns in their origin as cylindrical wooden poſts, the abacus which is a ſquare tile or tablet has an evident uſe in ſheltering and protecting the upper part of the column by its projection, and alſo in giving a broader bed and more convenient form for the placing of the architrave. The abacus therefore may be regarded as the original capital which is moſt conſpicuous in that order which bears the marks of the lighteſt antiquity, attenuated and altered in ſucceeding orders and ſucceeding ages, but never omitted either in the purity of Grecian architecture or its deteriorated imitations.

The Doric order, which preſerves more of the primitive type than any other, has a broad and maſſy abacus, which with an ovolo and ſome ſmall fillets, varying in number from three to five, conſtitutes the whole capital. See *Plate* XIII. *Architecture* and *Plate* I. *fig.* 5 and 6.

In the Ionic order we find a very conſiderable variation; here we have a ſmall and moulded abacus, below which depend two ſpiral volutes; there is alſo an echinus and bead, ſee *Plate* XXVIII. *Architecture*. The ſide of the capital is different as the volutes appear only in front, and preſent a pillow or balluſter laterally.

The Corinthian is the moſt richly ornamented of capitals; in this the abacus is hollowed, forming a quadrilateral figure with concave ſides, the angles of which are generally truncated, and in the middle of each ſide there is placed a flower. Below the abacus the capital has the form of a vaſe or bell which is ſurrounded with two tier of leaves. Under each angle of the abacus riſes a volute and caulicoli bend under the flowers which occupy the centres of the ſides. See *Plate* XXIX. *Architecture*.

Such are the general characteriſtics which are common to all theſe capitals, but the variations are numerous. The Doric capital in Grecian examples varies in the more or leſs flattened form of the ovolo, in a greater or leſs number of annulets, in the proportions of the parts to one another, and to the column. In the Doric order, compoſed by modern authors from one or two imperfect Roman authorities, the caſe is very different; here we find a feeble abacus divided with mouldings; an ovolo and annulets, and below this a necking with an aſtragal and fillet. See *Plate* XVI. *Architecture*. The necking is even ſometimes ornamented with huſks and roſes.

The principal variations of the Ionic capital in ancient examples are in the ſize of the volute, the form of its curve, and number of revolutions. In the capital of this order, in the temple of Minerva Polias, at Athens, a beautiful and ſingular inſtance, we obſerve an ornamented necking. See *Plate* I. *Architecture*. The circumſtance of the Ionic capital being diſſimilar in front and ſide, has cauſed conſiderable inconvenience in its uſe. For ſuppoſing a quadrangular portico to be erected of this order, the columns in front would all have the volutes outward, and the capitals at the angles would preſent the balluſter ſide laterally; then either all the columns of the ſide ranges muſt have the balluſter ſide outwards to correſpond with thoſe at the angles, which would be a ſingular abſurdity, or uniformity muſt be violated. To remedy this defect, the ancients made the outer volute of the angular capital project diagonally, ſo as to correſpond equally with a volute in front and one on the ſide. This diſtorted capital, however, was conſidered ſo great a blemiſh, that moſt modern architects, when they had occaſion to uſe Ionic columns on plans fronting two ways, have adopted the invention of Scamozzi, which conſiſts in projecting all the volutes diagonally, thus forming a capital ſimilar every way, while the abacus has the form of the Corinthian abacus, and like that has a flower in the centre of each ſide. It is this which is called the modern Ionic capital; an invention which only obviates the difficulty complained of, by ſpoiling all the capitals, inſtead of merely thoſe at the angles, for in beauty and elegance theſe capitals will not bear the ſmalleſt compariſon with antique examples. This practice was greatly approved at the time, and nearly ſuperſeded the ancient method even in circumſtances where no accommodation was neceſſary.

The Corinthian capital varies in the diviſion and form of the leaves; theſe are directed by Vitruvius to be of the acanthus kind, and thus we find them in the order of the temple of Veſta at Tivoli. The greater number however, both of ancient and modern capitals, are compoſed of olive leaves, which have three, four, or five folds in each diviſion. The general height too varies from 57 to 77 minutes. Perhaps the moſt beautiful example extant of a Corinthian capital, is that of the three columns in the Campo Vaccino at Rome, ſuppoſed to be the remains of a temple of Jupiter Stator. See *Plate* XXIX. *Architecture*.

It remains to ſpeak of the Tuſcan capital. There are no well authenticated remains of this order, and the precepts of Vitruvius on this head are ſo obſcure that the modern compilers of ſyſtems of architecture have of courſe varied exceedingly in their deſigns, and the order that paſſes under this name muſt be regarded rather as a modern than an ancient invention. It has been made to differ from the modern Doric by an air of poverty and rudeneſs, by the ſuppreſſion of parts and mouldings. See *Plate* XIV. *Architecture*.

The Compoſite appears never to have been admitted as a ſeparate order by the ancients (ſee Composite *order*). It will, however, be neceſſary to deſcribe what by modern architects has been denominated the Compoſite capital. This is a combination of Ionic and Corinthian forms; the upper part has the ſhape of a modern Ionic capital, and the lower part is ſurrounded with two tier of acanthus leaves. See *Plate* XXVII. *fig.* 4. *Architecture*. Of this capital there are a few examples at Rome.

From the remains of Egyptian antiquity, it appears, that the architects confined to the ſevereſt ſimplicity in the general forms of their buildings and principles of conſtruction, acknowledged no given rules or orders of architecture for the proportions and ornaments of inferior members. Accordingly we find an infinite variety of capitals, many of them poſſeſſing great richneſs of decoration and elegance of outline. The ornaments are in general accurate imitations of the natural productions of the country, ſuch as the lotus, the reed, or the palm. In *Plate* XXVI. *Architecture*, the reader is preſented with various fragments of Egyptian architecture. Here *fig.* 1, is an elegant capital compoſed of the branches and leaves of the palm and the capſules of its fruit. *Fig.* 2, is a bundle of tufts of palm ſtalks, taken in the ſpring when the branches and leaves are not yet unfolded, and the whole tree reſembles a ſingle flower bud. In *fig.* 6, we may obſerve a conſiderable reſemblance to the volutes of the Ionic capital. *Fig.* 8, is a capital from the temple of Tentyra, compoſed of the head of Iſis and the attributes of this goddeſs.

The temples of the ancient inhabitants of Hindooſtan, works of dateleſs antiquity, preſent many capitals of extraordinary form and compoſition. In ſome of theſe we find repreſented the figures of elephants and horſes, apparently crouching under the weight of the ceiling. Capitals very ſimilar in ideas to theſe are alſo found in the ruins of Perſepolis, compoſed of horſes and camels.

As Roman architecture ſunk into the degraded and barbarous ſtyle, known in this country by the name of Saxon and Norman, which was finally ſuperſeded by the mode commonly called Gothic, ancient rules were forgotten or deſpiſed. Ornaments were abandoned to the caprice of the carver, and an endleſs variety of capitals was produced more or leſs happy according to individual taſte or barbariſm. Variety indeed ſeems to have been the governing principle of decoration, and was purſued to an unmeaning exceſs in contempt of ſymmetry, propriety, and congruity.

Capital, in *Chemiſtry*, ſignifies the head of an alembic.

Capital, in French *capitale*, in *Fortification*, of a work, is an imaginary line dividing that work into two equal and ſimilar parts. Every work in a fortification has its capital. The capital of a baſtion, for inſtance, is the right line drawn from the point or ſaliant angle of it to the middle of the gorge, or from the angle of the interior or inward figure, or polygon, to the ſaliant angle of the baſtion, or flanked angle. A baſtion is ſaid to have a certain number of toiſes or fathoms of capital, when there are juſt ſo many in the diſtance from its ſaliant angle to the point where the two demi-gorges meet each other.

The capital of a ravelin or demi-lune is a right line drawn from the re-entering angle of the counterſcarp to the point or to the flanked or ſaliant angle of the ravelin.

Capital *of a Lantern*, the covering which terminates the lantern of a dome, either in the figure of a bell, as that of the Sorbonne; or of a cupola, or a ſpiral, as that of the church of Sapienza at Rome.

Capital *of a Mill*, the covering thereof in form of a cone, which turns vertically on the round tower, in order to expoſe the ſails to the wind.

Capitals, or *Capital letters*, in *Printing*, denote large or initial letters, which are uſed in the titles of books, and on a variety of other occaſions. It was formerly the cuſtom to begin every noun with a capital; but the practice, being troubleſome, and giving to the writing or printing a confuſed appearance, has been diſcontinued. Capitals, however, may very properly commence the firſt word of every book, chapter, letter, note, or any other piece of writing:—the firſt word after a period, and, if the two ſentences are totally independent, after a note of interrogation or exclamation; but if a number of interrogative or exclamatory ſentences are thrown into one general group, or if the conſtruction of the latter ſentences depends on the former, all of them, except the firſt, may begin with a ſmall letter:—the appellations of the Deity:—proper names of perſons, places, ſtreets, mountains, rivers, ſhips:—adjectives derived from the proper names of places:—the firſt word of a quotation, introduced after a colon, or when it is in a direct form; but when a quotation is introduced obliquely after a comma, a capital is unneceſſary:—the firſt word of an example:—every ſubſtantive and principal word in the titles of books:—and the firſt word of every line in poetry. The pronoun I, and the interjection O, are alſo written in capitals. Other words, beſide the preceding, may likewiſe begin with capitals, when they are remarkably emphatical, or the principal ſubject of the compoſition. Murray's Engliſh Grammar, p. 273, ed. 12.

The ancient MSS. both Greek and Latin, are written wholly in capitals.

In the early days of printing, there were alſo ſeveral editions of books in capitals; as of Homer, the Greek Anthology, Apollonius, &c. Johannes Laſcaris ſeems to have brought the ancient printers to give editions in capitals.

CAPITALIS *reflexa*, in *Surgery*. See Capeline.

CAPITAN, an extravagant *fanfaron*, a forward, vain, impudent braggadocio, who boaſts of great exploits, whilſt he is in reality but ſhy, timid, and daſtardly. It is a term ſometimes made uſe of to denote an abſolute coward or poltroon.

CAPITANA, or Captain *galley*, the chief or principal galley of a ſtate, not dignified with the title of a kingdom. The capitane was anciently the denomination of the chief galley of France, which the commander went on board of. But ſince the ſuppreſſion of the office of captain general of the gallies in 1669 they have no capitana, but the firſt galley is called *reale*, and the ſecond *patrone*.

CAPITANATA, in *Geography*, corrupted from Catapanata, denoting the diſtrict under the *Catapan*, or Greek viceroy, the ancient "Apulia Daunia," but detached from "Apulia" by captain Baſilius Bugiano, or Bagiano, one of its Greek governors, and erected by him into an independent province; one of the 12 provinces of Naples. It is bounded on the north and eaſt by the Adriatic, on the ſouth by the provinces of Bari, Baſilicata, and Principato Ultra, and on the weſt by the Moliſe and Abruzzo Citra. The country is for the moſt part level, has few trees and ſprings; the air is hot, and the ſoil ſandy; nevertheleſs the land, refreſhed by dews, and adjoining the rivers, produces corn, and furniſhes paſture for herds of cattle. The ſprings in the country of Manfredonia, near mount Gargano, the chief mountain of the province, are more plentifully ſupplied with freſh water. The ſides of this mountain afford plantations of oranges; the ſtones dug within it are uſed for building in various parts of the province; and from the top is collected ſnow, which is of great ſervice in this hot country. Along the coaſt, which is defended by a number of towers, there are manufactures of ſalt. Its principal towns are Manfredonia, the capital, Vieſti, Lucera, San Severo, Larino, Troja, Termoli, Bovino, Voltarara, and Aſcoli. The extent of this province comprehends 1,141,622 moggie (5 moggie being equal to 4 Engliſh acres), and the number of inhabitants amounts, according to Swinburne, to 491,255.

CAPITANEATE, in a general ſenſe, the ſame with capitania. Capitaneates, in Pruſſia, are a kind of noble feuds, or eſtates, which, beſides their revenue, raiſe their owners to the rank of nobility. They are otherwiſe called *ſtaroſties*.

CAPITANEI, or Catanei, in Italy, was a denomination given to all dukes, marquiſes, and counts, who were called "capitanei regis." The ſame appellation was alſo given to perſons of inferior rank, who were inveſted with fees, formerly diſtinguiſhed by the appellation of *valvaſores majores*. Du-Cange.

CAPITANEUS, Peter, or Capiteyn, in *Biography*, born of a noble family at Middlebourg in Zealand, in the year 1514, received his education in the univerſities of Louvain and Paris. After taking his degree of doctor, he went to Copenhagen, was made profeſſor in medicine, and firſt phyſician to the king, Chriſtian III.; which offices he appears to have held to the time of his death, which happened in the year 1557, as is ſeen by a chronogram engraved on his tomb:

"Occubuit fatis CapItaneUs aLta MICaret,
JanI ſeXta Ubi LUX horaqUe nona foret."

He was alſo honoured with an epitaph by Ant. Balderſleben.

ben. His works are, "De Potentiis Animæ;" printed in 1550, and "Prophylacticum Conſilium anti-peſtilentiale," publiſhed 1553. It was afterwards given by Thos. Bartholine, in his "Ciſta Medica," printed at Copenhagen in 1662.

Capitaneus, in *Conchology*, a ſpecies of Conus deſcribed by Linnæus: the ſhell is conic, glabrous, with fuſcous baſe; and the ſpire ſomewhat convex.

This is an Aſiatic ſpecies. The colours are various, as olive, yellow, fuſcous, cheſnut, or an intermixture of ſome of them, but is very ſcarce of one colour only. Commonly there are one or two whitiſh bands, with numerous rows of dots, and ſquare or undulated ſpots of a darker colour than the prevailing tint of the ſhell. Many intereſting varieties of this ſpecies are figured by Chemnitz, Favanne, and other writers.

Capitaneus, in *Ancient Law Writers*, denotes a tenant in capite, or chief. See Capite.

Capitaneus *Eccleſiæ*, the ſame with *advocate*, which ſee. Du-Cange, Gloſſ. Lat. tom. i. p. 802.

CAPITANIA, the office or dignity of a captain, and more eſpecially a perpetual feud. See Capitaneate.

Capitania is alſo a denomination given to the twelve governments eſtabliſhed by the Portugueſe in Braſil.

CAPITATÆ, in *Botany*, the ninth claſs in Mr. Ray's ſecond method, containing thoſe compound flowers which are united in a roundiſh form, reſembling a head, as the thiſtle, knapweed, &c. It is alſo the ſecond diviſion of the twenty-firſt order in Linnæus's fragments of a natural method publiſhed in the Philoſophica Botanica; the firſt diviſion of the forty-ninth order at the end of the Genera Plantarum, and in the poſthumous prælections; and the ſecond diviſion of the firſt order of the claſs Syngeneſia in his artificial ſyſtem.

CAPITATE, forming a head; applied particularly to a flower, and to the ſtigma.

CAPITATION, a tax, or impoſition, raiſed on each perſon, in conſideration of his labour, induſtry, office, rank, &c. This kind of tribute is very ancient, and anſwers to what the Greeks called επικεφαλαιον; the Latins, *capita*, *capitatio*, and *tributum*, or *tributum capitis*, or *capitulare*. By this term, taxes on the perſon are diſtinguiſhed from taxes on merchandiſe, which were called *vectigalia, quia vehebantur*.

Capitation obtained among the Jews. Accordingly Moſes ordained (Exod. xxx. 30.), that every Iſraelite ſhould pay half a ſkekel "for his ſoul," or perſon, as a redemption, "that there might be no plague among the people, when they were numbered." Several interpreters have ſuppoſed, that this was intended to take place as often as the people were numbered; and that the evaſion of it, when David numbered his ſubjects, incurred the divine puniſhment of a peſtilence. 2 Sam. xxiv. 1. But it has been more generally maintained, that Moſes laid this tax on all the people, payable yearly, for the maintenance of the tabernacle, for the ſacrifices, wood, oil, wine, flour, habits, and ſubſiſtence of the prieſts and Levites. In the time of our Saviour, this tribute was punctually paid. See Didrachma. The rabbins obſerve that even the prieſts and Jews in general, except women, children under 13 years of age, and ſlaves, were liable to pay the half ſhekel, worth about 1s. 6d. The collectors demanded it in the beginning of Niſan, but had no recourſe to compulſion till the paſſover; when they either conſtrained thoſe to pay who had not paid, or took ſecurity from them.

The Iſraelites, on their return from Babylon, paid one-third part of a ſhekel to the temple; as they were, probably, unable, on account of their poverty, to pay a greater ſum. Nehem. x. 32. After the deſtruction of the temple by the Romans, the Jews were compelled to pay the half ſhekel to the temple of Jupiter Capitolinus, which they had before paid to the temple at Jeruſalem. It was levied through all the provinces where any of them were ſettled, and carried by procurators to Jeruſalem. Cicero obſerves, that Flaccus would not ſuffer that tax, which was collected among the Jews in Italy, to be conveyed thither; and Titus, addreſſing the Jews, reproaches them with ingratitude for employing this tax againſt their benefactors, and in carrying on the war with the Romans, which the emperors of Rome had, by a particular indulgence, permitted them to levy. Calmet.

The mode of aſſeſſment under the Roman emperors ſeemed to unite the ſubſtance of a land-tax with the forms of a capitation. The returns which were ſent of every province or diſtrict, expreſſed the number of tributary ſubjects, and the amount of the public impoſitions. The latter of theſe ſums was divided by the former, and the eſtimate, that ſuch a province contained ſo many "capita," or heads of tribute, and that each head was rated at ſuch a price, was univerſally received, not only in the popular, but even in the legal computation. The value of a tributary head muſt have varied, according to many accidental, or at leaſt fluctuating circumſtances; but it is known, that the rapacious miniſters of Conſtantius had exhauſted the wealth of Gaul, by exacting 25 pieces of gold for the annual tribute of every head; which capitation was reduced by the humane policy of his ſucceſſor to 7 pieces. If we take 16 pieces of gold, or about 9l. ſterling, for a kind of moderate proportion between theſe oppoſite extremes of extraordinary oppreſſion and of tranſient indulgence, we ſhall have probably the common ſtandard of the impoſitions of Gaul. When we reflect on this ſubject, it is obvious, that as long as a very unequal diviſion of property muſt ſubſiſt in ſociety, the moſt numerous part of the community would be deprived of their ſubſiſtence by the *equal* aſſeſſment of a tax, from which the ſovereign would derive a very trifling revenue. But, whatever might be the theory of the Roman capitation, in the practice this unjuſt equality was no longer felt, as the tribute was collected on the principle of a *real*, not of a *perſonal* impoſition. Several indigent citizens contributed to compoſe a ſingle *head*, or ſhare of taxation; while the wealthy provincial, in proportion to his fortune, alone repreſented ſeveral of thoſe imaginary beings. Neverthleſs, the difficulty of allowing an annual ſum of about 9l. ſterling, even for the average of the capitation of Gaul, will be more evident by comparing the ſtate of the ſame country, as it was governed by an abſolute monarch of an induſtrious, wealthy, and affectionate people, before the late revolution. The taxes of France, eſtimated at the annual amount of 18 millions ſterling, may be conſidered as diſtributed among 24 millions of inhabitants. Seven millions of theſe, in the capacity of fathers, brothers, or huſbands, might diſcharge the obligations of the remaining multitude of women and children; and yet the equal proportion of each tributary ſubject would ſcarcely riſe above 50s. of our money, inſtead of a proportion almoſt four times as conſiderable, which was regularly impoſed on their Gallic anceſtors. The reaſon of this difference is to be found, not ſo much in the relative ſcarcity or plenty of gold and ſilver, as in the different ſtate of ſociety in ancient Gaul and modern France. In a country where perſonal freedom is the privilege of every ſubject, the whole maſs of taxes, whether they are levied on property or on conſumption, may be fairly divided among the whole body of the nation. But the far greater part of the lands of ancient Gaul, as well as of the other provinces of the Roman world, were cultivated by ſlaves, or peaſants, whoſe dependent condition was a leſs rigid ſervitude. In ſuch a ſtate the poor were maintained at the expence of their maſters; and as the rolls of tribute were filled only with the names of thoſe citizens who poſſeſſed the means of an honourable, or at leaſt of a decent ſubſiſtence, the comparative ſmallneſs of their number explains and juſtifies the high rate of their capitation. The population of the territory of the Ædui might probably amount to 800,000 perſons; and in the time of Conſtantine, this territory afforded no more than 25,000 *heads* of capitation, of whom 7000 were diſcharged by that prince from the intolerable weight of tribute. By a juſt analogy it may be inferred, that the free and tributary citizens did not ſurpaſs the number of half a million; and if their annual payments may be computed at about 4½ millions of our money, it would appear, that although the ſhare of each individual was four times as conſiderable, a fourth part only of the modern taxes of France was levied on the imperial province of Gaul. The exactions of Conſtantius may be calculated at 7 millions ſterling, which were reduced to 2 millions by the humanity or the wiſdom of Julian. But as this tax, or capitation, on the proprietors of land, would have ſuffered a rich and numerous claſs of free citizens to eſcape, the emperors, with the view of ſharing that ſpecies of wealth which is derived from art or labour, and which exiſts in money or in merchandiſe, impoſed a diſtinct and perſonal tribute on the trading part of their ſubjects. Some exemptions, very ſtrictly confined both in time and place, were allowed to the proprietors who diſpoſed of the produce of their own eſtates. Some indulgence was granted to the profeſſion of the liberal arts; but every other branch of commercial induſtry was affected by the ſeverity of the law; nor did the ſovereign of the Roman empire, who tolerated the profeſſion, diſdain even to ſhare the infamous ſalary, of public proſtitutes. This general tax upon induſtry was collected every fourth year, and hence called the "Luſtral Contribution;" and the fatal period was announced by the tears and terrors of the citizens, who were often compelled by the impending ſcourge to embrace the moſt abhorred and unnatural methods of procuring the ſum at which their property had been aſſeſſed. Gibbon's Hiſt. vol. iii. chap. 17.

Capitation taxes, ſays Dr. Smith, (*ubi infra*,) if an attempt is made to proportion them to the fortune or revenue of each contributor, become altogether arbitrary. The ſtate of a man's fortune varies from day to day, and without an inquiſition more intolerable than any tax, and renewed at leaſt once every year, can only be gueſſed at. His aſſeſſment, therefore, muſt in moſt caſes depend upon the good or bad humour of his aſſeſſors, and muſt, conſequently, be altogether arbitrary and uncertain. Capitation taxes, if they are proportioned not to the ſuppoſed fortune, but to the rank of each contributor, become altogether unequal; as the degrees of fortune are frequently unequal in the ſame degree of rank. Such taxes, therefore, if it is attempted to equalize them, become altogether arbitrary and uncertain; but if it is attempted to render them certain, and not arbitrary, they become altogether unequal. In the different poll-taxes which took place in England, during the reign of William III. the contributors were moſtly aſſeſſed according to their rank, as dukes, marquiſſes, earls, viſcounts, barons, eſquires, gentlemen, the oldeſt and youngeſt ſons of peers, &c. All ſhopkeepers and tradeſmen worth more than 300l. were ſubject to the ſame aſſeſſments, whatever might be the difference in their fortunes. Several of thoſe who in the firſt poll-tax were rated according to their ſuppoſed fortune, were afterwards rated according to their rank. Serjeants, attorneys, and proctors at law, who in the firſt poll-tax were aſſeſſed at three ſhillings in the pound of their ſuppoſed income, were afterwards aſſeſſed as gentlemen. In the capitation tax levied in France, for a long time without interruption, ſince the beginning of the laſt century, the higheſt orders of perſons were rated according to their rank by an invariable tariff; the lower orders of people, according to what was ſuppoſed to be their fortune, by an aſſeſſment that varied from year to year. The officers of the king's court, the judges and other officers in the ſuperior courts of juſtice, the officers of the troops, &c. were aſſeſſed in the firſt manner: the inferior ranks of people in the provinces were aſſeſſed in the ſecond.

In England the different poll-taxes never produced the ſum which had been expected from them. In France the capitation always produced ſuch a ſum. The mild government of England, when it aſſeſſed the different ranks of people to the poll-tax, contented itſelf with what that aſſeſſment happened to produce; and required no compenſation for the loſs which the ſtate might ſuſtain either by thoſe who could not pay, or by thoſe who would not pay, and who, by the indulgent execution of the law, were not forced to pay. The more ſevere government of France aſſeſſed upon each generality a certain ſum, which the intendant muſt find as he could. If any province complained of too high an aſſeſſment, it might, in the aſſeſſment of next year, obtain an abatement correſponding to the overcharge; but it was required to pay in the mean time. Capitation taxes, as far as they are levied upon the lower ranks of the people, are direct taxes upon the wages of labour, and are attended with all the inconveniences of ſuch taxes. They are levied at little expence; and where they are rigorouſly exacted, afford a very ſure revenue of the ſtate. Hence, in countries where the care, comfort, and ſecurity of the inferior ranks of people are not objects of much attention, capitation taxes are very common. It is, however, but a ſmall part of the public revenue, which, in a great empire, has ever been drawn from ſuch taxes: and the greateſt ſum, which they have ever afforded might always have been found, ſays Dr. Smith, in ſome other way much more convenient to the people. Wealth of Nations, vol. iii. b. 5. c. 2.

CAPITATUS, in *Ichthyology*, an obſolete name of that fiſh moſt commonly known in England by the name of Miller's thumb, Cottus Gobio, and river bull-head of approved authors.

CAPITE, in *Law*, an ancient tenure, whereby a perſon held of the king immediately, in right of his crown and dignity, either by knight's ſervice, or ſocage, which ſee. This was the moſt honourable ſpecies of tenure; but at the ſame time it ſubjected the tenants to greater and more burthenſome ſervices than inferior tenures did.

By a ſtatute, 12 Car. II. c. 24. all ſuch tenures by knight's ſervice of the king, or of any other perſon, knights' ſervices *in capite*, with all rights, &c. are annulled: and all ſuch tenures are turned into free and common ſocage; ſo that tenures hereafter to be created by the king are to be in common ſocage only, and not by *capite*, knight's ſervice, &c.

Capite *cenſi*, in *Antiquity*, the loweſt rank of Roman citizens, who in public taxes were rated the leaſt of all, being ſuch as were never worth above 365 aſſes.

They were ſuppoſed to have been thus called, becauſe they were rather counted and marſhalled by their heads than their eſtates. Aul. Gell. lib. vii. cap. 13.

The capite cenſi made part of the ſixth claſs of citizens, being below the *proletarii*, who formed the other moiety of that claſs.

The capite cenſi were not enrolled in the army, as being judged not able to ſupport the expences of war; for in thoſe days the ſoldiers maintained themſelves. It does not appear that before Caius Marius any of the Roman generals liſted the capite cenſi in their armies. Salluſt. Jug. p. 135.

CAPITELLUM, in *Conchology*, a ſpecies of Voluta with an ovate, rugged, knotty ſhell, the pillar of which is triplicated.—Murex capitellum of Linnæus. This is about two inches and three quarters in length; colour white, ſometimes faſciated with fuſcous, and marked with decuſſating ribs. This inhabits the Indian and American ſeas.

CAPITO, Wolfgang-Fabricius, in *Biography*, an eminent Lutheran divine, was born in 1478 at Hagenau in Alſace, and having ſtudied at Baſil, became, in compliance with the deſire of his father, a doctor in medicine. He afterwards graduated both in theology and law; and entering in 1520 into the ſervice of cardinal Albert of Brandenburg, elector of Mentz, received from him letters of nobility. After having embraced the opinions of Luther, he formed an intimacy with Bucer and Oecolampadius, and concurred with them in the eſtabliſhment of proteſtantiſm. He aſſiſted at the council of Marpurg in 1529; and after having been twice married died of the plague in 1542. Among the various works which he wrote we may ſelect the following; viz. "Inſtitutionum Hebraicarum lib. ii;" "Enarrationes in Habacuc et Oſeam;" "Vita Joannis Oecolampadii;" "Reſponſio de Matrimonio, et Jure Magiſtratûs in Religionem." Moreri.

Capito, Titinius, lived under the emperor Trajan, and is mentioned by Pliny (l. viii. ep. 12) as a writer of no mean character. He deſcribed the deaths of illuſtrious men, among whom were ſome of his contemporaries, condemned, without doubt, by Domitian.

Capito, Ateius, a celebrated civilian, who adorned the age of Auguſtus and was diſtinguiſhed by the favour of his ſovereign. He was an opponent of Antiſtius Labeo, who was more illuſtrious by his contempt of that favour, and his ſtern, though harmleſs oppoſition to the tyrant of Rome. Their legal ſtudies were influenced by the various colours of their tempers and principles. Labeo was attached to the form of the old republic; his rival embraced the more profitable ſubſtance of the riſing monarchy. Capito, with the tame and ſubmiſſive diſpoſition of a courtier, ſeldom preſumed to deviate from the ſentiments or at leaſt from the words of his predeceſſors; while the bold republican purſued his independent ideas without fear of paradox or innovation. Labeo decided according to the letter of the law the ſame queſtions which his indulgent competitor reſolved with a latitude of equity more ſuitable to the common ſenſe and feelings of mankind. This oppoſition of ſentiments was propagated in the writings and leſſons of the two founders; and the ſchools of Capito and Labeo maintained their inveterate conflict from the age of Auguſtus to that of Adrian. The two ſects derived their appellations from Sabinus and Proculius, their moſt celebrated teachers. Gibbon's Hiſt. vol. viii. p. 31.

Capito, in *Ichthyology*, an old ſynonym of the Chub, Cyprinus Cephalus, which ſee.

Capito is alſo applied by ſome of the elder writers to the Mullet, Mugil Cephalus, which ſee.

Capito, *anadromus*, one of the ſynonyms of Cyprinus Vimba.

Capito *fluviatilis* (Aldrovandus) Cyprinus Dobula, Mull. and Gmelin.

The true ſpecies to which the names *Capito cæruleus*, and *capito rapax* are applied by obſolete writers do not appear to be very clearly aſcertained.

CAPITOL, Capitolium, in *Antiquity*, a famous fort or caſtle, on the Mons Capitolinus at Rome, wherein was a temple dedicated to Jupiter, thence alſo denominated *Capitolinus*, in which the ſenate anciently aſſembled; and which ſtill ſerves as the city-hall, or town-houſe, for the meeting of the conſervators of the Roman people.

It had its name, *capitol*, from *caput*, a man's head, ſaid to have been found freſh, and yet bleeding, upon digging the foundation of the temple, built in honour of Jupiter. Arnobius adds, that the man's name was Tolus; whence *caput-tolium*. Others ſay, that the hill Tarpeius was called capitol, becauſe it was the capital, or chief fortreſs of Rome.

The firſt foundations of the Capitol were laid by Tarquin the Elder, in the year of Rome 139, B. C. 615. In conſequence of a vow which he had made to Jupiter, Juno, and Minerva, on occaſion of his laſt battle with the Sabines, in which he obtained the victory, he levelled the ſteep top of the Tarpeian hill, marked out the plan of the temple, which he had promiſed to erect, and laid the foundation of that glorious ſtructure, which afterwards became the principal place of the Roman worſhip. Hiſtorians have adorned the foundation of this temple with many prodigies, all portending the future grandeur of the Roman empire. As there were ſeveral gods, who had altars on the ſame hill, and which were to be removed to make room for the new edifice, it was a matter of doubt in what part of the hill the foundations ſhould be dug. The augurs reſolved to conſult each deity one after another, and not to touch their altars before they had given their conſent. All the gods agreed that their altars might be removed, except the god Terminus and the goddeſs Youth, who inſiſted upon not being diſplaced; and this circumſtance gave the augurs occaſion to conjecture, that the bounds of the city and empire ſhould ſtand for ever, and that Rome ſhould always flouriſh with youth and vigour. Accordingly the two deities were encloſed within the walls of the temple. Dionyſius Halicarnaſſenſis places this event under Tarquin the Elder, and Livy under Tarquin the Proud. The ſucceſſor of the former, Servius Tullius, as ſome have ſaid, raiſed the walls; and Tarquin the Proud finiſhed it, A. U. C. 221, B. C. 533, having reſerved for this purpoſe the tenths of the ſpoils of Sueſſa Pomatia, one of the moſt wealthy cities of the Volſci, and having procured a great number of workmen from Etruria, to begin the undertaking, who were aſſiſted in the moſt laborious part, by his own ſubjects. But his expulſion from Rome prevented his accompliſhing all his purpoſes. Thus the edifice was not completed and conſecrated till the third year after the expulſion of the kings, and eſtabliſhment of the conſulate. The ceremony of the dedication of the temple was performed by the conſul Horatius, A. U. C. 246; B. C. 508.

The Capitol occupied eight acres of ground; it was 200 feet broad, and about 215 long. It conſiſted of three parts; a nave, ſacred to Jupiter; and two wings, or ailes, to Juno and Minerva. It was aſcended from the forum by ſtairs; Lipſius reckons one hundred in number, becauſe there were ſo many in the aſcent of the Tarpeian rock. The front which looked to the ſouth, facing the hill Palatinus, and the Forum Romanum, and the ſides were encompaſſed with galleries, wherein thoſe, who had the honour of a triumph, entertained the ſenate at a magnificent banquet, after the performance of ſacrifice to the gods. Both inſide and outſide were enriched with numerous ornaments: the ſtatue of Jupiter, with his golden thunderbolt, his ſceptre, and crown, were the moſt diſtinguiſhed. The gilding of the whole arch of the temple of Jupiter Capitolinus was undertaken by the Romans, according to Pliny (lib. xxxiii.) after the deſtruction of Carthage, and if Plutarch (in Octav.)

tav.) may be credited, it coſt 12000 talents. The gates of the temple were of braſs, covered with large plates of gold. The inſide of the temple and the columns which ſupported it, were all of marble.

In the ſame Capitol there were, likewiſe, a temple to Jupiter the Guardian, and another to Juno; with the mint: and on the deſcent of the hill was the temple of Concord.

The Capitol was burnt in the time of Sylla (A. U. C. 670. B. C. 84), by the negligence of thoſe who kept it. He undertook to rebuild it, but did not live to ſee it finiſhed, which he lamented in his laſt illneſs "as the only thing wanting (ſays Tacitus, Hiſt. iii. 72) to complete his felicity." By his death that charge fell to Q. Lutatius Catulus, as being conſul at the time, B.C. 79, who dedicated it with great pomp and ſolemnity, and had the honour to have his name inſcribed on the front. It was burnt a ſecond time in the reign of Vitellius, the 19th of December, A. D. 69, and rebuilt under Veſpaſian, who completed what Helvidius Priſcus had begun. It was burnt again in the reign of Titus, A. D. 80, and rebuilt by Domitian with a ſumptuous magnificence which had no bounds. But it was always re-erected on the old foundations of Tarquin, and its parts, however highly ornamented, preſerved the ſame proportions.

No remains of the ancient ſtructure are now to be ſeen; but the preſent edifice was built on the ſame ſpot by pope Boniface IX. Gregory XIII. and Clement VIII. and at firſt conſiſted of two wings. It was completed by the ſame Clement, Innocent X., and Alexander VII. and is now a very magnificent palace. The roof of it is flat, and adorned with many ſtatues of illuſtrious perſons among the Romans. In the new building reſides the ſenate of Rome, who daily adminiſter juſtice there; and in the wings are the apartments of the conſervators of the city. There is alſo room enough for keeping antiquities and other curioſities which the traveller of taſte has always admired. The "Camera apoſtolica," or apoſtolic chamber, has now uſurped the rights of the famous "Senatus Populuſque Romanus." In the front of this building is a high tower, with the ſtatue of religion erected on the top of it. The double flight of ſteps at the entrance of this palace is the work of Michael Angelo, who likewiſe adorned the front with a ſuperb fountain, and two ſtatues repreſenting the Nile and the Danube in a reclining poſture. In the centre is a porphyry ſtatue of Rome, in the habit of Minerva, and the uſual ſymbols of the helmet and ſpear, but ſitting. This is a piece of great antiquity, and much admired by connoiſſeurs. The large hall, where the court of juſtice is held by the ſenators, was formerly adorned with ſeveral pictures, repreſenting the achievements of the kings of the Romans; but none of them now remain; Clement XI. having, in 1712, ſupplied their places with a great number of deſigns, exhibiting the life of pope Pius V. and his canonization. Under the "Corps de Logis" is the capital priſon. In the apartments of the conſervators, in the left wing, are two celebrated ſtatues of Julius Cæſar and Auguſtus, both antiques and of white marble. The former, as ſovereign of the world, holds a globe in his hand; the latter, a roſtrum or beak of a ſhip, alluding to his victory over Mark Antony and Cleopatra. Near theſe ſtatues are to be ſeen two feet and a hand of oriental marble, being part of a coloſſus or ſtatue of Apollo, which was 30 ells in height, and ſent by Marcus Lucullus from Apollonia to Rome, where it was placed on the Capitoline mount. Oppoſite to this is the head of the Coloſſus. Here are alſo another large head and hand of braſs, ſuppoſed to have belonged to a coloſſus of Commodus or Domitian. Near the inſcription on Agrippina's monument is an admirable ancient groupe, repreſenting a lion tearing to pieces a horſe; but the horſe is much damaged by time. This admired piece was found on the banks of the Tiber, near the Oſtia gate, in the time of Paul III. Here is alſo a very remarkable piece of architecture, in which five pieces of ſculpture are conjoined, which had originally no connection, and were dug up in different places. In the centre, and elevated above the reſt, ſits Rome triumphant, in white marble, with a poniard in her left, and a branch of palm in her right hand; and on the front of the baſe, on which ſhe ſits, is a woman in tears, repreſenting Dacia, or ſome other conquered province. On each ſide of this ſtatue is the coloſſus of a barbarian prince in a kind of black marble, called "baſaltes." Their rank may be known by their diadems. The workmanſhip is exquiſite; but it is not known who they are. Here is alſo the marble ſarcophagus of the emperor Alexander Severus and his mother Julia Mammæa, found on Monte del Grano, near Freſcati, and brought hither. It is ſix feet long, and ſix broad. Not far from this is a marble coloſſal ſtatue of Conſtantine the great, which ſhews that the art of ſculpture was upon the decline, though the two muſes are good pieces, as is alſo a prieſteſs of Bacchus. Near the ſtairs is a very remarkable antique, viz. the "columna roſtrata," which is of Parian marble; erected in the year of Rome 494, in honour of the conſul Caius Duilius, on account of a naval victory, which he obtained over the Carthaginians. Near it is a baſſo-relievo, repreſenting Curtius leaping into the abyſs. At the firſt landing place are ſeen two antique muſes; and a little farther, four admirable baſſo-relievos, repreſenting the triumph of Marcus Aurelius and Lucius Verus, which belonged to their triumphal arch in the Corſo. Before the entrance of the great hall is a large ſturgeon, 6½ ſpans long, cut in white marble; the head of every fiſh of this ſpecies, exceeding that meaſure, being due to the conſervators of the city. On the left hand are the Faſti conſulares, down to the time of the emperor Pertinax, engraved on marble; and above theſe is a baſſo-relievo of the wolf ſuckling Romulus and Remus. Farther in are the names of the modern conſervators. In the firſt hall are ſome paſſages of the Roman hiſtory, painted by Gioſeppi d'Arpino; as, the rape of the Sabines, the combat betwixt the Horatii and Curatii, Romulus and Remus ſucking the ſhe-wolf, and the building of the city of Rome, &c. &c. But the moſt admired of all is the victory of Tullius Hoſtilius over the Veji and the Fidenates. There are various other marble ſtatues and paintings in the different apartments, which it would exceed our limits to mention, but which muſt be highly gratifying to the curious.

From ſeveral remains of ancient walls, it is conjectured by ſome, that the temple of Jupiter Capitolinus ſtood on the ground which is at preſent incloſed in the court of the Caffarelli palace. The famous Tarpeian rock is now almoſt covered with buildings; but it is evident that anciently the rock muſt have been much ſteeper, or a wall muſt have been erected upon it, from which malefactors were thrown down headlong. That the height or depth of it has not undergone any conſiderable alteration may be concluded from Severus's triumphal arch at the foot of the Capitoline-hill, which, with the amphitheatre in its neighbourhood, is not above two or three feet below the preſent ſurface of the ground. See Keyſler's Travels, vol. ii.

Anciently, the name capitol was likewiſe applied to all the principal temples, in moſt of the colonies throughout the Roman empire: as, at Conſtantinople, Jeruſalem, Carthage, Ravenna, Capua, &c.

CAPITOLIA, or ÆLIA CAPITOLIA, in *Ancient Geography*, a name given to Jeruſalem in the time of Ptolemy.

CAPITOLIAS, a town of Aſia in Cœloſyria, N. of Adraa, according to Ptolemy; between Adraa and Gadara, according to the table of Peutinger; and in Antonine's route from Seriana to Scythopolis, between Neva and Gadara.

CAPITOLINE *Games*, *Ludi* Capitolini, were annual games, or combats, inſtituted by Camillus, in honour of Jupiter Capitolinus; and in commemoration of the Capitol's not being ſurpriſed by the Gauls.

Plutarch tells us, that a part of the ceremony conſiſted in the public cryer's putting up the Hetrurians to ſale by auction: they alſo took an old man, tying a golden bulla to his neck, ſuch as were worn by their children, and expoſed him to the public deriſion. Feſtus ſays, they dreſſed him in a prætexta, and hung a bulla at his neck: not as accounting him a child, but becauſe this was an ornament of the kings of Hetruria.

There was alſo another kind of capitoline games, called *agones capitolini*, inſtituted by Domitian, A.U.C. 839, A.D. 86, and celebrated each fifth year; wherein there were rewards and crowns, or garlands of oak-leaves, beſtowed on the victorious poets, and put on their heads by the emperor himſelf. As the manner and plan of the capitoline games were taken more from the Greeks than from the Romans, Domitian preſided in them, dreſſed after the Greek faſhion, and wearing a crown of gold, in which were ſet the images of Jupiter, Juno, and Minerva. He was attended by the prieſt of Juno, and the college of prieſts, which he himſelf had inſtituted in honour of the Flavian family; all dreſſed like himſelf, except that they wore an image of the emperor in their crowns. If the crowns were given to ſuperior merit, the excluſion of Statius, (Capitolia noſtræ inficiata lyræ, Silv. l. iii. v. 31.) may do honour to the games of the Capitol; however, though he could not obtain the prize at theſe games, he was crowned three times at thoſe of Minerva, in honour of whom Domitian celebrated a feaſt every year, in his houſe at Alba, with great pomp and magnificence. Theſe games, which were not aboliſhed in the 4th century, became ſo celebrated, that the manner of accounting time by luſtres, which had obtained till then, was changed; and they began to count by capitoline games, as the Greeks did by olympiads. The feaſt was not for poets alone, but alſo for athletæ, orators, hiſtorians, comedians, muſicians, &c.

Capitoline *Marbles*. See Fasti.

CAPITOLINI, in *Roman Antiquity*, a college of men reſiding in the capital and arx, to whom was committed the care of celebrating the capitoline games.

CAPITOLINUS, Julius, in *Biography*, a Latin hiſtorian, flouriſhed at the cloſe of the third, and beginning of the fourth century, and wrote the lives of the emperors Antoninus Pius, Verus, Albinus, Macrinus, the two Maximins, and the three Gordians. Theſe are extant, but ſome other of his compoſitions are loſt. His matter is chiefly copied from Herodian, and he is deemed neither a pure nor an exact writer. Voſſ. Hiſt. Latin.

CAPITOUL, or Capitol, an appellation given to the chief magiſtrates of Toulouſe, who have the adminiſtration of juſtice and policy both civil and mercantile in the city.

The capitouls at Toulouſe are much the ſame with the echevins at Paris, and the conſuls, bailiffs, burgher-maſters, mayors, and aldermen, &c. in other cities. In ancient acts they are called *conſules capitularii*, or *capitolini*, and their body *capitulum*. From this laſt come the words *capitularii* and *capitouls*. The appellative *capitolini* aroſe hence, that they have the charge and cuſtody of the town-houſe, which was anciently called capitol. The office only laſted one year, and ennobled the bearers. In ſome ancient acts they are called *capitulum nobilium Toloſæ*. Thoſe who have borne it, ſtyled themſelves afterwards burgeſſes. They were called to all general councils, and had the *jus imaginum*; that is, when the year of their adminiſtration expired, their pictures were drawn in the town-houſe; a cuſtom which they retained from the ancient Romans, as may be ſeen in Sigonius.

CAPITOULATE, an appellation given to the ſeveral quarters or diſtricts of the city of Toulouſe, each under the direction of a capitoul; much like the wards of London under their aldermen.

Toulouſe is now divided into eight capitoulates, or quarters, which is ſubdivided into *moulans*, each of which has its tithing-man, whoſe buſineſs is to inform the capitoul of what paſſes in his tithing, and to inform the inhabitants of the tithing, of the orders of the capitoul. See Toulouse.

CAPITULA Ruralia, denote chapters held by the rural dean and clergy within the precincts of each deanery, anciently held every three weeks, then once a month, and more ſolemnly once a quarter.

CAPITULAR, or Capitulary, denotes an act paſſed in a chapter, either of knights, canons, or religious.

The capitularia, or capitulars of Charlemagne, Charles the Bald, &c. are the laws, both eccleſiaſtical and civil, made by thoſe emperors in the general councils, or aſſemblies of the people: which was the way in which the conſtitutions of moſt of the ancient princes were made; each perſon preſent, though a plebeian, ſetting his hand to them.

Under the French monarchs of the firſt race, the general aſſemblies of the nation met annually at ſtated ſeaſons, and extended their authority to every department of government. The power of electing kings, of making laws, of redreſſing grievances, of paſſing judgment in the laſt reſort, with reſpect to every perſon and to every cauſe, and of conferring donations on the prince, reſided in this great council of the nation. Under the ſecond race of kings, notwithſtanding the power and ſplendour which the conqueſts of Charlemagne added to the crown, the general aſſemblies of the nation continued to poſſeſs extenſive authority. The right of determining which of the royal family ſhould be placed on the throne, was veſted in them. The princes elevated to that dignity were accuſtomed regularly to call and conſult them with reſpect to every affair of importance to the ſtate, and without their conſent no law was paſſed, and no new tax was levied. Theſe aſſemblies of the nation, diſtinguiſhed by the name of Conventus, Malli, Placita, were regularly convened once a year at leaſt, and frequently twice in the year. The nobles, the dignified eccleſiaſtics, and the great officers of the crown, were not the only members of the national council; the people, or the whole body of freemen, either in perſon, or by their repreſentatives, had a right to be preſent in it. Monteſquieu indeed, in his "Spirit of Laws," (vol. ii. p. 248), ſays, that under the firſt and ſecond race, the nation was often aſſembled; that is, the lords and biſhops; and that the commons were not yet thought on. But it appears from Hincmarus, archbiſhop of Rheims, and Agobardus, archbiſhop of Lyons, cited by Dr. Robertſon, in his "Hiſtory of Charles V." (vol. i. p. 438), that the people, as well as the members of higher dignity, formed a part of theſe aſſemblies, and participated in the legiſlative power. Thus, by a law, A.D. 803, it is ordained, "that the queſtion ſhall be put to the people with reſpect to every new law, and if they ſhall agree to it, they ſhall confirm it by their ſignature." Capit. vol. i. 394. There are two capitularia, which convey to us a full idea of the part which the people had in the adminiſtration of government. When they felt the weight of any grievance, they had a right to petition the ſovereign for redreſs. One of theſe petitions is ſtill extant: it is addreſſed to Charlemagne, A. D. 803, and expreſſed in ſuch terms as could have been uſed only by men conſcious of liberty, and of the extenſive privileges which they poſſeſſed. They concluded with requiring him to grant their demand, if he wiſhed that they ſhould any longer continue faithful ſubjects to him. This great monarch made no remonſtrance, but ſignified his willingneſs to comply; and ſenſible that he himſelf did not poſſeſs legiſlative authority, he promiſes to lay the matter before the next general aſſembly, that ſuch things as were of common concern to all might be then conſidered and eſtabliſhed by common conſent. Capitul. tom. i. p. 405—409. As the people by their petitions brought matters to be propoſed in the general aſſembly, we learn from another capitular, the form in which they were approved there, and enacted as laws. The propoſitions were read aloud, and then the people were required to declare whether they aſſented to them or not. They ſignified their aſſent by exclaiming three times, "we are ſatisfied;" and then the capitulare was confirmed by the ſubſcription of the monarch, the clergy, and the chief men of the laity. Capitul. tom. i. p. 627. A. D. 822. From a capitulare of Carolus Calvus, A. D. 851, it ſeems probable, that the ſovereign could not refuſe his aſſent to what was propoſed and eſtabliſhed by his ſubjects in the general aſſembly. Tit. ix. §. 6. Capitul. vol. ii. p. 47.

Some diſtinguiſh the capitulars from laws; and ſay, they were only ſupplements to laws.—They had their name, *capitulars*, from their being divided into *capitula*, chapters or ſections. In theſe capitulars did the whole French juriſprudence anciently conſiſt. In proceſs of time, the name was changed for that of ordonnances.

The weakneſs of the greater part of the monarchs of the ſecond race, and the diſorder into which the nation was thrown by the depredations of the Normans, encouraged the barons to uſurp an independent power formerly unknown in France. The political union of the kingdom was at an end, its ancient conſtitution was diſſolved, and only a feudal relation ſubſiſted between the king and his vaſſals. The regal juriſdiction extended no farther than the domains of the crown. Under the laſt kings of the ſecond race, they were reduced almoſt to nothing. Under the firſt kings of the third race, they comprehended little more than the patrimonial eſtate of Hugh Capet, which he annexed to the crown. All theſe circumſtances rendered it eaſy for the barons to uſurp the rights of royalty within their own territories. Hence, the capitularia became no leſs obſolete than the ancient laws: local cuſtoms were every where introduced, and became the ſole rule by which all civil tranſactions were conducted, and all cauſes were tried. The wonderful ignorance which became general in France, during the 9th and 10th centuries, contributed to the introduction of cuſtomary law. Few perſons, except eccleſiaſtics, could read; and as it was not poſſible for them to have recourſe to written laws, either as their guide in buſineſs, or their rule in adminiſtering juſtice; the cuſtomary law univerſally prevailed. Another circumſtance that greatly contributed to the diſuſe of the capitularies, as well as of the Salic and Roman laws, was the great extent given at this time to judiciary combats. During this period, the general aſſembly of the nation ſeems not to have been called, nor to have once exerted its legiſlative authority. Local cuſtoms regulated and decided every thing. The laſt of the capitularia collected by M. Baluze, was iſſued in the year 921, by Charles the Simple. One hundred and thirty years elapſed from that period to the publication of the firſt ordonnance of the kings of the third race, contained in the great collection of M. Lauriere; and the firſt ordonnance, which appears to be an act of legiſlation, extending to the whole kingdom, is that of Philip Auguſtus, A. D. 1190; and the ordonnances previous to this reign, contain regulations, the authority of which did not extend beyond the king's domains. See ORDONNANCE. Baron Monteſquieu obſerves, (Sp. of Laws, vol. ii. p. 250.) that there were ſeveral ſorts of capitularies. Some had relation to political government, others to economical, moſt of them to eccleſiaſtical polity, and ſome few to civil government. Thoſe of the laſt ſpecies were added to the civil law, that is, to the perſonal laws of each nation; for which reaſon, it is ſaid in the capitularies, that there is nothing ſtipulated therein contrary to the Roman law. In reality, thoſe capitularies that regarded economical, eccleſiaſtical, or political government, had no relation to that law; and thoſe concerning civil government had reference only to the laws of the barbarous people, which were explained, amended, enlarged, and retrenched. But the addition of theſe capitularies to the perſonal law, occaſioned, as Monteſquieu conceives, the neglect of the very body of the capitularies themſelves: as in times of ignorance, the abridgment of a work often cauſes the loſs of the work itſelf. Anſegiſe is ſaid to have made the firſt collection of regulations contained in the capitulars of Charlemagne and Louis le Debonnaire; which collection is divided into four books, and has been approved by Louis le Debonnaire, and Charles the Bald. After him, Benoit collected, about the year 845, the capitulars of theſe two emperors, omitted by Anſegiſe, and annexed to them the capitulars of Carloman and Pepin. This collection is divided into three books, which comprehend, with the four preceding, the ſeven books of the capitulars of the French kings: the ſix firſt of theſe were publiſhed by du Tillet in 1548, and the whole collection of ſeven books by M. M. Pithou. Father Sirmond has publiſhed ſome capitulars of Charles the Bald; and at length, M. Baluze printed a complete edition of the capitulars in 2 vols. fol. at Paris in 1677. This contains the capitulars of the French kings, and the collections of Anſegiſe and Benoit, together with ſome other pieces.

The biſhops alſo in the 8th and following centuries gave the name of capitula and capitulars to the regulations which they enacted in their ſynodal aſſemblies, with regard to eccleſiaſtical diſcipline, deducing them from the canons of councils, and the works of the fathers. Theſe regulations had the force of laws only in the dioceſe of the prelate who publiſhed them, unleſs they were approved by a council, or the metropolitan; in which caſe, they were obſerved through the whole province. Of this kind are the collections of Martin, archbiſhop of Braga, in the year 525; thoſe of pope Adrian I., given to Angilram, or Enguerran, biſhop of Metz, in 785; thoſe of Theodulphus, biſhop of Orleans, in 767; thoſe of Hincmar, archbiſhop of Rheims, in 852; thoſe of Herard, archbiſhop of Tours, in 858; and thoſe of Iſaac, biſhop of Langres. Doujat, Hiſt. du Droit canon. Baluze, Præf ad Capit. M. du Pin. Eccl. Ant. of the 8th century.

CAPITULATION, in *Military Language*, a particular convention, agreement, compact, or treaty between two powers. Thus, one power makes a capitulation with another to furniſh him with troops on condition of ſubſiſtence, pay, and certain privileges, or for other military ſuccours or aſſiſtance. A corps or body of troops conſtrained to ſurrender themſelves makes a capitulation with that, which forces it to do ſo. A governor or commandant of a place beſieged enters into a capitulation with the general of the beſieging army when he is under the neceſſity of delivering it up.

The ſurrender of a place by capitulation is juſtifiable and honourable, or otherwiſe, in proportion to the ability, ſkill, perſeverance, and valour, with which it has been defended.

Many governors truſting too much to their courage and the vigour of their arms are negligent in making themſelves acquainted with, and practiſing the means of enabling them to defend the places entruſted to their care as long and obſtinately as poſſible, and to the beſt advantage. This knowledge, however, is of the firſt importance, and highly eſtimable. They think they fulfil and diſcharge their duty ſufficiently if they expoſe their own lives on all occaſions, either offering themſelves or ſought for. The examples of ſeveral places, which, though taken through want of good conduct, have nevertheleſs been defended with a conſiderable degree of valour and eclat, are apt to lead them into this error. But they would have no reaſon to dread the blame that might attach to their ſurrendering ſooner than they ought, were they to add to their valour that knowledge of defence, which they but too often neglect to acquire.

They believe, that when their outworks are taken, and the miner is attached to the body of the place, or at the moſt, if the baſtion be at all opened, or a breach made in it, they may ſurrender and capitulate with honour after appearing ſword in hand on the top of the breach at the head of a battalion, that does not fight but only faces the fire of the cannon and muſquetry of the attack, and then retires from the breach behind ſome trifling and weak retrenchment, that appears to have been made more for the capitulation of the troops than for the defence of the place. Such prompt capitulations are ſometimes occaſioned and brought about by the reaſonings and importunity of the other officers, who urged by ſelf-intereſt wiſh to preſerve the little baggage and effects that belong to them, and preferring the preſervation of them to their real glory, perſuade the governor, who for particular reaſons of his own wiſhes alſo perhaps to be perſuaded, that he may capitulate with honour; that it is much better to ſecure by a voluntary treaty the liberty of the inhabitants and to march out drums beating, colours flying, arms loaded, *balle en bouche* to reload them with, matches lighted, and with ſome pieces of cannon, their baggage and effects, than to await an approaching extremity and to run the riſk of being ſtormed or having the place carried by force. They repreſent to him, that one part of the ſoldiers are wounded, that others are ſick, and that thoſe, who are ſtill in a condition for ſervice, are diſcouraged and diſheartened; that their long watchings, their ſevere fatigues and ſufferings, well entitle them to his moſt ſerious attention to their ſafety and preſervation. By urging theſe and many ſuch other bad reaſons, they endeavour to make him form the reſolution, which he has himſelf perhaps already taken, of capitulating, and of which he is probably well pleaſed in his own mind, that they have made him the overture or propoſal, ſince, after ſome formalities, he concludes with them on ſurrendering up the place; as if a baſtion, that is not perhaps bared or ſtripped of its revetement in more than one ſpot, furniſhed a free and eaſy entrance to the enemy, or as if the ſtate to which the place belongs had gone to the expence of erecting the works and reveting the ramparts for no other purpoſe than that of procuring ſuch a capitulation, as troops often make in ſmall and bad redoubts, and ſometimes in the open field. Such conduct is baſe and diſhonourable, and ſuch ideas are grafted on ignorance of the proper method of defending works by means of retrenchments one after another, which is not only poſſible but practicable; and every governor or commandant, that underſtands and does his duty, will put in practice.

Many and numerous, indeed, are the contrivances for rendering the defence of a fortified place long and ruinous to the beſieger, if the governor and other officers of it were better inſtructed in their duty than they commonly are, and would ſacrifice their intereſt to their glory and the good of their country. The governor or commandant of ſuch a place, beſides doing the utmoſt in his power to have it at all times ſupplied with a ſufficiency of troops, proviſions, artillery, ammunition, medicines, and every thing elſe, that is neceſſary for the ſupport and comfort of the garriſon in order to enable him to defend it properly and ſtand a ſiege, he ſhould before it is inveſted or even expected to be beſieged, take care that there are no ditches, fences, buildings, or any thing elſe within cannon-ſhot of the glacis or covert way, that can ſerve to cover the enemy from his view, or ſhelter them in opening their trenches. He ſhould have every ditch filled up, every fence and tree cut down, and even every little eminence or riſing ground within that diſtance levelled if poſſible. Many of the governors, however, and principal officers of ſuch places act in time of peace as if they ſuppoſed they were never to be inveſted, and totally neglect their environs. They permit the inhabitants to make gardens, to ſurround theſe with ditches and fences, to plant trees, and even to erect buildings within cannon-ſhot of their works; and the moment an enemy appears before the ſame they are often ſo ignorant of their duty as to attempt to cannonade him and to throw their ſhot at him to as great a diſtance as they are able, as if they wiſhed to facilitate his enterpriſe or to aid and aſſiſt him in the execution of his deſign by pointing out to him the very ground where he ought to form his encampment, and the diſtance at which he ſhould open his trenches and commence the attack. The beſieged, however, remaining quiet inſtead of purſuing ſuch injudicious conduct, is uſually attended with one or other of the two following advantageous circumſtances; namely, that the beſiegers fix their camp either too near to the place, or farther from it than is neceſſary. If it be too far off, the line of circumvallation becomes too extenſive, and is of courſe leſs calculated than it otherwiſe might be for preventing ſuccours from getting into the place. And if, on the other hand, it be too near, the beſiegers after ſome days when the cannon of the place begin to fire on them will be obliged to move it farther off; by which means the line of circumvallation muſt be commenced anew, and their time and labour will be loſt, which, at the beginning of a ſiege, is all that the beſieged can expect or deſire.

As it is cuſtomary for the enemy a day or two after the opening of the trenches and ſometimes on the very ſame day to advance in order to reconnoitre the places moſt convenient or commodious for the attack, and as this reconnoitring is often performed by the general of the beſieging army himſelf, that he may know what reſolution to take reſpecting it; the governor or commandant of the place ſhould take particular care that none of his people are made priſoners. For even the moſt ignorant of them might furniſh uſeful intelligence to the enemy.

When the beſieging army is weak he may ſend out a large body of troops to keep them at a diſtance by means of muſquetry. But when it is ſtrong, he ſhould not leave without the place, but a ſmall number of cavalry or infantry, with directions by a feigned retreat to draw the enemy into a ſituation that will expoſe them to the fire of the works if they attempt to approach and charge them.

The governor or commandant of a fortified place ſhould know how to counteract and protract the operations of the beſiegers by means of counter-approaches, by ſorties or ſallies, by mines, &c.; all which he ought to make uſe of and put in practice, diſputing every inch of ground, as well as various contrivances for rendering breaches impracticable after they appear to be practicable to the enemy, before he ſeriouſly thinks of capitulating. Before the place, intruſted to his care, is actually attacked, he ſhould frequently weigh and ponder in his own mind every poſſible or practicable method of attacking it, that he can imagine or conceive, and then endeavour to find out as many different ſorts of defence for counteracting and prolonging them. Such mental reflection and examination would render it almoſt impoſſible for any occurrence to take place during a ſiege, that he had not already thought of, or that did not at leaſt bear ſome reſemblance to what he had thought of, and would enable him to draw from this likeneſs or ſimilitude prompt reſources and expedients.

The articles of capitulation are propoſed by the governor or commandant of the place beſieged, who receives hoſtages for the ſafety and ſecurity of thoſe, whom he ſends to the general of the enemy. It is cuſtomary to give hoſtages of equal rank reciprocally.

The ſtipulation of the articles propoſed, the alteration, modification, or refuſal of ſome of them, is governed by a variety of conſiderations depending on the views and knowledge or information of the general, who conducts the ſiege.

When the articles are ſigned, the beſiegers take poſſeſſion of ſome poſt, or of a front attacked, according as it is agreed on.

When the time arrives, at which the garriſon is to march out, it is uſual to introduce into the place by way of honour and diſtinction the oldeſt corps of the army of the beſiegers, which occupies poſts for guarding it; and after the beſieged have left it, thoſe corps are marched into it, that are intended to garriſon it.

The examination of the artillery, ammunition, ſtores, and proviſions, that ought to remain in the place agreeably to the capitulation, precedes the going out of the garriſon which is always done in concert by the officers of artillery, ſtore-keepers, and commiſſaries, who exchange ſigned accounts, or ſtatements and diſcharges, from which the general gives orders for providing the place with what is wanted.

The troops, that march out, receive an eſcort ſufficient for conducting them ſafe to the place appointed by the capitulation; an article, which of all others is in general moſt religiouſly obſerved.

After the marching out of the garriſon, the firſt object of attention is the levelling and deſtruction of the works that were erected or thrown up for the attack of the place, and the repairing of all thoſe, that were injured or damaged by the ſame. The beſieging army, indeed, ought not to quit their lines after the place capitulates till they have filled them up, and either removed their heavy artillery into the place, or ſent it elſewhere with whatever is not neceſſary for its defence. Then they may leave them either for the repoſe and refreſhment of the troops fatigued with the ſiege, or for the convenience of ſubſiſtence, or to execute the remaining part of the plan of the campaign.

When the governor or commandant of a fortified place, after having made every practicable preparation for, and exhauſting all his means of defence, is reduced to the neceſſity of capitulating, in order to obtain as favourable conditions as he poſſibly can both for his garriſon and for the inhabitants, he orders one or more drummers to repair to that part of the rampart, which is next to the attack, and to give notice to the beſiegers, by beating the *chamade*, that he has ſome propoſals to make. For the ſame purpoſe one or more white colours are ſet up on the rampart, and one of them remains either on it or on the breach during the negociation. The ſame formality is obſerved, when after a violent attack a ſuſpenſion of arms is demanded, either for the purpoſe of burying the dead or for carrying off the wounded.

After the beating of the *chamade*, the governor or commandant ſends ſome officers of diſtinction to the commander in chief of the beſiegers to deliver to him the conditions, on which he propoſes to ſurrender up the town, place, or city. As a ſecurity, however, for the officers ſent from the garriſon, the beſiegers ſend an equal number generally of the ſame rank into the place. When the governor's propoſals are not ſatisfactory to the general of the beſieging army, he on his part preſcribes the conditions, on which he expects it to ſurrender, commonly threatening to allow the governor no terms whatſoever in caſe he do not accede to thoſe preſcribed within a certain time, or before ſuch or ſuch a work ſhall be finiſhed. If the beſieged find the terms or conditions inſiſted on by the beſiegers to be too hard or rigorous, the officers ſent to them return to the beſieging army, and thoſe ſent by them return into the garriſon. The drummers are directed to beat their drums upon the rampart, that every one may have timely notice to retire before hoſtilities recommence, which they do very ſoon afterwards. During the negociation or ſuſpenſion of arms no work ought to be erected or even repaired, either by the beſieged or by the beſiegers. It is neceſſary, however, to be on the watch at that time as much as at any other, and ſtrictly to guard every point liable to be attacked, to prevent any ſurpriſes by ſtratagem, which are regarded as warrantable and lawful.

But if the terms or condicions of the capitulation be agreed on, the governor or commandant ſends two or three of his principal officers into the camp, and the beſieging general ſends the ſame number of officers of equal rank into the place, as a ſecurity for its accompliſhment. When the beſieged have performed every thing agreeably to the compact or treaty, their hoſtages are ſent back to them, as are thoſe of the beſiegers as ſoon as the terms, they agreed to, are complied with.

The terms or conditions of a capitulation vary with circumſtances and ſituations; but they are generally to the following purport.

1. The garriſon ſhall march out through the breach with their arms, baggage, horſes, drums beating, matches lighted at both ends, *balle en bouche*, colours flying, a certain number of pieces of cannon and mortars, with their appurtenances, ſpare carriages, ammunition for a certain number of charges; to be conducted in ſafety *by the ſhorteſt road*, or by a ſpecific route, to the neareſt town or place belonging to the beſieged, and if the diſtance be ſo great as to require a march of ſeveral days, to be provided with proviſions and lodgings during that time.

2. That one of the gates ſhall be delivered up to the beſiegers the evening of the day on which the capitulation or convention is ſigned, or at a certain hour next day, and that the garriſon ſhall march out a day or two after, according to agreement.

3. The beſiegers ſhall furniſh a certain number of covered waggons, which are not to be ſearched, beſides others for carrying the wounded and ſick that are in a condition to be tranſported, and in general all the carriages and horſes neceſſary for removing the garriſon's baggage, and the artillery allowed by the capitulation.

4. That the ſick and wounded who cannot be removed or carried off, and are obliged to be left behind in the place,

ſhall have free liberty to go away, with every thing that belongs to them, when they are in a condition to do ſo; and they ſhall in the mean time be furniſhed with lodgings, and with proviſions, *gratis*, or *otherwiſe*, and have every ſort of medical aid or aſſiſtance that can well be afforded to them.

5. There ſhall be no indemnification required from the beſieged for any horſes taken from the inhabitants, or for any houſes burnt or deſtroyed during the ſiege.

6. The governor or commandant, the officers under him, and thoſe belonging to the garriſon, the garriſon itſelf, and in general every one in the king's, prince's, or ſtate's ſervice, ſhall freely quit the place without repriſals of any kind.

7. That the inhabitants ſhall exerciſe their religion according to their accuſtomed forms of worſhip, without hindrance or moleſtation.

8. The inhabitants, both of the place and its dependencies, ſhall be maintained in all their rights, privileges, and prerogatives.

9. Thoſe that chooſe to leave the place ſhall have free liberty to go whither they pleaſe with their effects; and ſuch of the inhabitants as have ſhewn a partiality to the garriſon, or aſſiſted them during the ſiege, ſhall not be moleſted on that account.

10. All the remaining powder and ammunition ſhall be delivered up to the beſiegers, and the loaded mines ſhall be ſhewn and pointed out to them.

11. All the priſoners made on both ſides during the ſiege ſhall be releaſed.

A garriſon ſhould have a ſufficiency of proviſions and ammunition to laſt for three days to entitle them to a convention or capitulation. But if they have not near ſo much of either, at the ſigning of the capitulation, they cannot in juſtice be afterwards regarded as priſoners of war, becauſe the beſiegers were not at the time acquainted with the circumſtance.

If the beſiegers will not agree to any other ſtipulation than the beſieged's being made priſoners of war, and the garriſon is not in a condition to hold out any longer, it is generally endeavoured to render the conditions as little burthenſome and rigorous as poſſible; ſuch, for inſtance, as the following:

1. That the governor or commandant, and the principal officers, ſhall keep their ſwords, piſtols, baggage, &c.

2. That the ſubalterns ſhall keep their ſwords and baggage.

3. That the common men ſhall not be rifled or diſperſed about from their regiments.

4. That the garriſon ſhall be conducted by the ſhorteſt road to a certain place, and there remain priſoners of war.

5. That the principal officers ſhall have leave for a few days to go where they pleaſe to ſettle their affairs.

6. When the garriſon quits the place, no attempts ſhall be made to debauch the ſoldiers, or to encourage them to deſert from their regiments.

When the capitulation is ſettled and ſigned, an officer of artillery from the beſiegers comes into the place, who, with an officer of artillery from the garriſon, takes an inventory of all the ordnance and ammunition in it; and commiſſaries, in like manner, take an account of all the proviſions.

The beſieged may deſtroy magazines before, but not after they have made any propoſition for a capitulation.

When the day arrives on which the garriſon is to leave the place, the army of the beſiegers is put under arms, and ranged in two files, between which the garriſon marches. The general and the principal officers head the two files, to ſee the garriſon defile before them.

The governor or commandant marches at the head, followed by the principal officers, who make the garriſon march in as good order as poſſible. The oldeſt regiments are commonly in the van and in the rear, and the others, with the baggage, in the centre. When there are any horſe or cavalry, they are alſo divided into three bodies, to march as the van, centre, and rear. Small detachments of horſe and foot are made to march at the ſides of the baggage, to prevent its being rifled.

The artillery allowed by the capitulation march after the firſt battalion.

When the garriſon arrives at the place agreed on, the governor gives up the hoſtages of the beſiegers to the eſcort; and when the eſcort reaches the army, the hoſtages left by the beſieged for the ſecurity of the eſcort, carriages, and other things allowed to them, are releaſed.

When the garriſon are made priſoners of war, they are in like manner eſcorted to the place agreed on.

Every thing ſtipulated or agreed upon in a capitulation ſhould be held ſacred and inviolable, and ought to be religiouſly obſerved. For when the king grants and ſigns a capitulation by his general, he acts in the ſame capacity as when he enters into and concludes a treaty of peace by his ambaſſador; in either caſe he acts as the procurator or agent of the community at large, as the conſtitutional repreſentative of parliament and the nation, and every ſuch act of his is equally binding on both. It is evident that parliament thought ſo when it paſſed the act that eſtabliſhed the church of Rome at Quebec and in Canada, and was convinced that it could not conſtitutionally violate the ſtipulations made in favour of that religion in the capitulation entered into by general Amherſt and the marquis de Vandreuil.

When the ſurrendering place or city has a citadel, it ſhould be ſtipulated that the garriſon ſhall have a certain time allowed them for retiring into the citadel with what they want; that the ſick and wounded, who are not in a ſituation to be removed, ſhall remain in their lodgings in the place till they are cured or get well, when they are to be furniſhed with carriages and paſſports to retire to ſome place agreed on; that none are to be admitted into the citadel that cannot be uſeful in aſſiſting to defend it; and that the beſiegers ſhall not erect any work or works whatſoever for the purpoſe of carrying on approaches againſt the ſame during the time preſcribed.

If the operations, either of the beſieged or beſiegers, be carried on in conjunction with confederates or allies, ſtipulations ought to be made on and in their behalf; and if they be principals as well as the beſiegers, they ſhould be parties to the capitulation.

If the place be a maritime town, with a harbour or harbours, and ſhipping in them, belonging either to the beſieged or to their allies, or other nations, terms or conditions reſpecting theſe ſhould be expreſsly inſerted in the body of the treaty or convention.

If the beſieged be in a place that is ſituate in a country diſtant from their own, to which they cannot return but by water, and have no other ſtrong hold in that country for them to retire to, they ſhould take care to have it ſtipulated in the capitulation that the beſiegers ſhall furniſh them with tranſports, proviſions, and a ſufficient convoy, and carry them to the neareſt port or ports in their own country.

As the capitulation agreed to and ſigned by lord Keith, lord Hutchinſon, Huſſem capitan pacha, and general Menou, at Alexandria the 30th Auguſt 1801, compriſes as great a diverſity of the foregoing ſpecified conditions or ſtipulations as any other that we know of, we will conclude this article by inſerting it as a very good ſpecimen, form, or model.

# CAPITULATION.

*Articles of the Capitulation propoſed by Abdoullah Jacques Francois Menou, General in Chief of the French Army now in Alexandria, to the Generals commanding the Land and Sea Forces of His Britannic Majeſty, and of the Sublime Porte, forming the Blockade of Alexandria, dated the 12th Fructidor, Year Nine of the French Republic, (30th of Auguſt,* 1801.)

Art. 1. From the preſent date to the 30th Fructidor (17th of September, 1801), there ſhall be a continuation of the truce and ſuſpenſion of arms between the French army, and the combined armies of his Britannic majeſty and of the Sublime Porte, upon the ſame conditions with thoſe which actually ſubſiſt, with the exception of a regulation to be amicably ſettled between the reſpective generals of the two armies, for eſtabliſhing a new line of advanced poſts, in order to remove all pretext of hoſtility between the troops.

Anſwer. Refuſed.

Art. 2. In caſe no adequate ſuccour ſhould arrive to the French army before the day mentioned in the preceding article, that army ſhall evacuate the forts and entrenched camps of Alexandria upon the following conditions.

Anſwer. Refuſed.

Art. 3. The French army ſhall retire, on the firſt complementary day of the French æra, into the city of Alexandria, and forts adjacent, and ſhall deliver up to the allied powers the entrenched camp in front of the lines of the Arabs, the Fort le Turc, and the Fort du Vivier, together with their artillery and ammunition.

Anſwer. In forty-eight hours after the ſigning of the capitulation, namely, on the 2d of September, at noon, the entrenched camp, the Fort Turc, and that of du Vivier, ſhall be delivered up to the allied powers. The ammunition and artillery of theſe forts ſhall be alſo delivered up. The French troops ſhall evacuate the city, forts, and dependencies of Alexandria ten days after ſigning the capitulation, or at the time of their embarkation.

Art. 4. All individuals, conſtituting a part of the French army, or attached to it by any relations, civil or military, the auxiliary troops of every nation, country, or religion, of whatever powers they might have been ſubjects before the arrival of the French, ſhall preſerve their property of every deſcription, their effects, papers, &c. &c. which ſhall not be ſubject to any examination.

Anſwer. Granted; provided that nothing be carried away belonging to the government of the French republic; but only the effects, baggage, and other articles belonging to the French and auxiliary ſoldiers who have ſerved during ſix months in the army of the republic; the ſame is to be underſtood of all the individuals attached to the French army, by civil or military capacities, of whatever nation, country, or religion they may be.

Art. 5. The French forces, the auxiliary troops, and all the individuals deſcribed in the preceding article, ſhall be embarked in the ports of Alexandria, between the 5th and the 10th of Vendemaire, year ten of the republic, at the lateſt (27th of September to the 3d of October, 1801), together with their arms, ſtores, baggage, effects, and property of all kinds, official papers, and depoſits, one field piece to each battalion and ſquadron, with ammunition, &c. &c. &c. the whole to be conveyed to one of the ports of the French republic in the Mediterranean, to be determined by the general in chief of the French army.

Anſwer. The French forces, the auxiliary troops, and all the individuals deſcribed in the 4th article, ſhall be embarked in the ports of Alexandria (unleſs after an amicable convention it ſhould be found more expeditious to embark a part of them at Aboukir), as ſoon as veſſels can be prepared, the allied powers at the ſame time engaging that the embarkation ſhall take place, if poſſible, ten days after the capitulation ſhall be ſigned; they ſhall receive all the honours of war, ſhall carry away their arms and baggage, ſhall not be priſoners of war, and ſhall moreover take with them ten pieces of cannon, from four to eight pounders, with ten rounds of ſhot to each gun; they ſhall be conveyed to a French port in the Mediterranean

Art. 6. The French ſhips of war, with their full complement, and all merchant ſhips, to whatever nation or individuals they may belong, even thoſe of nations at war with the allied powers, or thoſe that are the property of owners or merchants, who were ſubjects of the allied powers before the arrival of the French, ſhall depart with the French army, in order that thoſe that are ſhips of war may be reſtored to the French government, and the merchant ſhips to their owners, or to their aſſignees.

Anſwer. Refuſed. All veſſels ſhall be delivered up as they are.

Art. 7. Every ſingle ſhip that, from the preſent day to the 30th Fructidor, ſhall arrive from the French republic, or any of her allies, into the ports or roads of Alexandria, ſhall be comprehended in this capitulation. Every ſhip of war or commerce, belonging to France, or to the allies of the Republic, that ſhall arrive in the port or road of Alexandria within the twenty days immediately following the evacuation of that place, ſhall not be conſidered as lawful prize, but ſhall be ſet at liberty, with her equipage and cargo, and be furniſhed with a paſſport from the allied powers.

Anſwer. Refuſed.

Art. 8. The French and auxiliary troops, the civil and military agents, attached to the army, and all other individuals deſcribed in the preceding articles, ſhall be embarked on board ſome French or other veſſels, actually in the ports of Alexandria, as ſhall be in a condition to go to ſea, or on board thoſe of his Britannic majeſty, and of the Sublime Porte, within the time fixed by the 5th article.

Art. 9. Commiſſioners ſhall be named by each party to regulate the number of veſſels to be employed, the number of men to be embarked upon them, and generally to provide for all the difficulties that may ariſe in carrying into execution the preſent capitulation. Thoſe commiſſioners ſhall agree upon the different poſitions which ſhall be taken by the ſhips now in the port of Alexandria, and thoſe which ſhall be furniſhed by the allied powers, ſo that by a well-regulated arrangement, every occaſion of difference between the crews of the ſeveral nations may be avoided.

Anſwer. All theſe details will be regulated by the Engliſh admiral, and by an officer of the French navy, named by the general in chief.

Art. 10. Merchants and owners of ſhips, of whatever nation or religion they may be, and alſo the inhabitants of Egypt, and of every other country, who may at the preſent time be in Alexandria, whether Syrians, Cophts, Greeks, Arabs, Jews, &c. and who ſhall be deſirous of following the French army, ſhall be embarked with, and enjoy the ſame advantage with that army; they ſhall be at liberty to remove their property of all kinds, and to leave power for the diſpoſal of what they may not be able to take away. All arrangements, all ſales, all ſtipulations, whether of commerce or of any other nature made by them, ſhall be ſtrictly carried into effect after their departure, and be maintained by the generals of his Britannic majeſty, and of the Sublime Porte. Thoſe who may prefer remaining in Egypt a certain time, on account of their private affairs, ſhall be at liberty ſo to do, and ſhall have full protection from the allied powers; thoſe alſo who may be deſirous of eſtabliſhing themſelves in Egypt, ſhall be entitled to all the privileges and rights of which they were in poſſeſſion before the arrival of the French.

Anſwer. Every article of merchandize, whether in the town of Alexandria, or on board the veſſels that are in the ports, ſhall be proviſionally at the diſpoſition of the allied powers; but ſubject to ſuch definitive regulation as may be determined by eſtabliſhed uſage, and the law of nations. Private merchants ſhall be at liberty to follow the French army, or they may remain in the country in ſecurity.

Art. 11. None of the inhabitants of Egypt, or of any other nation or religion, ſhall be called to account for their conduct during the period of the French troops having been in the country, particularly for having taken arms in their favour, or having been employed by them.

Anſwer. Granted.

Art. 12. The troops, and all others who may be embarked with them, ſhall be fed during their paſſage, and until their arrival in France, at the expence of the allied powers, and conformably to the rules of the French navy. The allied powers ſhall ſupply every thing that may be neceſſary for the embarkation.

Anſwer. The troops, and all others who may be embarked with them, ſhall be fed during their paſſage, and until their arrival in France, at the expence of the allied powers, according to the uſage eſtabliſhed in the marine of England.

Art. 13. The conſuls and all other public agents, of the ſeveral powers in alliance with the French republic, ſhall continue in the enjoyment of all the privileges and rights which are granted by civilized nations to diplomatic agents. Their property, all their effects and papers, ſhall be reſpected, and placed under the protection of the allied powers: they ſhall be at liberty to retire or to remain, as they may think fit.

Anſwer. The conſuls and all other public agents of the powers in alliance with the French republic, ſhall be at liberty to remain or to retire, as they may judge fit. Their property and effects of any kind, together with their papers, ſhall be preſerved for them, provided they conduct themſelves with loyalty, and conformably to the law of nations.

Art. 14. The ſick who may be judged by the medical ſtaff of the army to be in a ſtate for removal, ſhall be embarked at the ſame time with the army, upon hoſpital ſhips properly furniſhed with medicines, proviſions, and every other ſtore that may be neceſſary for their ſituation; and they ſhall be attended with French ſurgeons. Thoſe of the ſick who may not be in a condition to undertake the voyage, ſhall be delivered over to the care and humanity of the allied powers. French phyſicians and other medical aſſiſtance ſhall be left for their care, to be maintained at the expence of the allied powers, who ſhall ſend them to France as ſoon as their ſtate of health will permit, together with any thing belonging to them, in the ſame manner as has been propoſed for the reſt of the army.

Anſwer. Granted. The ſhips deſtined for hoſpitals ſhall be prepared for the reception of thoſe who may fall ſick during the paſſage. The medical ſtaff of the two armies ſhall concert together in what manner to diſpoſe of thoſe of the ſick, who, having contagious diſorders, ought not to have communication with the others.

Art. 15. Horſe tranſports for conveying ſixty horſes, with every thing neceſſary for their ſubſiſtence during the paſſage, ſhall be furniſhed.

Anſwer. Granted.

Art. 16. The individuals compoſing the Inſtitute of Egypt, and the commiſſion of arts, ſhall carry with them all the papers, plans, memoirs, collections of natural hiſtory, and all the monuments of art and antiquity, collected by them in Egypt.

Anſwer. The members of the Inſtitute may carry with them all the inſtruments of arts and ſcience, which they have brought from France; but the Arabian manuſcripts, the ſtatues, and other collections which have been made for the French republic, ſhall be conſidered as public property, and ſubject to the diſpoſal of the generals of the combined army.

General Hope having declared, in conſequence of ſome obſervations of the commander in chief of the French army, that he could make no alteration in this article, it has been agreed that a reference thereupon ſhould be made to the commander in chief of the combined army.

Art. 17. The veſſels which ſhall be employed in conveying the French and auxiliary army, as well as the different perſons who ſhall accompany it, ſhall be eſcorted by ſhips of war belonging to the allied powers, who formally engage that they ſhall not in any manner, be moleſted during their voyage; the ſafety of ſuch of theſe veſſels as may be ſeparated by ſtreſs of weather, or other accidents, ſhall be guaranteed by the generals of the allied powers; the veſſels conveying the French army ſhall not, under any pretence, touch at any other than the French coaſt, except in caſe of abſolute neceſſity.

Anſwer. Granted. The commander in chief of the French army entering into a reciprocal engagement that none of theſe veſſels ſhall be moleſted during their ſtay in France, or on their return; he equally engaging that they ſhall be furniſhed with every thing which may be neceſſary, according to the conſtant practice of European powers.

Art. 18. At the time of giving up the camps and forts according to the terms of the third article, the priſoners in Egypt ſhall be reſpectively given up on both ſides.

Anſwer. Granted.

Art. 19. Commiſſioners ſhall be named to receive the artillery of the place and of the forts, ſtores, magazines, plans, and other articles that the French leave to the allied powers; and liſts and inventories ſhall be made out, ſigned by the commiſſaries of the different powers, according as the forts and magazines ſhall be given up to the allied powers.

Anſwer. Granted. Provided that all the plans of the city and forts of Alexandria, as well as all maps of the country, ſhall be delivered up to the Engliſh commiſſary. The batteries, ciſterns, and other public buildings, ſhall alſo be given up in the condition in which they actually are.

Art. 20. A paſſport ſhall be granted to a French armed veſſel, in order to convey to Toulon, immediately after the camps and forts before-mentioned ſhall be given up, officers charged by the commander in chief to carry to his government the preſent capitulation.

Anſwer. Granted. But if it is a French veſſel it ſhall not be armed.

Art. 21. On giving up the camps and forts mentioned in the preceding articles, hoſtages ſhall be given on both ſides, in order to guarantee the execution of the preſent treaty. They ſhall be choſen from among the officers of rank in the reſpective armies: namely, four from the French army, two from the Britiſh troops, and two from the troops of the Sublime Porte. The four French hoſtages ſhall be embarked on board the Engliſh ſhip, commanding the ſquadron; and the four Britiſh and Turkiſh hoſtages on board one of the veſſels which ſhall carry the commander in chief, or the lieutenant generals. They ſhall all be reciprocally delivered up on their arrival in France.

Anſwer. There ſhall be placed in the hands of the commander in chief of the French army, four officers of rank as hoſtages: namely, one officer of the navy, one officer of the Britiſh army, and two officers of the Turkiſh army. The commander in chief ſhall, in like manner, place in the hands of the commander in chief of the Britiſh army four officers of rank. The hoſtages ſhall be reſtored on both ſides at the period of the embarkation.

Art. 22. If any difficulties ſhould ariſe during the execution of the preſent capitulation, they ſhall be amicably ſettled by the commiſſaries of the armies.

Anſwer. Granted.

(Signed) Keith, Admiral.
J. Hely Hutchinson, Lieutenant General, Commander in Chief.
Hussim, Capitan Pacha.
Abdoullah Jacques Francois Menou, General in Chief of the French Army.
James Kempt, Lieutenant Colonel and Secretary.

Capitulation denotes alſo a kind of treaty, *pacta conventa*, or original contract, drawn up by the electors, in the name of the princes and ſtates of the empire, before the election of an emperor; which the emperor is to ratify before his coronation; and to obſerve inviolable in the courſe of his reign.

The imperial capitulations have only been obtained ſince the time of Charles V. before which time the ordinary conſtitutions of the empire ſerved in lieu of theſe capitulations. They were occaſioned by the jealouſy the German princes had entertained of the too great power of the emperor. Frederic, duke of Saxony, ſurnamed the Wiſe, paſſes for the author of the imperial capitulation; who, declining the empire, which was offered him after the death of Maximilian, adviſed the electors to chooſe Charles V. under ſuch conditions as might ſecure the liberty of the empire. The deſign of the capitulation is, on the one hand, to prevent the emperor from abuſing his power to the oppreſſion of the people; and, on the other, to prevent the people from breaking in on the juſt rights of the emperor. And the principal points which the emperor undertakes to obſerve are the defence of the church and empire, an obſervance of the fundamental laws of the empire, and a maintenance and preſervation of the rights, privileges, and immunities of the electors, princes, and other ſtates of the empire, ſpecified in the capitulation. The imperial capitulations are conſidered as fundamental laws of the empire; and though the drawing up, preſenting, procuring the ſignature, and taking care of the execution of them, be committed to the electors, they are reputed the act of the ſtates of the empire.

The king of the Romans alſo, when elected, ſigns the emperor's capitulation, as being in right of ſuch election to ſucceed to the empire after the death of the emperor.

CAPITULUM, in *Anatomy*, a little head, eſpecially of a bone, anſwering to the Greek *condylus*.

Capitulum, in *Botany*, the head, or compound flower of any plant; being compoſed of many leaves and threads or ſtamina, cloſely connected in a globoſe, circular or diſcous figure; as the flowers of bluebottles, ſcabious, carduus, &c.

Capitulum, in *Ancient Geography*, a town of Italy, ſituated in the mountains above Preneſte, in the country of the Hernici, according to Strabo. Pliny calls it "Capitulum Hernicum," and Frontinus "Capitolum," and ſays that it received a colony conformably to the law of Sylla.

Capitulum, in the *Ancient Military Art*, was a tranſverſe beam, wherein were holes through which paſſed the ſtrings whereby the arms of huge engines, as baliſtæ, catapultæ, and ſcorpions, were played or worked. Vitruv. de Arch. lib. i. cap. i.

Capitulum, in *Eccleſiaſtical Writers*, denoted part of a chapter of the Bible read and explained.

In which ſenſe they ſaid, *ire ad capitulum*, *to go to ſuch a lecture*. Afterwards the place or apartment where ſuch theological exerciſes were performed, was denominated *domus capituli*.

CAPITURIA, in *Ancient Geography*, a town of Thrace, ſituate in the country of mount Rhodope. Procopius.

CAPIVACCIO, Jerom, in *Medical Biography*, a native of Padua, where he arrived at the higheſt honours of his profeſſion. In what year he was born is not known, but probably about 1525. In 1552, having paſſed through the uſual degrees, he was made profeſſor in medicine, an office he continued to hold with credit upwards of 30 years, his lectures being always numerouſly attended. He was alſo in great requeſt as a practitioner, and particularly famed for his ſkill in curing the lues venerea, by which he is ſaid to have amaſſed a very large property. This accounts for his refuſing to remove to Piſa, though invited thither by the offer of a large ſalary by the grand duke of Tuſcany. He wrote on every branch of medicine; and, as moſt of his works paſſed through ſeveral editions, we may ſuppoſe not unſkilfully, though they are now generally ſuperſeded by newer opinions. He died in 1589. The titles of the principal of his works are, "De Lue Venerea Acroaſes," Spiræ, 1590. Francf. 1594, 8vo. He uſually began the cure with giving the decoction of guiacum and ſarſaparill; thoſe not ſucceeding, he had recourſe to mercurial inunction. "Methodus Practicæ Medicinæ, omnium Corporis Humani Adfectuum Cauſas, Signa, et Curationes exhibens," Ven. 1591, fol. "Methodus Anatomica, ſive Ars Conſecandi," edited by Teucer, with a diſſertation in praiſe of anatomy. A compendium, containing deſcriptions of all the parts of the body, taken from Galen. Venet. 1593. Alſo, "De Fœtus Formatione, De Signis Virginitatis, de Urinis," &c. Theſe, with ſeveral other ſmaller pieces, were collected and publiſhed together under the title of "Opera Omnia," fol. Venet. 1597, reprinted 1601-3, 6, and 17. Aſtruc De Morb. Ven. Douglas Bib. and Haller Bib. Med. Anat. et Chirurg.

A malignant and fatal fever raging at Venice in 1576, Capivaccio was ſent for to give his aſſiſtance in repreſſing it. But his endeavours not proving ſucceſsful, and having unfortunately on his arrival declared the fever not to be contagious, he was ſent away in diſgrace. More than 100,000 of the inhabitants are ſaid to have been ſwept off by the fever.

CAPIVARD, in *Zoology*. See Capybara.

CAPIVI. See Balsam.

CAPNELÆON, from καπνος, *ſmoke*, and ελαιον, *oil*, among *Ancient Naturaliſts*, denotes a ſpecies of reſin, which flows ſpontaneouſly, being warmer, thinner, and more fluid than all other ſorts of reſins, ſo as nearly to approach the nature of oil, and evaporating plentifully on being expoſed to the fire; whence the denomination, which imports as much as ſmoaking oil. It is ſometimes alſo called *piſſanthos*, or flower of pitch.

CAPNIA, in *Botany*, (from καπνια, *ſoot*,) a genus formed by Ventenat for the umbilicated lichens of Linnæus.

CAPNICON, in *Antiquity*, chimney-money, or a tax which the Roman emperors levied for ſmoke, and which of conſequence was due from all, even the pooreſt, who kept a fire. This was firſt invented by Nicephorus.

CAPNIO, in *Biography*. See Reuchlin.

CAPNISTON, among *Ancient Phyſicians*, denotes oil whoſe fumes, rendered aromatic by burning ſpices, are conveyed to a part affected.

CAPNITIS, or Capnitas *Jaſpis*, in the *Natural Hiſtory of the Ancients*, the name of a ſpecies of chalcedony, of a browniſh ground, clouded with a large miſt of blackiſh, looking like a column of ſmoke. The ancients alſo called our common chalcedony a jaſper, not allotting any peculiar generical name to theſe miſty ſtones; and the name they gave this ſpecies very happily expreſſed its character, becauſe it looks exactly as if obſcured by a cloud of thick ſmoke. It is very common in the Eaſt Indies, and is ſometimes found in Germany and France, but is ſeldom worked into any thing better than knife-hafts. See Chalcedony.

CAPNOIDES, in *Botany*. (Tourn. and Gærtner.) See Fumaria, Capnoides, and Lutea.

CAPNOMANCY, a kind of divination by means of ſmoke, uſed by the ancients in their ſacrifices. The word comes from καπνος, *ſmoke*, and μαντεια, *divination*. The general rule was, when the ſmoke was thin and light, and roſe ſtraight up, it was a good omen; if the contrary, it was an ill one.

There was alſo another ſpecies of capnomancy, conſiſting in the obſervation of the ſmoke riſing from poppy and jeſſamin-ſeeds caſt upon light coals.

CAPNOPHYLLUM, in *Botany*, a genus formed by Gærtner for the *Conium Africanum* of Linnæus, with the following character. *Umbel* compound, conſiſting of few rays; lateral rays of the partial umbel barren; central one very ſhort, fertile. *Involucres* very ſhort, each conſiſting of about three leaves. *Corolla* irregular. *Fruit* nearly ſeſſile; ridges muricated with tubercles. See Conium *Africanum*.

CAPNOS, (Lobel). See Fumaria *officinalis*, and *ſpicata*.

CAPO, in *Ichthyology*, a name given by Paulus Jovius and ſome others to the fiſh called *coccyx* by the ancient Greeks, and *cuculus* by the Latin writers. It is preſumed to be a ſpecies of *trigla*, moſt likely the modern *trigla gurnardus*; or, perhaps, applied indiſcriminately to that ſpecies, and *trigla lyra*.

Capo, *Ital.* the head, or beginning of any production. In vocal muſic, particularly in opera ſongs of two ſtrains, *da capo*, at the end of the ſecond ſtrain, is an injunction to return to the beginning of the air or movement, or to any part of it where this character of reference 𝄋, can be diſcovered, and purſue its courſe as far as this ſign 𝄐, which is placed over the finale note. See Segno and Corona.

Capo-Bianco, in *Geography*, a canton of the department of Golo, or iſle of Corſica, containing 4147 inhabitants.

Capo *d'Iſtria*, a ſea-port town of Iſtria, belonging to the ſtate of Venice, the ſee of a biſhop, ſuffragan of Udina, ſituate in the gulf of Trieſte, in an unhealthy diſtrict, near ſalt marſhes; 7 miles S. of Trieſte. N. lat. 45° 48'. E. long. 14°.

CAPOC, in *Commerce*, a ſort of cotton, ſo fine and ſo ſhort, that it cannot be ſpun. It is uſed in the Eaſt Indies to line palanquins, to make beds, mattreſſes, cuſhions, pillows, &c.

CAPOETA, in *Ichthyology*, a ſpecies of Cyprinus, inhabiting the Caſpian Sea, and in winter migrating up the rivers. The anal fin has nine rays, the third ray of the dorſal and anal being the longeſt, and ſerrated downwards; and it has two cirrhi. Gmelin.

COPOLETTO, a town and port of Aſia, in Georgia, ſeated on the Black Sea.

CAPOLINIERI, a ſmall town of the iſland of Elba, near the coaſt of Tuſcany.

CAPOLITA, in *Geography*, a river of North America, in the province of Guaxaca, which runs into the Pacific Ocean, 18 miles N. E. of Tangolotargo.

CAPOLLIN, in *Botany*, *Mexicanorum Hernandez*, *ſeu Cerafus dulcis Indica*. It is a tree of moderate bigneſs, with leaves like thoſe of an almond, or our country cherry tree. The flowers hang down in bunches, which are ſucceeded by fruit reſembling our cherries. It bloſſoms in the ſpring, and bears fruit all the ſummer; it requires a temperate climate, and grows in gardens and fields in Mexico, as well ſpontaneouſly as by cultivation.

The juice of the young buds mollifies the tongue when parched by heat. A decoction of the bark being expoſed to the ſun for fifteen days, and the weight of a dram of it taken, cures the dyſentery. The powder helps inflammations. In times of dearth, they make bread and drink of the fruit; but it affords an aliment inclining to melancholy, giving a rankneſs to the breath, and making the teeth black. There are three ſpecies of this tree, which differ only in fruit; but all of them hang in cluſters.

CAPON, in *Rural Economy*, a cock chicken, which has been caſtrated as ſoon as left by the hen, or as ſoon as he begins to crow. Capons are uſeful to lead chickens, ducklings, young turkeys, pheaſants, or partridges, as they do it better than hens, and at the ſame time defend them better from birds of prey, and, from the largeneſs of their bodies, they can cover a greater number of them, and much more completely. See Poultry.

Capon's *Tail-graſs*. See Festuca.

CAPONIER, in French Caponiere, or Caponniere, a ſort of double covert-way, with a parapet on each ſide, ſloping, and terminating in the form of a glacis. All communications of this ſort and form, between either the body of the place and the outworks, or between the ſaliant angles of the covert-way, and either arrows or other works at the ſaliant angles of the glacis, or between the ſaliant angles of the covert-way, and detatched redoubts, or works advanced to ſome diſtance beyond the glacis, for the purpoſe of occupying particular ſpots of ground, to prevent an enemy's getting poſſeſſion of them, may with propriety be, and ſometimes are, called *caponiers*.

When the communication is directly oppoſite to the middle of the curtain, and extends from the tenailles acroſs a dry ditch to the re-entering angle of the counter-ſcarp, or of the ravelin, it is from twelve to fifteen feet wide, has a banquette on each ſide, as alſo a parapet, which terminates in the ditch in a gentle ſlope, in the form of a glacis, at the diſtance of ten or twelve fathoms from its interior ſide. The inſide of it is excavated from two to four feet below the level of the ditch, and the parapet is raiſed from three to five feet above the ſame level. It ſerves as a ſafe paſſage for the troops from the body of the place to the counter-ſcarp and outworks. Such caponiers are frequently made in dry ditches, even when there are no tenailles oppoſite to the curtains.

The principal uſe of ſuch caponiers is to defend, directly, the paſſage of the ditch oppoſite to the faces of the baſtions, and to afford the ſoldiers a ſecure communication between the body of the place and the outworks. To prevent their being ſeen, as they are quitting or leaving them, the re-entering angles of the counter-ſcarp are often partly cut off by right lines parallel to the curtains and excavations, or lodgments are made in thoſe places, ſometimes in one form and ſometimes in another.

When ſuch a communication is made between a ſaliant angle of the covert-way and a work on one at the foot of the glacis, it is commonly from twenty four to thirty feet wide, and has a traverſe at its entrance, about eighteen feet thick, with a paſſage ſix or eight feet wide round it.

When ſuch a communication is made from a ſaliant angle of the covert-way to a detached redoubt, or other work, advanced beyond the foot of the glacis, it is uſually from thirty to thirty-ſix feet wide; and when it is of any conſiderable length, has commonly two traverſes, one at its entrance, and the other in the middle, or about half way between the work and the foot of the glacis.

It was the cuſtom formerly to cover the caponier with thick planks, and a quantity of earth upon them, and to open ſmall embrazures or loop-holes in each parapet, for firing through on the enemy. But the ſmoke of the powder occaſioned great annoyance and inconvenience to the men in it. It is, therefore, cuſtomary now to cover them, during a ſiege, only with hurdles or blinds, ſufficiently to ſecure the men employed in defending them againſt ſtones, which the enemy may throw into the ditch to make them abandon it. The ſame nuiſance and inconvenience from ſmoke would be found to ariſe from the making uſe of fire-arms in ſuch caſemated galleries, with loop-holes in the counter-ſcarp, as thoſe in ſome of the works at Portſmouth. Other arms or offenſive weapons than fire-arms might, undoubtedly, be made uſe of in them, with much leſs inconvenience than muſkets, and at the ſame time with greater effect and certainty, at ſo ſhort a diſtance as the width of the ditch. See Fortification, *fig.* 18.

CAPORALE, in *Biography*, an Italian performer on the violoncello, who came into England about the year 1734, and was much admired for the full and ſweet tone which he drew from his inſtrument; which was his principal merit: for he was no deep muſician, nor had he a powerful hand; yet he was always heard with great partiality by the public, and Handel frequently compoſed ſongs expreſsly to diſplay his intelligible talent of tone.

CAPORALI, Cæsar, an Italian poet, was born at Perugia, in 1530, and having been ſucceſſively employed in the ſervice of ſeveral cardinals, died in 1601, at the ſeat of his patron Aſcanio, marquis of Cargno. As a poet in the bernieſque, or burleſque ſtyle, he excelled moſt of thoſe who wrote in the ſame ſtyle, particularly in decency of ſubject and imagery. His moſt popular piece was a ſatire on courts and courtiers, expoſing to ridicule and contempt thoſe who ſink into ſervility and wretchedneſs by aſpiring to fortunes in an attendance on the great. He wrote alſo ſome poems of the romantic claſs, as his "Life of Mecænas," left unfiniſhed, and two comedies, viz. "Lo Seiocco," and "La Ninnetta;" publiſhed at Venice in 1605. A collection of his poems, with the obſervations of his ſon, Charles, was publiſhed at Venice, in 1656 and 1662. Tiraboſchi. Moreri. Gen. Biog.

CAPORNACK, in *Geography*, a town and caſtle of Hungary, in Sclavonia.

CAPOT, at *Picquet*, is when one of the gameſters wins all the cards, in which caſe he gains forty points.

CAPO-TASTO, in *Muſic*, in high ſhifts on the violoncello, is ſhortening the ſtrings, by making the thumb of the left hand ſerve as a nut on the finger-board; by which means the four fingers can play as many paſſages without altering the poſition of the hand, as in its natural poſition, without ſhifting.

CAPOTENA, or Capotana, in *Ancient Geography*, a town of Aſia, placed by Ptolemy in Aſia.

CAPOTES, a mountain in Aſia, in which, according to Pliny, was one of the ſources of the Euphrates.

CA-POUDIA, the *Caput Vada* of Procopius, the *Ammonis Promontorium* of Strabo, and the *Promontorium Brachodes* of Ptolemy, a long narrow ſlip of land, ſtretching itſelf a great way into the ſea, on the weſtern coaſt of the ancient Bizacium, or Tunis. Upon the point of this promontory are the ruins of the city that was built there by Juſtinian; where is likewiſe a high round watch-tower. Two more of the like kind occur between this place and Sfax; which are neceſſary guides to mariners in approaching this low and dangerous coaſt. To the S.E. of Ca-poudia are the two flat and contiguous iſlands of the "Querkinoſs," the ancient "Circina," and "Circemitis," at the diſtance of five leagues. At theſe iſlands Strabo and other ancient geographers fix the beginning of the Leſſer Syrtis; though Dr. Shaw is of opinion, that it ſhould rather commence at Ca-poudia. N. lat. 35° 2′. E. long. 11° 30′.

CAPOUL, or Capul, one of the ſmaller Philippine iſlands, lying a little ſouth of Luçon. It is three leagues in compaſs; the ſoil is fertile, agreeable, and commodious for the Indians, who live after the manner of the Biſayas.

CAPOZWAR, a ſmall but ſtrong town of Hungary, ſeated on the river Capoz.

CAPPA, in *Ichthyology*, a ſpecies of Sciæna, having double ſcales on the ſides of the head. Found in the Mediterranean.

CAPPADINE, in *Commerce*, a ſort of ſilk flock, taken from the upper part of the ſilk-worm cod, after the true ſilk has been wound off. It is alſo called *laſſis* and *carbaſs*, becauſe ſlight ſtuffs under thoſe names are made of it.

CAPPADOCIA, in *Ancient Geography* and *Hiſtory*, was known to the ancients by the name of Syria or Aſſyria, and borrowed the name of Cappadocia, according to Pliny (l. vi. c. 3.) from the river Cappadox, or according to Herodian (apud Stephan.) from Cappadocus, the founder of this kingdom. In ancient times, this kingdom comprehended the whole of that country, which lies between mount Taurus and the Euxine ſea; and was divided by the Perſians into two ſatrapies, or governments; and by the Macedonians, under the ſucceſſors of Alexander, into two kingdoms; the one called "Cappadocia ad Taurum," and "Cappadocia Magna," the other "Cappadocia ad Pontum," and commonly "Pontus," which ſee.

*Cappadocia Magna*, or "Cappadocia" properly ſo called, lay between the 38th and 41ſt degrees of north latitude; bounded on the north by Pontus, from which it was ſeparated by a long chain of mountains, bearing towards the weſt the appellations of Lithrus and Ophlinus, and towards the eaſt that of Paryadræ; on the ſouth, by Lycaonia, and part of Armenia Minor; or, according to M. d'Anville, by mount Taurus, which ſeparated it from Comagena and Cilicia; on the weſt, by Galatia and Phrygia; and on the eaſt, by the Euphrates, and part of Armenia Minor, or, if it be made to compriſe this latter province, it is almoſt wholly bounded by the Euphrates, which ſeparated it from Sophena. In the time of Archelaus, Cappadocia was divided into ten prefectures, five of which lay near mount Taurus, viz. Melitena, Cataonia, Cilicia, Tyanitis, and Iſſauritis; and the other five comprehended the remaining part of the kingdom, of the ſituation and principal towns of which Strabo has given no information. According to Ptolemy Cappadocia, to which he alſo annexes Pontus, was bounded on the weſt by Galatia; on the ſouth by Cilicia, and part of Syria towards the Amanus; on the eaſt by Armenia Major and the Euphrates; and on the north by that part of the Euxine ſea, which extended from Amiſus in Galatia to the branch of the Amanus that bounded the country on the eaſt. The emperor Valens divided Cappadocia into two provinces, viz. Cappadocia Prima" and "Cappadocia Secunda," of which latter Tyana was the metropolis. The metropolis of Cappadocia, in ancient times, was Mazaca or Euſebia, called afterwards *Cæſarea*, which ſee. Its other cities of note were Comana, Nyſſa, Nazianzum, Archelais, Diocæſarea, Fauſtinopolis, Cabiſtra, and Pterium, which ſee reſpectively. The principal rivers of this country were the Melas, the Halys, and the Sarus.

Whatever may have been the national character of the Cappadocians at an early period and under their firſt ſovereigns, they were in the time of the Romans reputed laſcivious, lewd, and addicted to all manner of vice; and they were deemed ſo infamous among other nations, that a wicked and impious man was emphatically called a "Cappadocian." The following very ancient Greek epigram, applied to the Cappadocians, is recorded by Conſtantine Porphyrogenitus:

> "Καππαδόκην ποτ' ἔχιδνα κακὴ δάκεν, ἀλλά και αὐτὴ,
> Κάτθανε γευσαμένη αἵματος ἰοβόλου."
>
> "Cappadocem aliquando vipera mala momordit, ſed et ipſa
> Mortua eſt guſtato ſanguine virulento."

It was a nation ſo ſervile, ſays Strabo (l. xii. p. 372.), that when the Romans offered them their freedom to live by their own laws, they ſaid they could not endure liberty. Cicero ſays of them, that they were "De Grege Venalium;" whence it is inferred, that this country furniſhed a great number of ſlaves; ſee alſo Perſius Sat. vi. ſub fin. Horat. Ep. vi. l. i. v. 39. This national character, however, underwent an important change after the introduction of Chriſtianity; for we find among the natives of Cappadocia Gregory Thaumaturgus, Baſil the Great, and Gregory of Nazianzum.

The religion of the ancient Cappadocians was much the ſame with that of the Perſians. At Comana they had a rich and ſtately temple, conſecrated to Bellona, whoſe prieſts and attendants of both ſexes amounted, in Strabo's time, to more than 6000. On ſtated days they had exhibitions of battles, in which the prieſts and their attendants cut and wounded each other in a tranſport of enthuſiaſtic fury. They had alſo ſeveral other magnificent temples of Apollo Cataonius, and of Jupiter, in the province of Morimena, which laſt had 3000 religious votaries. The chief prieſt, next in rank to that of Comana, had, as Strabo ſays (l. xii. p. 375.), a yearly revenue of 15 talents. Diana Perſica was worſhipped in the city of Caſtaballa, where women, devoted to the worſhip of this goddeſs, are ſaid to have trodden barefooted on burning coals, without injury. The commerce of the Cappadocians in mules and horſes, produced in their country, was very conſiderable. The horſes that were bred on the plains, which ſtretched from the foot of mount Argæus to the banks of the Sarus, were renowned above all others in the ancient world, for their majeſtic ſhape and incomparable ſwiftneſs. Cappadocia abounded alſo with mines of ſilver, iron, and alum, and afforded alabaſter, cryſtal, and jaſper, and probably ſupplied the neighbouring countries with theſe commodities.

It has been thought by thoſe who have made reſearches into the hiſtory of ancient nations, that Cappadocia was peopled by the deſcendants of Togarmah, the youngeſt ſon of Gomer. In the time of Crœſus ſome have ſuppoſed that Cappadocia formed a part of the kingdom of Lydia; and after the defeat of this prince, it became ſubject to the Perſians, to whom the Cappadocians paid an annual tribute, as Strabo ſays (l. xii. p. 370.), of 1500 horſes, 2000 mules, and 50,000 ſheep. The moſt ancient king of Cappadocia, recorded in hiſtory, is Pharnaces, a noble Perſian, who, having ſaved Cyrus from a ravenous lion, that purſued him while he was hunting, was rewarded with his ſiſter Atoſſa, and the kingdom of Cappadocia. This country was afterwards ſubdued by the Macedonians, and changed into a province; but it was reſtored to its former ſtate by Ariarathes III., who, having eſcaped the general ſlaughter of the royal family by Perdiccas in the time of his father Ariarathes II., fled into Armenia; and availing himſelf of the civil diſſenſions that took place among the Macedonians, recovered his paternal kingdom, and tranſmitted it to his poſterity. After a ſucceſſion of 10 princes, Archelaus, though not related either to the family of Pharnaces or to that of Ariobarzanes, which had poſſeſſed the ſovereignity, was placed on the throne of Cappadocia by Mark Antony, to whom he continued faithful till after the battle of Actium. But having offended Tiberius by paying him no reſpect, during his retirement at Rhodes, he was enticed to Rome by letters from Livia, who, without diſſembling her ſon's reſentment, promiſed him his pardon, on condition of his coming to implore it in perſon. Archelaus obeyed the ſummons; but was received by the emperor with contempt and indignation, and ſoon after accuſed as a criminal in the ſenate. Although the crimes alleged againſt him were mere fictions, he was ſo chagrined at being treated like a malefactor, that he is ſaid by ſome to have ſoon died of grief, or, as others ſay (Tacit. Annal. lib. 1.), he laid violent hands on himſelf. Upon his death, the kingdom of Cappadocia was reduced to a Roman province, and governed by thoſe of the equeſtrian order. Germanicus, A. D. 18, regulated the affairs both of Cappadocia and Commagena, and appointed two of his friends to the government of theſe provinces. In the year 73, Veſpaſian ſent troops into Cappadocia and attached the government of that province to the rank of conſul, inſtead of the order of knights. In this ſtate Cappadocia continued till the erection of the new empire of Trebiſond, with which it fell into the hands of the Turks; by whom the whole province, with the addition of Pontus, is now called Amaſia, after the name of that city, where the beglerbeg of Anatolia reſides. See Amasia.

CAPPADOX, a river of Aſia, which has its ſource in mount Amanus, and diſcharges itſelf into the Euphrates S. E. of Samoſata.—Alſo, a river of Aſia which bounded the Cappadocians on the ſide of Galatia, and commencing to the eaſt of Saonda falls into the Halys at Aſpona. See Cappadocia.

CAPPAGUM, a town of Spain placed by Pliny in Bœtica.

CAPPANUS, in *Conchology*, the name by which ſome old writers diſtinguiſh the *ſea-worm*, or teſtaceous molluſca, called by recent authors *Teredo navalis*. This is alſo known by the name of ſhip-worm, being that particular ſpecies which bores into the bottoms of ſhips, and to obviate the pernicious effects of which they are now generally ſheeted with copper from the keel to a little above the water's edge.

CAPPAREA, in *Ancient Geography*, a town of Aſia, ſituate in a plain of Syria, S. E. of Apamea.

CAPPARIDES, or Capparideæ, in *Botany*, the fourth order of the thirteenth claſs of Juſſieu's natural orders, and the eighth order of the thirteenth claſs in the arrangement of Ventenat; with the following characters. *Calyx* either many-leafed, or one-leafed divided into ſegments. *Petals* four or five, often alternating with the diviſions of the calyx. *Stamens* ſeldom of a definite number. *Germ* ſimple, often ſtipitate or pedicelled; ſtipe or pedicel ſometimes ſtameniferous and glandular at its baſe; ſtyle none, or rarely one; ſtigma ſimple. *Fruit* many-ſeeded, either a ſilique or a berry, one-celled (rarely many-celled?). *Seeds* often kidney-ſhaped, either bedded in the pulp of the fruit, or affixed to lateral receptacles. *Periſperm* none, though the interior coat of the ſeed is ſometimes fleſhy and ſwollen ſo as to appear like a periſperm. *Embrio* ſemicircular; radicle curved upon the lobes which are almoſt cylindrical, and applied one to the other. See Ventenat Pl. 15. fig. 3. *Stem* almoſt always a ſhrub or tree, rarely herbaceous. *Leaves* alternate, ſimple, entire, rarely ternate or digitate, proceeding from naked, ſcaleleſs buds; ſometimes with two ſtipules, ſpines or glands at their baſe. Its genera, according to Juſſieu, are cleome, cadaba, capparis, ſodaba, crateva, moriſonia, and durio; the following are added as nearly allied, margraſia, norantea, reſeda, droſera, and parnaſſia. Ventenat deſcribes under this order only cleome, capparis, crateva, and moriſonia; reſeda and parnaſſia as nearly allied.

CAPPARIS, (καππαρις, Theophraſ. Dioſcorides; derivation uncertain. Some ſuppoſe it originally Arabic.) Linn. gen. 643. Schreb. 876. Willd. 1010. Juſſ. 243. Vent. 2. 120. Tourn. 139. Claſs and order, *polyandria monogynia.* Nat. Ord. *putamineæ*, Linn. *capparides*, Juſſ. Gen. Ch. *Cal.* Perianth four-leafed or four-cleft, leathery; leaves or ſegments egg-ſhaped, concave, gibbous, caducous. *Pet.* four, obtuſe, ſpreading, generally large. *Stam.* Filaments generally numerous, thread-ſhaped, ſpreading; anthers oblong, verſatile, inclined. *Piſt.* Germ pedicelled; ſtyle none; ſtigma obtuſe. *Peric.* Berry, capſule or ſilique, fleſhy, various in ſhape, one-celled, pedicelled. *Seeds* generally numerous, kidney-ſhaped.

Eſſ. Ch. *Calyx* four-leaved or four-cleft; leathery. *Petals* four, ſtamens long. *Pericarp* fleſhy, one-celled, pedicelled. Obſ. C. cantonienſis has a five-leaved calyx and five petals.

* *With ſpiny ſtipules.*

Sp. 1. C. *ſpinoſa*, caper-buſh, Linn. Sp. Pl. 1. Willd. 1. Lam. Encyc. 1. Martyn's Miller 1. Smith ſpicil. 2. 18. tab. 20. Lam. Ill. Pl. 446. Woodv. Med. Bot. Pl. 228. Curtis Bot. Mag. 291. "Peduncles one-flowered, ſolitary; leaves roundiſh, obtuſe, ſmooth; capſules oval," Willd. A low ſhrub, generally growing out of the joints of old walls, the fiſſures of rocks, and among rubbiſh. *Stems* trailing two or three feet long, round, ſmooth, branched; branches alternate, ſpreading, often downy. *Leaves* on ſhort petioles, alternate, in the wild plant often terminated by a little ſharp point which diſappears by culture, entire, a little fleſhy, veiny, ſmooth, bright green; ſpiny ſtipules two, ſharp, a little recurved, yellowiſh, in the cultivated plant nearly obliterated. *Flowers* large, beautiful, ſcentleſs; peduncles axillary, round, about the length of the leaves, firſt horizontal, finally pendulous,; calyx-leaves unequal, tipped with purple; petals white, with a faint tincture of red, larger than the calyx, ſpreading, inverſely egg-ſhaped, waved; the two upper ones a little cohering at their baſe; ſtamens very numerous, the length of the petals or longer; filaments pale purple; germ oval, ſmall, green; pedicel purpliſh, longer than the ſtamens. *Fruit*, according to Linnæus, a berry; Dr. Smith, a capſule; La Marck, a ſilique; but it is evident from his figure that he has given it an improper denomination. Suppoſed to have been originally a native of Aſia, but from long cultivation naturalized in the ſouthern parts of Europe. Dr. Smith ſays that it is as common in the South of France as the bramble with us. Mr. Ray obſerved it wild on the walls of Rome, Sienna, and Florence. Between Marſeilles and Toulon and in many parts of Italy it is cultivated on a large ſcale for the ſake of the young buds of the flowers which are pickled for the table and exported in conſiderable quantities. The plants are raiſed from ſuckers ſet in a quincunx form about ten feet diſtant from each other. They require ſhelter from cold winds and a favourable expoſure to the ſun, and ſcarcely ever ſuffer from drought and heat. In ſpring, they need only one dreſſing; in autumn they are cut down to within ſix inches of the ground and covered with the ſurrounding earth, which is raiſed about them on all ſides. In the ſucceeding ſpring they are laid bare to the crown of the root and ſoon throw out young ſhoots. In an early part of the ſummer they begin to flower; and a ſucceſſion of them continues till they are deſtroyed by the cold of the advancing winter. The young buds of the flowers are carefully gathered every morning by women and children; for as they increaſe in ſize, they diminiſh in value. They are immediately thrown into veſſels full of vinegar with the addition of a little ſalt, and when a ſufficient quantity is collected, are ſold to the pickle merchants, who riddle them and diſtribute them in different parcels according to their ſize; then put them again in vinegar, and pack them up for ſale. The green fruit alſo, when it has attained to the ſize of an olive, makes a grateful pickle. Boſc. The pickled caper bud has the character of an antiſcorbutic, and of removing hepatic and other viſceral obſtructions; but the part of the plant which has chiefly been recommended for medicinal purpoſes is the bark of the root. Its taſte is ſomewhat aromatic, bitteriſh and acrid. By Dioſcorides and other ancient writers, it was thought of great efficacy as a deobſtruent, and in this view has been recommended by Foreſtus and Sennertus, but its uſe is now wholly laid aſide. Woodville. Though this plant, when trained againſt a wall, grows luxuriantly in the open air at Paris, it is preſerved with difficulty in England, and can ſcarcely be made to flower unleſs kept in a ſtove. 2. C. *ovata*, Willd. 2. Desfont. Fl. Att. 1. p. 404. (C. ſpinoſa, β. Linn. C. folio acuto; Bauh. pin. 460.) "Peduncles one-flowered, ſolitary; leaves roundiſh-egg-ſhaped, acute, ſmooth; capſules oval." A native of Sicily, Spain, and Barbary. According to Miller it is merely a variety of C. ſpinoſa. 3. C. *ægyptia*, Lam. Enc. 2. Willd. 3. "Peduncles ſolitary, one-flowered; leaves roundiſh-wedge-ſhaped, mucronate at the tip." Lam. A ſhrub. *Branches* ſtiff, ſlender, round, ſmooth, ſtipular ſpines two, crooked, gold-coloured. *Leaves* ſmall, about ſix lines long, and five at their greateſt breadth, glaucous, petioled. *Flowers* dull white; peduncle ſmooth, longer than the leaf. *Fruit* club-ſhaped, about three inches long and three lines thick. MSS. of Lipp. who obſerved it in Egypt, preſerved in the herbarium of Iſnard. 4. C. *tomentoſa*, Lam. Enc. 5. Willd. 4. (Cratæva Adanſ. Herb. Seneg. p. 41.) "Peduncles ſolitary; leaves oblong-egg-ſhaped, obtuſe, downy; ſiliques ſpherical." *Branches*, *leaves*, and *peduncles* covered with a ſhort, greyiſh, cottony down. *Stipular* ſpines two, crooked. *Leaves* about an inch and a half long, five or ſix lines broad, a little emarginate; petioles ſhort. *Flowers* axillary. Found by Adanſon in Senegal. 5. C. *pyrifolia*, Lam. Enc. 8. "Peduncles one-flowered, ſolitary, very ſhort; leaves lanceolate-egg-ſhaped, acuminate; younger ones downy." β. flowers faſciculated. A ſhrub. *Branches* ſlender, round, downy towards their ſummit; ſtipular ſpines two, ſhort, crooked. *Leaves* alternate, diſtant, petioled, three inches long, a little more than an inch broad. *Flowers* axillary; ſtamens very long. Found by Poivre in the Eaſt Indies, preſerved in the herbarium of Juſſieu. 6. C. *acuminata*, Willd. 5. "Peduncles in pairs, one-flowered; leaves egg-ſhaped, acuminate, covered underneath with a ruſt-coloured down." Willd. A ſhrub. *Branches* round, zigzag; ſtipular ſpines two, ſtraight. *Leaves* petioled, alternate. *Flowers* axillary, ſometimes three together; peduncles longer than the petioles; calyx downy; ſtamens longer than the corolla. A native of the Eaſt Indies, deſcribed from a dried ſpecimen by Willdenow, who doubts whether it differs ſpecifically from La Marck's *pyriſolia*. 7. C. *zeylanica*, Linn. Spec. 2. Willd. 6. Lam. 3. Mart. 2. Pet. Muſ. 625. Burm. Zeyl. 53. Ind. 118. Loureiro Cochinch. 330. "Peduncles ſolitary, one-flowered; leaves egg-ſhaped, acute at both ends." A ſhrub. *Stem* ſix feet high, upright, but weak; branches divaricating; ſpines two, ſmall, crooked. *Leaves* twice as long as broad, alternate, remote, entire, ſmooth on both ſides. *Flowers* axillary, ſometimes two together, white; petals oblong, ſpreading, nearly equal; with a lateral, prominent, cloven nectary; ſtamens thrice the length of the corolla. *Fruit* unknown to Linnæus. *Berry* black, roundiſh, fleſhy, ſmall, one-celled, with three ſeeds; peduncle long. Lour. A native of Ceylon and Cochinchina, in hedges. 8. C. *horrida*, Linn. jun. Sup. 264. Willd. 7. Mart. 3. Lam. 10. "Peduncles in pairs, one-flowered; leaves lanceolate-egg-ſhaped, mucronate, ſmooth." A tree. *Branches* ſtiff, zigzag; ſpines two, ſtrong, red. *Leaves* petioled. *Flowers* axillary. A native of the Eaſt Indies. 9. C. *erythrocarpus*, Willd. 8. Gmel. Syſt. 806. Iſert. Act. Soc. Berol. ix. p. 339. tab. 9. bad. "Peduncles ſolitary, one-flowered; leaves oblong, acuminate, mucronate; pericarps hexagonal." A ſhrub. *Branches* divaricated, round; ſtipular ſpines two, reflexed. *Leaves* alternate, petioled, ſmooth, beſet with ſtellated hairs here and there on the under ſurface, eſpecially on the midrib. *Flowers* axillary. *Fruit* red. A native of Guinea. 10. C. *divaricata*, Lam. 7. "Stem much branched, branches zigzag, divaricated; leaves linear, narrow, acute, nearly ſeſſile. Lam. A ſhrub, ſmooth in all its parts. *Branches* ſlender; ſpines two, ſhort, crooked. *Leaves* about an inch long, alternate, on very ſhort petioles. A native of the Eaſt Indies, preſerved in the herbarium of Juſſieu. Does it differ from the preceding? 11. C. *cantonienſis*, Mart. 18. Lour. Cochin. 331. "Flowers in racemes; leaves egg-ſhaped, acuminate, wrinkled." *Stem* ſhrubby, upright, branched. *Leaves* entire, ſmooth, alternate. *Flowers* white; calyx five-leaved; leaves oblong concave, coloured; petals five, oblong, ſpreading, the length of the calyx; filaments long. *Berry* egg-ſhaped, ſmall, brown, peduncled. *Seeds* numerous. A native of China about Canton. 12. C. *ſepiaria*, Linn. Sp. Pl. 3. Willd. 9. Mart. 4. Lam. 6. "Peduncles in umbels; leaves egg-ſhaped, emarginate." A ſhrub. *Branches* ſlender, round, zigzag, pubeſcent; ſpines two, crooked, ſhort, blackiſh at their ſummit. *Leaves* alternate, pubeſcent, on ſhort petioles. *Umbels* ſimple, terminal, many-flowered; common peduncles ſhort. A native of the Eaſt Indies. 13. C. *citrifolia*, Lam. 9. Willd 10. "Flowers in umbels; leaves oblong-egg-ſhaped, ſmooth, leathery." A ſhrub. *Branches* thick, ſtiff, ſmooth, pubeſcent towards their ſummit; ſpines two, crooked, placed near together. *Leaves* petioled, numerous and crowded. *Flowers* on ſhort peduncles, umbels terminating the branches. A native of the Cape of Good Hope, communicated to La Marck by Sonnerat. 14. C. *corymboſa*, Lam. 4. Willd. 11. (Cratæva, Adan. herb. Seneg. n. 41. A.) "Flowers in terminal corymbs; leaves oval, pubeſcent beneath." A ſhrub. *Branches* ſtiff, round, downy; ſpines two, crooked. *Leaves* petioled. *Flowers* peduncled; peduncles and calyxes pubeſcent. A native of Senegal.

** *Without ſpines.*

15. C. *cordiſolia*, Lam. 27. (C. mariana, Willd. 12.) "Peduncles ſolitary, one-flowered; leaves heart-ſhaped, petioled; younger ones covered with a mealy down." Lam. A ſhrub, reſembling in habit C. ſpinoſa. *Branches* cylindrical, full of pith. *Leaves* alternate, terminated by a blunt point, green on both ſides. *Flowers* axillary, white, large; peduncles ſhorter than the leaves; ſtamens a little longer than the petals. Found in the Marianne iſlands by Sonnerat. 16. C. *puticoſa*, Mart. 23. Mil. 7. "Peduncles ſolitary, one-flowered; leaves lanceolate, acute, perennial." *Stem* ſhrubby, from twelve to fourteen feet high, with a dark brown bark, and numerous ſtrong branches. *Leaves* of a thicker conſiſtence than thoſe of the Bay-tree, alternate, on ſhort petioles. *Flowers* axillary, ſmall, on ſhort peduncles; filaments white; anthers purpliſh. Sent to Mr. Miller from Tolu. 17. C. *arboreſcens*, Mart. 21. Mill. 3. "Peduncles ſolitary, one-flowered; leaves lanceolate-egg-ſhaped." *Stem* woody, from twelve to fourteen feet high, with a ruſſet bark and many branches. *Leaves* on long petioles. *Flowers* lateral, on long peduncles, ſimilar to thoſe of the next ſpecies. Sent to Mr. Miller from Carthagena in New Spain. 18. C. *Baducca*, Linn. Sp. Pl. 4. Willd. 12. Mart. 7. Lam. 13. (Badukka; Reed. Mal. 6. p. 105. tab. 57. Rai. hiſt. 1630. "Peduncles generally ſolitary, one-flowered; leaves perennial, oblong-egg-ſhaped, determinately crowded, naked." Linn. A ſhrub, five or ſix feet high. *Stem* the thickneſs of the human arm. *Leaves* alternate, acute, entire, ſmooth on both ſides, green, rather thick, ſoft, on ſhort petioles. *Flowers* axillary, and terminal, ſometimes two or three together, bluiſh white; petals unequal, wedge-ſhaped; ſtamens the length of the petals. 19. C. *ampliſſima*, Willd. 23. Lam. 14. (C. conſerta, Mart. 24. Mill. 8.? C. alia arboreſcens, lauri foliis, fructu oblongo ovato; Plum. Spec. 7. ic. 73. fig. 2.) "Peduncles one-flowered, ſolitary; leaves elliptical, ſmooth, veined; ſtamens longer than the corolla; fruit inverſely egg ſhaped." Confounded by Linnæus with the preceding. A conſiderable tree, with a thick, blackiſh wrinkled bark. *Leaves* towards the ſummit of the branches, numerous, alternate, of a beautiful green; reſembling thoſe of laurel, but larger, thicker, and leſs acute. *Flowers* axillary and terminal, large, white; petals concave, an inch and half long; ſtamens white, numerous, much longer than the petals; peduncles long. *Fruit* larger than a gooſe egg, fleſhy; rind thick, wrinkled. A native of Hiſpaniola. 20. C. *toruloſa*, Willd. 15. Mart. 19. Swartz. Prod. 81. (Breynia arboreſcens ſiliqua toroſa; Brown Jam. 246.) "Peduncles generally two flowered, terminal; leaves lanceolate-oval, dotted with white underneath, ſiliques round, linear, ſwelling into ſmall protuberances." A ſhrubby tree. Native of Jamaica. 21. C. *ſaligna*, Willd. 25. Vahl. Symb. 3. p. 66. "Peduncles two or three-flowered, ſolitary, terminal; leaves linear-lanceolate, dilated on each ſide towards the baſe, ſmooth; fruit round, ſwelling into ſmall protuberances." *Branches* round, zigzag, ſmooth, with an aſh-coloured bark. *Leaves* three inches long, a quarter of an inch broad towards the ſummit, generally broader towards the baſe, petioled, alternate, entire, mucronate, rounded, or a little heart-ſhaped towards the baſe, veined, ſmooth; petioles ſhort; frequently with ſmall axillary glands. *Calyx-leaves* rounded, leathery. *Filaments* numerous, very long, capillary, ſmooth. *Germ* linear-oblong, truncate. *Berry* two or three inches long, the thickneſs of a ſwan's quill, obtuſe, ſmooth, compreſſed between each ſeed; pedicel longer than the fruit. Seeds two or five. A native of St. Crux: Q. does it ſpecifically differ from the preceding? 22. C. *triflora*, Mart. 25. Mill. 10. "Peduncles three-flowered, terminal; leaves lanceolate, nerved, perennial." *Stems* ſhrubby, ſlender, ſeven or eight feet high, much branched. *Flowers* ſmall, white.

*Fruit* oval. Cultivated by Mr. Miller, but no native place mentioned. 23. C. *pulcherrima*, Linn. Sp. Pl. p. 1674. Willd. 26. Mart. 9. Lam. 25. Jacq Amer. 163. tab. 106. pict. 80. tab. 155. "Flowers in racemes; leaves oblong, obtuſe; berries roundiſh." An elegant, upright ſhrub; in open dry ſituations only two or three feet high, in woods twelve. *Branches* round, ſmooth. *Leaves* often ten inches long, alternate, petioled, entire, leathery,. ſhining. *Raceme* terminal, ſimple, upright, ſix inches long, handſome. *Flowers* pale yellow, ſweet ſcented; filaments at firſt white, then of a beautiful purple. *Berry* yellowiſh; pulp or fleſh when unripe, hard, with little ſcent; when ripe, ſoft, fetid and nauſeous. *Seeds* kidney-ſhaped, a little compreſſed, enveloped in a white, thin, ſtrong membrane. A native of Carthagena in New Spain, on the declivities of mountains. 24. C. *tenuiſiliqua*, Willd. 27. Lam. 23. Jacq. Amer. 162. tab. 105. "Racemes erect, terminal; leaves lanceolate-egg-ſhaped, acute; ſiliques cylindrical." A ſhrub, with few branches; in ſhady places fifteen feet high. *Leaves* alternate, petioled, ſhining, deciduous. *Racemes* ſimple, ſix or ſeven inches long, containing about fifty greeniſh white, ſcentleſs flowers, which open in ſucceſſion about the month of April, after the fall of the leaf. *Siliques* ſlender, ſix or ſeven inches long. A native of New Spain about Carthagena. 25. C. *linearis*, Linn. Sp. Pl. p. 1674. Willd. 28. Mart. 10. Lam. 20. Jacq. Amer. 161. tab. 102. "Peduncles ſomewhat racemed; leaves linear." A tree. *Stem* about fifteen feet high, upright, branched, elegant. *Leaves* four inches long, entire, leathery, blunt, with a very protuberant midrib; the ſides often revolute; petioles ſhort. *Flowers* about ten in a raceme, white, large, ſcentleſs. *Racemes* terminal or axillary. *Siliques* about an inch long, orange-coloured, ſwelling into protuberances. A native of New Spain about Carthagena. 26. C. *nemoroſa*, Lam. 26. Jacq. Amer. 164. tab. 181. "Flowers in racemes; leaves acuminate; fruit berry-ſhaped." A tree. *Stem* twenty feet high, uprigh, branched. *Leaves* leathery, ſhining above, covered beneath with a down, which rubs off when touched, and diſappears as the leaf grows old. *Fruit* oval-oblong. A native of woods near Carthagena. 27. C. *falcata*, Mart. 17. Loureiro Cochin. 331. "Flowers in racemes; leaves ternate, ſickle-ſhaped." A large tree with ſpreading branches. *Leaves* lanceolate-egg ſhaped; lateral ones ſickle-ſhaped at the baſe; entire, ſmooth, petioled. *Flowers* white; ſtamens eighteen. *Berry* oblong, red, large, one-celled, peduncled. *Seeds* many, bedded in the pulp. A native of China. 28. C. *racemoſa*, Mart. 22. Mil. dict. 5. "Flowers in racemes; leaves egg-ſhaped, oppoſite, perennial." A tree. *Trunk* about twenty feet high; branches numerous, long, ſlender; with a brown bark. *Leaves* like thoſe of the Bay-tree, but longer and deeply ribbed on their under ſide, on rather long petioles. *Flowers* large, white. *Siliques* two or three inches long, the thickneſs of a man's little finger, fleſhy. *Seeds* large, kidney-ſhaped. 29. C. *panduriformis*, Lam. 28. Willd. 13. "Peduncles one-flowered, aggregate, terminal; leaves oblong, fiddle-ſhaped." *Stem* ſhrubby. *Leaves* four inches long, an inch and half broad, alternate, acute, ſmooth, on ſhort petioles. A native of the Iſle of France, found by Sonnerat. 30. C. *haſtata*, Linn. Sp. Pl. 10. Willd. 30 Mart. 12. Lam. 21. Jacq. Amer. 159. tab. 174. fig. 56. "Peduncles many-flowered; leaves lanceolate-halberd-ſhaped, ſhining." An upright, weak ſhrub; branches few, often ſix feet long. *Leaves* alternate, petioled, from three to ſeven inches long, leathery. *Flowers* purple, ſweet-ſcented, in terminal racemes. 31. C. *Breynia*, Linn. Sp. Pl. 7. Willd. 29. Mart. 11. Lam. 16. Jacq. Amer. 161. tab. 103. (Breynia elæagni foliis; Plum. *gen.* 40. Breyn. ic. 13. c. *fig.*) "Peduncles in racemes; leaves permanent, oblong; peduncles and calyxes downy; flowers octandrous," Linn. "Peduncles many-flowered; leaves lanceolate-egg-ſhaped, ſhining above, rough with ſcaly points beneath; ſiliques round, ſwollen with the ſeeds, a little ſcaly." Lam. A ſhrub, or ſmall tree with the habit, according to Plumier, of an almond-tree or an Oleaſter. *Stem* upright, ſmooth; branches zigzag, brown, ſcarred with the fallen leaves, covered near the ſummit with ſmall ruſſet or ferruginous ſcales. *Leaves* little more than two inches long and one broad, alternate, ſmooth and ſhining above, hoary-ferruginous and roughiſh, with a mixture of ſilvery and ferruginous, very ſmall ſcales or dots beneath, ſimilar to thoſe of Hippophæ, ſome ſpecies of Ciſtus, and a few other plants; petioles angular, hoary-ferruginous. *Flowers* rather large, white, tinged with purple, very ſweet-ſcented, peduncles terminal, and axillary from the upper leaves, forming a ſort of corymb, from two to four-flowered; calyx-leaves reflexed, convex, white on the inſide, ferruginous beneath, and ſomewhat rugged; petals twice as large as the calyx, entire, ſpotted with ruſt colour on the outſide, deciduous; nectariferous glands four, ſmall, egg-ſhaped, acute, compreſſed, permanent; filaments long, meeting at the baſe round the germ, covered with a pale red pile, eight according to Plumier's figure; but Reichard aſſerts that they are more, and that the ſpecies is properly polyandrous; anthers almoſt erect, acuminate, curved inwards, yellow; germ elongated, minute, on a ſhort pedicel; ſtyle the length of the ſtamens; ſtigma thickened, obtuſe, ferruginous. *Fruit* from three to five inches long, cylindrical, two-valved. *Seeds* kidney-ſhaped. A native of the ſea-coaſt in the Weſt Indies. 32. C. *ſiliquoſa*, Linn. Sp. Pl. 6. Lam. 19. Mart. 14. (C. Breynia *β*. Willd.) "Peduncles one-flowered, compreſſed; leaves permanent, lanceolate-oblong, acuminate, dotted beneath." Linn. A native of Jamaica. *β*. leaves linear, narrow, very acute. A native of the Antilles. *Leaves* four or five inches long, ſmooth above, beſet with ſilvery and ferruginous ſcales beneath. Seen by La Marck in the herbarium of Juſſieu. 33. C. *ferruginea*, Linn. Sp. Pl. 8. Willd. 18. Mart. 6. Swartz. Obſ. 208. (C. octandra, Jacq. Amer. 160. tab. 100. bad. Cratæva foliis ſingularibus, Brown. Jam. 247. tab. 28. fig. 1. good. C. amygdalina, Lam. 17.?) "Peduncles in umbels; leaves permanent, lanceolate, downy beneath; flowers octandrous." Linn. A ſmall tree or ſhrub. *Branches* ſtriated, ferruginous. *Leaves* oppoſite, entire, ſmooth above, lanuginous-aſh-coloured beneath; petioles ferruginous, ſhort. *Flowers* white, terminal, on bifid and trifid peduncles, forming a corymb rather than an umbel, fragrant; calyx four-cleft, flat at the baſe, permanent; ſegments ſpreading, equal, acute; petals equal, concave; claws inſerted into the diviſions of the calyx, and of the ſame length; nectaries four, egg-ſhaped, placed between the petals and the column of the piſtil; filaments ſeldom more than eight, fixed to the pedicel of the germ, ſhorter than the corolla; anthers oblong, inſerted into the filaments; germ egg-ſhaped, on a round pedicel, half the length of the corolla; ſtigma ſeſſile, club-ſhaped. *Berry* fleſhy, oblong. *Seeds* five or ſix, oblong, Swartz. The plant is ſtrongly impregnated with an acrid, volatile ſalt, like the muſtard tribe; and hence, in Jamaica, where it grows wild, it is called the muſtard plant. Browne miſled by this circumſtance, and the regularity of the calyx, petals, and nectaries, referred it to the claſs tetradynamia. Martyn's Miller. La Marck gives the following ſpecific character and deſcription of his C. amygdalina, which he conjectures may be the ferruginea of Linnæus. "Peduncles many-flowered; leaves oblong-lanceolate; veined, ſmooth above; ſcaly-ſilvery beneath." Young branches, petioles, peduncles, and calyxes covered, like hippophæ rhamnoides, with ferruginous ſcales. *Leaves* alternate, petioled, acute, ſmooth above, but not ſhining like thoſe of C. breynia; covered beneath with ſmall, ſilvery, roundiſh ſcales, having a ferruginous dot in the middle; from three to four inches long, and ſcarcely an inch broad. *Flowers* rather ſmall, terminal, ſeveral together, on ſhort peduncles. *Siliques* five or ſix inches long, cylindrical, a little ſwollen by the ſeeds, and of a reddiſh colour. A native of the Antilles, and deſcribed from a dried ſpecimen in the herbarium of Juſſieu. 34. C. *odoratiſſima*, Willd. 21. Jacqr. hort. Schreb. 1. p. 57. tab. 110. "Peduncles many-flowered; leaves oblong-lanceolate, dotted with ſcales beneath." *Leaves* attenuated and rounded at the baſe, acute at the ſummit. *Flowers* the ſize of thoſe of the common myrtle. *Petals* violet. *Stamens* a little longer than the corolla. The ſpecific character as given by Willdenow is not ſufficiently diſcriminative. 35. C. *longifolia*, Willd. 16. Mart. 20. Swartz Prod. 81. Pluk. phyt. tab. 327. fig. 6. "Infloreſcence unknown; leaves linear-lanceolate, with mealy dots underneath." A native of Jamaica. 36. C. *jamaicenſis*, Willd. 20. Lam. 22. Jacq. Amer. 160. tab. 101. "Peduncles many-flowered; leaves oblong, obtuſe, emarginate, downy beneath; corolla ſemi-erect, or bell-ſhaped." A ſhrub about ſix feet high, upright, branched, buſhy; old branches ſmooth, blackiſh; young ones downy, aſh-coloured. *Leaves* alternate, petioled, leathery, two inches long. *Flowers* yellowiſh white, fragrant; peduncles downy, terminal, and axillary. A native of Jamaica. 37. C. *cynophallophora*, Linn. Sp. Pl. 5. and C. flexuoſa. Sp. Pl. 9. Willd. 24. Mart. 8. Lam. 15. Jacq. Amer. 158. tab. 98. C. arboreſcens, fructu longiſſimo. Plum. Sp. 7. ic. 73. fig. 1. (Cynophallophorus, Pluk. 126. tab. 172. fig. 4. moriſonia flexuoſa, Amæn. Acad. 5. p. 398. Breynia foliis oblongis obtuſis, Browne Jam 246. tab. 27. fig. 1. Acaciæ affinis, ſiliqua tereti ventricoſa interiore tunica mucoſa miniata, Sloane Jam. 1538. hiſt. 2. p. 59.) "Peduncles many-flowered, terminal; leaves elliptical, obtuſe, ſmooth; glands axillar; fruit cylindrical, ſwollen by the ſeeds." Willd. A ſhrub twelve feet high in a good ſoil. *Branches* long, weak, pendant, or ſupported by the neighbouring ſhrubs. *Leaves* about three inches long, alternate, ſmooth, veined, on ſhort peduncles. *Flowers* white, large, very fragrant; ſtamens often four inches long. *Siliques* about ſix inches long, as thick as the human finger, opening longitudinally by two valves. *Seeds* kidney-ſhaped, very white, bedded in the bright ſcarlet fleſh, or pulp of the valves. A native of the Weſt Indies, ſent to Mr. Miller from Carthagena. Willdenow makes the flexuoſa of Linnæus a variety, but according to Martyn, it has been determined from an imperfect ſpecimen in the Linnæan herbarium, to be in no wiſe different from C. cynophallophora. 38. C. *verrucoſa*, Willd. 22. Lam. 24. Jacq. Amer. 159. tab. 29. "Peduncles many-flowered; leaves oblong, acute, gloſſy on both ſides; fruit warty." Habit of the preceding. *Axillary* glands none. *Flowers* white, very open, with little ſmell; nectariferous glands flat, umbilicated; ſtamens an inch long, not much longer than the corolla. *Silique* oblong, round, green, ſhining, entirely covered with warts, two-valved, about an inch and half long; pulp white. Jacq. A native of thickets about Carthagena. 39. C. *frondoſa*, Linn. Sp. Plant. p. 1674. Willd. 17. Mart. 5. Lam. 12. Jacq. Amer. 162. tab. 104. "Peduncles in umbels; leaves crowded on all ſides." A ſhrub commonly about ſeven feet high, but in thick ſhady woods not leſs than twenty; branches few. *Leaves* varying in ſize, the largeſt near a foot long, broad-lanceolate, acuminate, ſmooth, nerved, veined. *Flowers* an inch in diameter, greeniſh, or purple, ſcentleſs; common peduncle round, ſhining, erect, terminal. *Fruit* cylindrical, an inch and half long, ſhining, dark purple; fleſh whitiſh. A native of South America. 40. C. *grandis*, Linn. jun. Supp. 263. Willd. 19. Mart. 15. Lam. 11. "Corymbs terminal; leaves egg-ſhaped, acute, ſmooth; fruit globular." A large hoary tree. *Leaves* alternate, entire, veined. *Flowers* pale yellow, in terminal corymbs, which are finally elongated into racemes. *Fruit* large. A native of the iſland of Ceylon. 41. C. *magna*, Mart. 16. Loureiro Cochin. 331. "Corymbs terminal; leaves ternate, lanceolate." A middling ſized tree. *Branches* ſpreading. *Leaves* entire, ſmooth. *Flowers* large, white; calyx wheel-ſhaped; ſegments lanceolate, flat, interrupted; petals broad-egg-ſhaped, ſharp at both ends, many-nerved, veined, ſpreading, equal, with long claws; filaments twenty-four, very long; anthers three-celled, oblong, recurved; germ roundiſh, pedicelled; ſtyle ſhort. *Berry* two inches long, roundiſh, fleſhy, eatable, dotted, rough, one-celled. *Seeds* numerous, kidney-ſhaped, bedded in the fleſh, or pulp. A native of Cochinchina, much reſembling C. grandis, and differing from it chiefly in its ternate leaves. 42. C. *oblongifolia*, Lam. 29. Forſk. Ægyp. p. 99. "Leaves oval-oblong, obtuſe, but ending in a ſharp pointed tooth, perennial." 43. C. *mithridatica*, Lam. 30. Forſk. Ægyp. 99. "Leaves alternate, pendulous, linear-lanceolate."

Obſ. The fruit of this remarkable genus merits a more accurate inveſtigation. Authors are not agreed what it ſhould be called in ſeveral of the ſpecies, and ſeem to have given it a name rather from its external form, than from a proper regard to its internal ſtructure.

*Propagation and Culture.*—Theſe plants can be raiſed in England only from ſeeds, which ſhould be brought over in the capſules wrapt up in well-dried tobacco leaves to preſerve them from inſects. As they germinate immediately when freſh, it is not eaſy to get them dry to Europe; on that account they are ſcarce in our ſtoves, although many of them were cultivated by Miller. The ſeeds ſhould be ſown in ſmall pots, filled with light ſandy earth, and plunged into a hot-bed of tanners-bark; and ſhould be allowed only a ſmall quantity of water. They will frequently remain in the ground a whole year before they vegetate, and therefore require protection in winter. In the ſpring following, the pots muſt be plunged into a freſh hot-bed, and when the plants are come up, ſhould have much air and little water. When large enough to remove, they ſhould be tranſplanted ſingly into ſeparate pots. In autumn they muſt be taken into the ſtove, and plunged into the hot-bed, where they ſhould conſtantly remain, and be treated like other plants from the ſame countries, but ſhould never have much water. Miller.

CAPPARIS *Moriſonia*, (Swartz.) See MORISONIA.

CAPPARIS *Fabago*, (Dodoens.) portulacæ folio, (Bauh. pin.) See ZYGOPHYLLUM *Fabago*.

CAPPEL, LEWIS, in *Biography*, an eminent French Proteſtant divine and Scripture critic, was born at Sedan in 1585; and becoming miniſter and Hebrew profeſſor at Saumur, he diſtinguiſhed himſelf in the controverſy concerning the antiquity of the Hebrew vowel-points. His elaborate work, entitled "Arcanum punctuationis revelatum," Leyd. 1624, contains ſtrong arguments to prove that the points were not uſed by the original Hebrew writers, but were added to the text by the Maſorites. He alſo maintains, that the characters of the Hebrew text were thoſe uſed by the Chaldæans after the Babyloniſh captivity, and that before that period the Jews always employed the Samaritan character. The members of the reformed and Lutheran churches were alarmed by this hypotheſis, conceiving that it tended to diminiſh the authority of Scripture, and to reduce it to a level with tradition. The Roman Catholics, on the other hand, eagerly adopted it. It is affirmed, however, that the leaders of the reformation, Luther, Zuingle, and Calvin, were of the ſame opinion, and the hypotheſis is now very generally received. Cappel, unintimidated by oppoſition, purſued his plan, and in his famous work, entitled, "Critica Sacra," fol. Paris, 1650, produced a number of various readings, and a liſt of the errors of copyiſts in the Bible, accompanied with critical remarks. See Bible. The printing of this work was delayed for 10 years, by the oppoſition it met with at Geneva, Sedan, and Saumur; till at length a ſon of Cappel, who was a convert to popery, obtained permiſſion by the intereſt of fathers Petau, Morin, and Merſenne, to print it at Paris. It was warmly attacked by John Buxtorf, in his "Anticritica," and by other divines; but Grotius, in a letter to the author, expreſſed his approbation of the work. Cappel likewiſe publiſhed "Sacred Chronology," Paris, 1655, which is printed by Walton in the Prolegomena to his Polyglott. After his death were printed his "Commentaries, theological and critical, on the Old Teſtament," together with the defence of his "Arcanum," at Amſterdam, 1689, fol. This learned writer died at Saumur in 1658. Moreri. Moſheim, E. H. vol. v. p. 377, &c.

Cappel, in *Geography*, a place of Swiſſerland, in the canton of Zurich, where, on account of a religious diſpute, a battle was fought between the Catholics and Proteſtants, in 1531, in which Zuingle, the reformer, loſt his life; 9 miles S. of Zurich.

Cappel, or Waldkapel, a town of Germany, in the circle of the Upper Rhine, and principality of the Upper Heſſe; 22 miles S.E. of Caſſel.

Cappel, or Kappel, a ſmall but neat town of Denmark, in the duchy of Sleſwic, on the eaſt coaſt; 16 miles N.E. of Sleſwic. It contains about 550 inhabitants, who are induſtrious, and carry on ſome trade, exporting bacon, cheeſe, butter, eggs, and other commodities to Copenhagen, and ſupplying the interior parts of the province with coffee, ſugar, ſpices, and other foreign merchandiſe. The environs of Cappel are very pleaſant, being grounds gently riſing, ſprinkled with much wood, and commanding fine views of the bay. N. lat. 54° 44′. E. long. 10°.

CAPPELLA, *Ital.* a *chapel.* This ſubſtantive is rendered a muſical term on many occaſions, as *maeſtro di cappella,* a chapel maſter, or the director and compoſer of a chapel eſtabliſhment, a coryphæus. *A cappella,* muſic in a chapel or church ſtyle. But the title of *maeſtro di cappella* is not confined to eccleſiaſtical compoſers and maſters of a choir, but is extended to compoſers of an opera, and to compoſers in general. Nor does *cappella* always imply that a prince or nobleman who retains a band of vocal and inſtrumental performers in his ſervice, has choral duty daily performed in his chapel; but that he has a band for his evening or occaſional concerts, in his palace or manſion; as was the caſe with the duke of Chandos, at Cannons, in the beginning of the laſt century.

CAPPELLINE, in *Heraldry,* a mantling, or a ſort of covering or hood, repreſented entire; not cut, and hanging back over the neck of the wearer. See Mantling.

CAPPELLO, Bernardo, in *Biography,* a celebrated Italian poet, was born at Venice about the beginning of the 16th century, and imbibed from Bembo, with whom he was intimate, the principles of Italian poetry. To his judgment, however, Bembo ſubmitted his own poems. Cappello, in conſequence of an opinion maintained by him in the ſenate, which was thought to be dangerous to the public tranquillity, was baniſhed in 1540, to the iſle of Arbe in Sclavonia, where he continued two years; but being cited to give an account of his conduct, he thought it moſt prudent to ſeek refuge, with his wife and family, in the eccleſiaſtical ſtate, where he was honourably received by cardinal Alexander Farneſe, and appointed governor of Orvieto and Tivoli. After ſpending ſome time at the court of Urbino, the reſort of the fineſt geniuſes of Italy, he was induced, on account of the inſalubrious air of Piſaro, to return to Rome in 1559, where he died in 1565. The "Canzonier" of Cappello is much celebrated, as an excellent model for ſtudents in poetry. A new edition of his poems, together with thoſe of Domenico Vaniero, was publiſhed in Bergamo in 1751 and 1753. Tiraboſchi. Gen. Biog.

CAPPELN, in *Geography,* a town of Germany, in the circle of Weſtphalia, and county of Tecklenburg; 8 miles N.N.E. of Tecklenburg.

CAPPENBERG, a town of Germany, in the circle of Weſtphalia, and biſhopric of Munſter; 6 miles N.W. of Werne.

CAPPENDU, a town of France, in the department of the Aude, and chief place of a canton in the diſtrict of Carcaſſonne; the place contains 586, and the canton 4644 inhabitants: the territory comprehends 167½ kiliometres and 11 communes.

CAPPEROL Coronde, a name given by the Ceyloneſe to a peculiar kind of cinnamon, eſteemed the third in value: this has a very ſtrong taſte and ſmell of camphor, and its name with the natives ſignifies camphorated cinnamon. The tree which produces it, grows very plentifully in many parts of the iſland of Borneo, but it is not met with in the eaſtern parts of it. This is often ſold to the Danes and Engliſh who come to trade on the coaſts of Coromandel; it is prohibited exportation from the iſland, but ſo long as only one port is open, there are people enough who will carry out great quantities of it.

There is a ſpecies of canella very much reſembling this kind of cinnamon-tree, which grows very frequently on the continent of India toward Goa; and another canella or wild cinnamon on the coaſt of Malabar, in many reſpects reſembles this. The barks of all theſe trees are greatly inferior to the true cinnamon in ſmell, taſte, and virtue; yet they are too often ſold to the leſs judicious traders in theſe things, either alone or mixed with the ſeveral better kinds of cinnamon, to the great damage of all that afterwards buy them. Phil. Tranſ. N° 409.

CAPPERONNIER, Claude, in *Biography,* a learned philologiſt, was born at Montdidier, in Picardy, in 1671. After having acquired, by his own ſtudy, the rudiments of the Latin tongue, he proſecuted his ſtudies for 18 months at the college of Montdidier, then at the Jeſuits' college of Amiens, and laſt of all in a ſeminary at Paris. Having taken orders, and ſupported himſelf by the profits of a ſmall benefice, and by teaching the claſſics, he obtained the patronage of M. Coleſſon, who had been his pupil, and in 1706 was admitted into his houſe, where he continued ten years, applying with great aſſiduity to the ſtudy of the Greek authors. Declining the offer of a Greek profeſſorſhip in the univerſity of Baſil, he determined, in 1710, to undertake the education of the children of M. Crozat, and continued in his family to the cloſe of his life. In 1722, he was nominated profeſſor of Greek in the royal college of Paris, and on his introduction to this office he delivered a Latin oration on the uſe and excellence of the Greek language, which was much applauded. In 1725 he publiſhed an excellent edition of "Quintilian" in folio, for which he received a penſion from the king, to whom it was dedicated. Burman rudely criticiſed it; but the editor defended it with politeneſs and modeſty. In 1719 he printed "An Apology for Sophocles," as a reply to the criticiſms of Voltaire on the Oedipus of this tragedian. He died in 1744, leaving a character of amiable ſimplicity, great piety and probity, and ſingular benevolence and kindneſs. He was diſtinguiſhed by a very retentive memory. Among various works which he left for the preſs were an edition of the "Antiqui Rhetores Latini," with notes and illuſtrations, publiſhed at Straſburg in 1756, 4to.; and "Philological Obſervations" on Greek and Latin authors, which would amount to ſeveral volumes in 4to. He alſo completed a "Treatiſe on the ancient Pronunciation of the Greek language," and made great additions and corrections to Stephens's Latin Theſaurus.

Capperonnier, John, the relation of the former, and his ſucceſſor in the Greek profeſſorſhip, publiſhed an edition of "Cæſar's Commentaries," 2 vols. 12mo. 1755, and of the "Comedies of Plautus," 3 vols. 12mo. 1759. He died at the age of 59, in 1775. Nouv. Dict. Hiſt.

CAPPERS, a denomination given in our ſtatutes (13 Eliz. c. 19. A. D. 1571) to the knit-cap makers, who manufactured caps of wool, and who obtained encouragement in oppoſition to thoſe who made hats of felt, and who imported foreign materials for this purpoſe. But knit-caps have been long ſince diſuſed.

CAPPONI, or Capponio, John Baptist, in *Biography*, a phyſician, poet, and aſtrologer, was born at Bologna in Italy, in the early part of the 17th century. He taught philoſophy and medicine at Bologna, where he publiſhed, under the name of Chariſius Thermarius Spado, "Animadverſiones in Joannis Caroli Sorcii Opuſculum de Febribus." After his death, which happened Nov. 16th, 1676, the following were printed: "Lectiones Phyſicæ Morales;" "De Morbis particularibus;" "De Humano Semine nequaquam animato;" "De Erroribus Clarorum Virorum Latinorum;" "Parodoxon Philoſophiæ Democraticæ." He is ſaid to have meditated, and in part executed, a general hiſtory of medicine, but it was never publiſhed. Eloy. Dict. Hiſt.

CAPPOQUIN, in *Geography*, a ſmall town of the county of Waterford, province of Munſter, Ireland, ſituated on the river Blackwater, which here takes a ſouthern direction, and becomes navigable. There is a wooden bridge here over the Blackwater, which was rebuilt at the expence of the ſouthern counties in the reign of Charles II. and which is now almoſt impaſſable. The ruins of the caſtle are near the bridge, and the whole town appears neglected and going to decay, notwithſtanding its advantages for trade, and the richneſs of the adjoining country. The road from this to Liſmore is remarkably beautiful; and the proſpects from the high grounds above the town can ſcarcely be ſurpaſſed. It is 98 Iriſh miles S.W. from Dublin, and 5 miles eaſt of Liſmore. N. lat. 52° 9′. W. long. 7° 53′. Smith's Waterford, &c.

CAPRA, in *Aſtronomy*, a denomination given to the ſtar Capella; and ſometimes alſo to the conſtellation Capricorn. Some repreſent *Capra*, or the *ſhe-goat*, as a conſtellation in the northern hemiſphere, conſiſting of three ſtars, compriſed between the 45th and 55th degree of latitude. The poets ſay, it is Amalthea's goat, which ſuckled Jupiter in his infancy. Horace, making mention of it, calls it, *Inſana ſidera Capræ*.

Capra, Marcellus, in *Biography*, a native of the iſland of Cyprus, where he appears to have practiſed medicine during the early part of his life. Induced at length to quit his native country, he went to Meſſina, where he ſoon became ſo diſtinguiſhed as to be appointed by the magiſtrates phyſician to the city. This happened about the year 1570. He was author of ſeveral abſtruſe, metaphyſical works, ſuiting the humour of the time; but what alone ſeems deſerving notice, is his account of a fatal epidemic prevailing in the iſland of Sicily, during the years 1591 and 2. "De Morbi Epidemici qui miſerrime Siciliam depopulabat Anno 1591 itidemque 1592, Cauſis, Symptomatibus, et Curatione," Meſſanæ, 1593, 4to. Haller Bib. Med. Eloy. Dict. Hiſt.

Capra, in *Geography*, a ſmall Greek iſland, N.W. of the iſle of Stancho, inhabited only by goats, as its name imports.

Capra, in *Zoology*, a genus of the *Mammalia* claſs in the order *Pecora*.

The quadrupeds of this tribe have the horns hollow, turning upwards, and bent back, compreſſed, and rough: front teeth in the lower jaw eight: canine teeth none: chin bearded.

Theſe are the goats of Engliſh writers, including our common goat, and its numerous varieties. The ſpecies of this genus already aſcertained are few, amounting only to two, or three at the utmoſt, if the domeſticated goat, *Capra hircus*, be conſidered as the genuine offspring of either of thoſe ſpecies known in a ſtate of nature at this time. It is thought by many, and the opinion is highly probable, that our common goat originated from the *Caucaſan ibex*, *Capra ægagrus*, or perhaps from the Ibex goat, *Capra Ibex* of Linnæus. We can ſay but little as to the third ſpecies that might have been the parent ſtock of our preſent race of domeſtic goats, the *Capra caucaſica* of Güldenſtedt deſcribed in the Tranſactions of the Ruſſian Academy for the year 1779; becauſe it appears rather doubtful whether we ought to admit it as a ſpecies altogether diſtinct from capra ægagrus, or not.

In the twelfth edition of the Syſtema Naturæ, the capra genus will be found far more extenſive; Linnæus having claſſed ſeveral animals of the antelope tribe as ſpecies of this genus. The Swediſh naturaliſt was unqueſtionably juſtified in this reſpect, both by his own opinion, and by the example of ancient writers with ſcarcely an exception from the time of Pliny. They had, for inſtance, uniformly conſidered the chamois as appertaining to the race of goats; it was their *rupicapra*, and even to this day it paſſes under the trivial name of the chamois goat, though in the ſyſtematic writings of modern zoologiſts it claſſes in the genus antelope. That the natural generical diſtinctions, if they may be ſo expreſſed, obſervable between the goat and the antelope tribes did not ſtrike the mind of Linnæus may be preſumed as evident; there was but an inconſiderable number (about ſix ſpecies) of the antelope known in his time, and thoſe he placed without heſitation with the goats in his genus capra.

The obſervations of later naturaliſts prove ſufficiently that Linnæus might have ſeparated the goats from the antelopes with much propriety: were we to diſtruſt the truth of this aſſertion, the writings of Pallas, of Schreber, Erxleben, Güldenſtedt, Pennant, and Sonnini muſt ſilence every doubt. Gmelin, the editor of the laſt edition of the Syſtema Naturæ, has availed himſelf of theſe recent authorities, the antelopes are ſeparated from the goats under the generic name of antilope, the goats retaining the original appellation of capra.

A principal diſtinction between the two genera conſiſts in the ſtructure of the horns, thoſe of the antelope being round and nearly cylindrical, and either twiſted ſpirally, or annulated: the teeth are exactly the ſame in both; but the chin of the goat is bearded, while that of the antelope is not. A further very ſtriking difference between the goat and the antelope is obſervable in the general figure of theſe animals. The goat is robuſt, ſtrong, vigorous, petulant, and fearleſs; the antelope is of a graceful form: its limbs long and ſlender: its diſpoſition timid, harmleſs, active, and watchful; and in the chace, when purſued on the open plains, its courſe incomparably more ſwift than that of the goat.

Beſides, therefore, the peculiar ſtructure of the horns, and other characteriſtic particulars laid down by ſyſtematic writers, the manners and habits of life ſufficiently prove that a line of ſeparation ought to be drawn between the antelope and the goat. Mr. Pennant in his preface to the Synopſis of Quadrupeds treats on this ſubject at ſome length: his remarks are uſeful, and although they relate more immediately to the antelope than the goat, the leading points of his argument may be properly noticed in this place.—"The antelopes (ſays this author), two or three ſpecies excepted, inhabit the hotteſt parts of the globe; or at leaſt, thoſe parts of the temperate zone that lie ſo near the tropics as to form a doubtful climate. None, therefore, except the Saiga, and the chamois, are to be met with in Europe; and notwithſtanding the warmth of South America is ſuited to their nature, not a ſingle ſpecies has yet been diſcovered in any part of the new world. Their proper climates ſeem, therefore, to be thoſe of Aſia and Africa, where the ſpecies are very numerous."—"As there appears a general agreement in the nature of the ſpecies that form this great genus, it will prevent needleſs repetition to obſerve, that the antelopes are animals generally of a moſt elegant and active make; of a reſtleſs and timid diſpoſition; extremely watchful; of great vivacity; remarkably ſwift and agile, and moſt of their boundings ſo light, ſo elaſtic, as to ſtrike the ſpectator with aſtoniſhment."—"Antelopes generally reſide in hilly countries, though ſome inhabit plains; they often brouſe like the goat, and feed on the tender ſhoots of trees, which gives their fleſh an excellent flavour. This is to be underſtood of thoſe which are taken in the chace; for thoſe which are fattened in houſes are far leſs delicious. The fleſh of ſome ſpecies is ſaid to taſte of muſk, which perhaps depends on the qualities of the plants they feed upon."—"This preface (ſays Pennant) was thought neceſſary, to point out the difference in nature between this and the goat kind, with which moſt ſyſtematic writers have claſſed the antelopes: but the antelope forms an intermediate genus, a link between the goat, and the deer; agreeing with the former in the texture of the horns which have a core in them and are never caſt; and with the latter in elegance and ſwiftneſs."

From the tenor of the preceding obſervations it will be perceived that the lateſt and beſt informed zoologiſts conſider it as a decided point that the antelopes and the goats ought to be ſeparated, and we ſhall therefore ſpeak of the ſpecies of Capra as they ſtand independent of the genus antilope.

Capra *Ibex.* Horns on the upper ſurface knotty, and bending over the back: throat bearded. Briſſ. reg. an.—Linn.

*Ibex* of Pliny, Geſner, Aldrovandus.—*Ibex alpium ſibiricarum*, Pallas.—*Capra alpina*, &c. Girtanner.—*Stein-bock*, Geſner.—*Bouquetin*, Buffon, Sonnini, &c.—*Ibex goat*, Pennant.

Steinbock is the familiar title, by which this animal is better known than any other. The name is derived from the German *ſtein* and *bock*, or buck of the rock, conveying at once an idea of the animal, and the ſituations in which it delights, and is commonly found. The French name bouquetin is of German origin, and in England the ſpecies is better known by the name of ſteinbock, than that of ibex goat, as it is called by Pennant. In its general appearance it reſembles the common goat, but it is conſiderably larger, more vigorous, and more active. The colour is a deep hoary or greyiſh brown; much paler, or whitiſh beneath, and on the inſides of the limbs; the outſides of which are duſky, or blackiſh on the lower part: the back is marked with a diſtinct black line. The body is robuſt; the head ſhort, ſmall and compreſſed; the eyes are ſmall, but full of fire and expreſſion. The horns in the male are extremely large, meaſuring from two to three feet in length, and weighing eight or ten pounds; they are of a livid blackiſh colour, and are marked on the upper ſurface with tranſverſe protuberant ſemicircles, which it is reported indicate by their number the age of the animal, one additional being formed every year. Theſe horns are thick at the baſe; and ſometimes become ſo prodigiouſly large as to extend the whole length of the body. The female is ſmaller than the male: her horns are ſmaller in proportion, leſs diſtinctly marked with ſemicircular protuberances, and much weaker than thoſe of the male. The legs are ſhort, but the males are very ſtout, and the hoofs ſhort. The tail is ſmall and of a blackiſh colour. The young ſteinbocks are of an aſh-coloured grey.

The ibex is found in ſeveral parts of Europe and Aſia, and it is ſaid on all the great chains of mountains in the northern parts of the ancient hemiſphere, upon the Alps, the Pyrenées, the Apennines, and Tyrol. In Aſia it occurs on the ſummits of the chain of mountains extended from Taurus, and continued between Eaſtern Tartary and Siberia. It alſo inhabits the tract beyond the Lena, and is ſaid by Virey to be a native of the mountains of Kamtſchatka. In Arabia it is not uncommon, and in the high mountains of the iſland of Crete it appears to be abundant.

In its general habits or manners this animal reſembles the common goat, but poſſeſſes every attribute of ſtrength and activity in a degree proportioned to its natural ſtate of wildneſs. It inhabits the moſt inacceſſible places among rocks and precipices in the higheſt regions of the mountains, where it finds all that is neceſſary for its frugal ſubſiſtence in the midſt of ſolitude and ſecurity. Sonnini obſerved them on many of the loftier elevations of the mountains in the iſle of Candia, and ſeveral other iſlands in the ſame ſea, and beyond the upper half of Mount Olympus he found there were hardly any quadrupeds to be ſeen, except a few bears, and the bouquetins, or mountain-goat, capra ibex, who appeared to be ſole maſters of this ſolitary waſte of nature.

The chace of the ſteinbock, like that of the chamois, is both difficult and perilous. When it retreats among the crags and precipices it is impoſſible to purſue the animal in ſafety; the chace is then left to the dogs who are taught to hunt them over the moſt tremendous paſſes of the mountains amidſt ice and ſnow, where many of the dogs are ſometimes loſt in the vain attempt to follow or overcome their game. But ſhould the mountain huntſman once get ſight of the ſteinbock at a diſtance from his dogs and within the range of his rifle piece he inſtantly takes an aim, and ſeldom fails to wound or kill the animal at the firſt fire. It is in this manner they hunt both the ſteinbock and the chamois on the Tyroleſe mountains. The fleſh of the young ibex is ſaid to be in eſteem as an article of food: that of the old ones is alſo eaten, and its fleece and ſkin employed for various purpoſes. We may farther add that this is the animal whoſe blood was formerly conſidered as a valuable article in the materia medica, being celebrated for its ſuppoſed power of relieving pleuritic and many other complaints. Of its wonderful virtues in this way much has been related in the works of Geſner and Aldrovandus. Its period of geſtation is five months as in the common goat.

Capra *Ægagrus.* Horns carinated, and arched back; throat bearded. Pallas. S. G. Gmelin.

*Chevre ſauvage,* Tavernier. *Caucaſan ibex,* Pennant. *Steinbock,* Ridinger.

The caucaſan ibex is conſiderably ſuperior in ſize to the common goat, and its form, in ſome degree, reſembles that of the ſtag. According to Pallas, who deſcribes this animal with accuracy, the general colour of it is greyiſh, intermixed with ruſty, or ferruginous above, and white beneath. The forehead nearly black, which colour is continued in a narrow ſtripe along the middle of the back to the tail. The chin is furniſhed with a large beard of a duſky colour mixed with cheſnut. The horns, which are very large and bend conſiderably backwards, are ſmooth, black, ſharply ridged on their upper part, and hollowed on the exterior ſide; they have no appearance of either knots or rings, but are marked on the upper ſurface by ſome obſcure undulations or ſlight wavy wrinkles: they are about three feet in length, and ſtand cloſe at the baſe, about a foot diſtant at the wideſt part; and eight or nine inches at the tips. The female has either very ſhort horns, or is entirely deſtitute of them, and has no beard.

In point of ſtrength and agility this ſpecies is at leaſt equal, if not ſuperior to the common ſteinbock. Monardes compares it to the he-goat. It inhabits the lower mountains of Caucaſus and Taurus, almoſt all Aſia Minor, and may probably extend even to India. It abounds on the inhoſpitable hills of Laar and Choraſan in Perſia, and according to Monardes, it is likewiſe found in Africa. Mr. Pennant is inclined to believe that it may exiſt in Crete, and even on the Alps, grounding his idea on a figure in one of the works of Ridinger, which ſeems intended for the ſame animal. Monardes aſſures us he was an eye witneſs to the manner in which this animal ſaves itſelf from injury by falling upon its horns from a conſiderable height; for he ſaw the animal he deſcribes leap from a high tower, and precipitating itſelf on its horns, ſpring up again, and leap about without having to all appearance received the ſlighteſt injury. In the ſtomach of this animal, as in ſome of the antelopes, and other quadrupeds, is found the animal concretion, called bezoar, the once highly valued alexipharmic, the pretended medicinal virtues of which have been long ſince exploded.

Capra *Caucaſica.* Horns turned backwards, and outwards, verging inwards at the tips, ſlightly triangular, and knotty before. Gmelin. Güldenſtedt, &c.

This animal, which Pennant includes in his deſcription of the caucaſan ibex (capra ægagrus) as a variety, ought, according to Güldenſtadt, to be conſidered as a diſtinct ſpecies. In ſize it nearly correſponds with the domeſtic goat, but is broader and ſhorter, and the horns of the male are much larger in proportion, being ſometimes more than two feet in length. The horns of the male are darker than in the female. The colour of the animal is a ferruginous or browniſh grey above, with a ſubfuſcous ſpiral line: beneath white: extremities black. The hair is cinereous at the baſe, rigid, and intermixed with wool.

Capra caucaſica inhabits the bare ſchiſtous ſummits and cliffs of Mount Caucaſus near the origin of the Terek and Cuban rivers. They couple in November, the female brings forth her young in April.

Capra *Hircus,* the common, or domeſtic goat. Horns carinated, arched, with a curvature outwards at the extremities.

*Capra Hircus,* β Linn.—*Capra, hircus, hoedus.* Pliny, Aldrovandus, &c. *Caper hiſpanicus,* Jonſt. Τραγοι and Αιγες. Ariſt. &c.—*Bouc et chevre,* Buffon, &c.—*Becco, capra,* Ital. —*Bock et Geyſs,* Germ.—*Domeſtic goat,* Engl.

"The origin of the domeſtic goat (ſays Mr. Pennant in his Britiſh Zoology) is the ſteinboc, ibex, or wild goat, a ſpecies now found only in the Alps, and in Crete." The facts already related in the hiſtory of capra ibex clearly prove the writer to be miſtaken in aſſerting it to be found only in the Alps and in Crete; the obſervation is merely introduced to ſhew that he believes the ibex to be the parent ſtock from which the domeſtic goat originated.

To aſcertain the point in a ſatisfactory manner is perhaps impoſſible: we muſt allow our opinions to fluctuate, between probabilities and poſſibilities without conceiving in our own minds the chance of arriving, with any abſolute ſhare of certainty, at the real truth. Pallas allows that capra ibex may have been the original from which the domeſtic goat is derived, at the ſame time that he is inclined to think with equal probability it may have derived its origin from capra ægagrus, the caucaſan ibex of Pennant. The latter notion ſeems moſt prevalent; Gmelin adops it; and we are led to think on a point ſo ambiguous, not entirely without reaſon.

Buffon conſiders the capra ibex, the chamois antelope, and the domeſtic goat, as one and the ſame ſpecies. He ſpeaks of it as likely that the male ibex coupling with the female chamois may have given riſe to the preſent domeſtic race of goats.—"There are many caſes (ſays this lively writer in another place) in which we cannot diſtinguiſh characters, nor pronounce on differences with certainty: there are others in which we are obliged to ſuſpend our judgment and opinions; and in a great number of others we have not the ſlighteſt ray of light to direct us; for independent of the uncertainty ariſing from the contrariety of aſſertions relative to recorded facts: independent of the doubts reſulting from the inaccuracy of thoſe who have endeavoured to obſerve nature, the greateſt obſtacle to the advancement of knowledge is our ignorance of a great number of effects which time has not diſcloſed to us."—"We are ignorant whether the chamois goat be any thing more than the common goat in a wild ſtate, or whether an intermixture would not form an intermediate race."—The naturaliſts of France, though proud of their immortal Buffon, cannot accede to this inconſiſtent flight of his imagination. Sonnini, the editor of the laſt edition of his works, ſpeaks of it as erroneous. Another French writer is more explicit: "It is abſurd (he thinks) to ſuppoſe with Buffon that our race of domeſtic goats were produced from an intermediate breed between the bouquetin (capra ibex) and the chamois; an inſpection of the exterior characters, and the internal organization of the three animals, to ſay nothing of their manners of life, ſeems to deſtroy all ideas of their being ſpecifically the ſame." That the preſent race of goats cannot be the lineal offspring of the croſs breed between the ibex and the chamois, as Buffon thought, ſeems unqueſtionable; yet we think it pretty certain, from the evidence above adduced, that they may be the deſcendants of capra ibex, or bouquetin, and in that caſe that the diſſimilitude between the internal organization of the capra ibex and that of the common goat cannot be ſo very apparent as our author pretends. This is an intereſting point for the comparative anatomiſt to determine. An account was publiſhed in the French *Journ. de Phyſ.* for October 1786, to prove that the capra ibex ſometimes couples with the domeſtic goat, and produces mongrels. The fact was aſcertained by M. Berthoud van-Berchem who ſaw an inſtance of it in the Valais, where the inhabitants rear numerous herds of tame goats, and the bouquetin is found in a ſtate of nature among the mountains. It was long before well known that the goat will couple with ſheep, the hybrid produce of which differs very little from the natural offſpring of the ewe and ram, except in having a hairy inſtead of woolly fleece. We have yet to learn that an intermixture of the goat and ſheep may be productive of a breed of *fertile mules*, as Buffon ſeems to think very poſſible.

The hiſtory of the common goat has been very amply treated on by many writers, ſo that we can do little more than repeat the obſervations of others in this place.

The goat, in its domeſtic ſtate, is found in almoſt every part of the globe, bearing the extremes of heat and cold, and differing in form according to various circumſtances. It appears to have been originally confined to the old world, from whence it was tranſported to America. P. Browne ſeems to intimate that it is an aborigine of the iſland of Jamaica, but this is improbable: it is believed on very ſufficient authority that it was entirely unknown to the Americans till after the diſcovery of America, when it was introduced by the Europeans.

This animal, obſerves Buffon, is ſuperior to the ſheep both in ſentiment and dexterity. He approaches man ſpontaneouſly, and is eaſily familiarized; he is ſenſible of careſſes, and capable of a conſiderable degree of attachment; he is ſtronger, lighter, more agile, and leſs timid than the ſheep; he is a ſprightly, capricious, wandering, wanton animal. It is with much difficulty that he can be confined, and he loves to retire into ſolitude, and to climb, ſtand, and even ſleep on rugged and lofty eminences; he is robuſt, and eaſily nouriſhed, for he eats almoſt every herb, and is injured by very few; his bodily temperament, which in all animals has a great influence on the natural diſpoſition, is not eſſentially different from that of the ſheep. Theſe two animals, whoſe internal organization is almoſt entirely ſimilar, are nouriſhed, grow, and multiply in the ſame manner; and their diſeaſes are the ſame, excepting a few to which the goat is not ſubject. The goat fears not, like the ſheep, too great degree of heat; he cheerfully expoſes himſelf to the ſun, and ſleeps under its moſt ardent rays without being affected with the vertigo, or any other inconvenience; he is not afraid of rain or ſtorms; but he appears to feel the effects of ſevere cold. The inconſtancy of his diſpoſition is marked by the irregularity of his actions. He walks, ſtops ſhort, runs, leaps, approaches, or retires, ſhews, or conceals himſelf, or flies off as if actuated by mere caprice, and without any other cauſe than that which ariſes from an eccentric vivacity of temper; the ſuppleneſs of his organs, and the ſtrength and nervouſneſs of his frame, are hardly ſufficient to ſupport the petulance and rapidity of his natural movements.

"When paſtured along with ſheep, goats always take the lead of the flock. They love to feed ſeparately on the tops of hills, and prefer the moſt elevated and rugged parts of mountains. They find ſufficient nouriſhment in healthy, barren, and uncultivated grounds. They do infinite miſchief when permitted to go among corn, vines, copſes, or young plantations; for they eat with avidity the tender bark, and young ſhoots of trees, which generally proves fatal to their growth. They carefully avoid moiſt ground, marſhy meadows, and rich paſtures. They are ſeldom reared in plain countries, where they never thrive well, and where their fleſh is always bad.

The male goat is capable of engendering when he is a year old, and the female at ſeven months. But as the fruits of their early coupling are generally weak and defective, they are commonly reſtrained till they be eighteen months, or two years old. The he-goat is handſome, vigorous, and ardent, and one is ſufficient to accompany an hundred and fifty females for the ſpace of two or three months; but his ardour, which ſoon conſumes him, does not laſt more than three or four years, and by the age of five or ſix, he becomes nearly enervated. In the ſelection of a he-goat for propagation, attention ſhould be paid to his ſtrength and age; he ſhould be large, and about two years old; his neck ſhort and fleſhy; his head ſlender; his ears pendulous; his thighs thick; his limbs firm; his hair black, thick, and ſoft; and his beard long and buſhy. The choice of the female is of leſs conſequence, obſerving only, that thoſe with large bodies, thick thighs, who walk light, have large udders, and ſoft buſhy hair, are the moſt preferable. They are in ſeaſon from September to the end of November, though they will couple and produce young at all times. The ſmell of the goat is highly unpleaſant, that of the male eſpecially. During the months of September and October, the whole atmoſphere around them is filled with their ſtrong diſagreeable odour, and which, though as diſguſting as aſafœtida itſelf, in the idea of ſome naturaliſts, may perhaps be conducive to the prevention of many diſtempers, and to cure thoſe of a nervous and hyſterical kind. Horſes are ſuppoſed to be much refreſhed with it, on which account, many people keep he-goats in their ſtuds or ſtables.

The female produces one kid, ſometimes two, very rarely three, and never more than four: ſhe carries her young five months, bringing them forth about April; and is in condition to breed from the age of ſeven months till ſhe is ſeven years old. The he-goat, as before ſaid, will propagate as long, if proper care be taken of him, but otherwiſe becomes uſeleſs two or three years ſooner. He is then ſent to fatten among the common herd. The ſtrong ſmell of the goat does not proceed, it is ſaid, from his fleſh, but his ſkin. Theſe animals are ſeldom permitted to grow old, or perhaps they might live eleven or twelve years; but it is uſual to fatten and kill them as ſoon as they ceaſe to multiply, becauſe the older they are the worſe is their fleſh. The goats are animals that coſt very little for their food, and in cold, mountainous countries are attended with conſiderable advantage: their fleſh, tallow, hair, and ſkin, are all valuable commodities. Their milk is ſaid to be more wholeſome and better than that of the ſheep; it is uſed in medicine, curdles eaſily, and makes very good cheeſe. The females, ſays Buffon, will allow themſelves to be ſucked by infants, to whom their milk affords very excellent nouriſhment. "Like cows and ſheep, (continues this writer) they are ſucked by the viper, and alſo by the bird called in France l'engoulevent, (the goat-ſucker,) which faſtens to their teats during the night, and, as ſome ſay, makes them loſe their milk for ever after." It may be almoſt ſuperfluous to point out the abſurdity of this whimſical idea, founded, as we muſt believe, on the groſſeſt prejudices of ruſtic ignorance; this notion is certainly entertained among the lower claſs of peaſantry, both in our own country and in France. It is a matter of ſurpriſe to many, that Sonnini in his edition of Buffon's works, has not endeavoured to correct this error, or explain it to our ſatisfaction. The readineſs with which the female goat will allow herſelf to be ſucked by other animals, is indeed well known. Of this, Sonnini has given a very ſtriking inſtance; he aſſures us that in the year 1780, he ſaw a foal which had loſt its mother, nouriſhed by a goat, which during the proceſs, was placed on a barrel, in order that that the foal might ſuck with the greater convenience. The foal followed its nurſe to paſture, as it would its parent, and was attended with the greateſt care by the goat, which always called it back by her bleatings when it wandered to any diſtance from her.

The colour of the goat is various, being either black, brown, white, or ſpotted. Thoſe of Wales Mr. Pennant thinks far ſuperior in ſize, ſtrength, and fineneſs of the hair, to thoſe of other mountainous countries; the goats of France, and the Alps, being generally ſhort-haired, reddiſh, and ſmall-horned; while the horns of the Cambrian he-goat have been ſeen three feet two inches long, and branching three feet aſunder between the tips. "The ſuet of the goat is in great eſteem, as well as the hair. Many of the inhabitants of Caernarvonſhire ſuffer theſe animals to run wild on the rocks during winter as well as ſummer; and kill them in October, for the ſake of their fat, either by ſhooting them with bullets, or running them down with dogs, like deer. The goats killed for this purpoſe are about four or five years old. Their ſuet will make candles, far ſuperior in whiteneſs and goodneſs to thoſe made from that of the ſheep or the ox, and accordingly brings a much greater price in the market: nor are the horns without their uſe; the country people making of them excellent handles for tucks, and penknives. The ſkin is peculiarly well adapted for the glove manufactory, eſpecially that of the kid: abroad it is dreſſed and made into ſtockings, bed-ticks, bolſters, bed hangings, ſheets, and even ſhirts. In the army it carries the foot-ſoldier's proviſions. As it takes a dye better than any other ſkin, it was formerly much uſed for hangings in the houſes of people of fortune, being ſuſceptible of the richeſt colours; and when flowered and ornamented with gold and ſilver, became an elegant and ſuperb furniture." "The fleſh is of great uſe to the inhabitants of the country where it reſides, and affords them a cheap and plentiful proviſion in the winter months, when the kids are brought to market. The haunches of the goat are frequently ſalted and dried, and ſupply all the uſes of bacon: this by the natives is called *coch yr wden*, or hung veniſon."—"The meat of a ſplayed goat of ſix or ſeven years old (which is called *hyfr*,) is reckoned the beſt; being generally very ſweet and fat. This makes an excellent paſty; goes under the name of rock veniſon, and is little inferior to that of the deer. Thus nature provides even on the tops of high craggy mountains, not only neceſſaries, but delicacies for the inhabitants." Penn. Brit. Zool.

The above paſſages are ſelected from Pennant's deſcription of the Cambrian goats, as they contain much uſeful information. It ſhould, however, be mentioned, that thoſe obſervations were written above thirty years ago, and are not in every particular applicable to the preſent ſtate of things in Wales, where Engliſh manners, and Engliſh huſbandry are making rapid innovations. The goat is an animal, we may ſtrictly ſay from our own very recent obſervations, but ſparingly cultivated at this time in the principality. The culture of this uſeful animal has been on the decline for the laſt twenty years, and is now almoſt wholly confined to the mountainous parts of Caernarvonſhire: a ſmall breed of ſheep that thrive admirably well on the mountains, where goats were formerly kept, have ſuperſeded them: the rearing of cattle, and eſpecially ſheep, is conſidered more beneficial and reſpectable by the modern Welſh farmer. We have obſerved goats in greater numbers among the tremendous cliffs that overlook the paſs of Pont-Aberglaſslyn, than in any other parts of North Wales. In South Wales the goat is ſeldom ſeen.

The ſkin of the goat is readily converted into parchment, and it is alſo frequently uſed by the leather dreſſers for making what is termed Morocco leather: the beſt ſkins for this purpoſe are thoſe of the Corſican breed of goats. The manufacturer, we alſo learn, can imitate the chamois leather ſo exactly with the ſkin of the goat, that the difference is ſcarcely to be diſcerned.

Capra *Angorenſis*, γ. Body covered with very long, pendent, ſpirally curled hair.

*Capra Angorenſis*, Haſſelq.—*Chevre d'Angora*, Buffon, &c.—*Angora goat*, Pennant, &c.

The Angora goat is in general of a beautiful milk-white colour, with ſhort legs, and black ſpreading ſpirally twiſted horns. The hair on the whole body is diſpoſed in long pendent ſpiral ringlets; its ears are pendulous, and the horns of the female, inſtead of divaricating, as in the male, turn backwards, and are much ſhorter in proportion.

In its native country this animal is highly valued, and with ſufficient reaſon, for it is a ſource of riches to its cultivators; the fineſt, and moſt coſtly robes of the higheſt claſſes in Turkey being fabricated of its ſilky fleece: the price it bears is very great. Moſt of the European nations have agents for purchaſing the valuable wool of this animal, which the Turks, it is reported, will not allow to be ſent out of their empire in a raw ſtate, but in the form of thread; a multitude of the poorer orders obtaining a livelihood by ſpinning it. The moſt conſiderable manufactory of camlets, fabricated with this wool in Europe, appears to be thoſe of Liſle and Amiens, in France. In order to preſerve this beautiful hair in good condition, the goat herds of Angora are peculiarly careful of their flocks, waſhing and combing them with the greateſt diligence; and it is ſaid that a change of paſture frequently makes them loſe their beauty; this variety being naturally confined to narrow bounds, and produced only in the tract ſurrounding the towns of Angora and Beibazar, two places ſituated in a ſmall diſtrict of Aſia Minor, not far from Smyrna, and remarkable for producing a peculiar race of ſheep, cats, and rabbits, as well as goats, with hair of uncommon length and fineneſs.

Capra *Mambrica*, δ. Horns reclining; ears pendulous; chin bearded.

*Capra Mambrica*, Linn.—*Capra Syriaca*, Briſſ.—*Geyſſen mit hangenden Ohren*, Rauwolf.—*Chèvre Mambrine*, ou *chèvre du Levant*, Buff.—*Syrian goat*, Penn.

This variety of goat takes its name of Mambrica from a particular mountain, called Mambre, or Mambra, ſituated in the middle part of Paleſtine, near the river Hebron, where they abound. The variety is common in many parts of the Eaſt, and is principally diſtinguiſhed by the great length of the ears, which are pendulous, and ſometimes reach ſo low as to incommode the animal while feeding. It is reported by travellers, that the owners of theſe animals, on ſuch occaſions, cut off one of their ears that they may feed with greater eaſe. This, however, is denied by Sonnini and other French writers, who aſſure us that the ears of this goat never reach ſo low as the ground, and are never cut off. Its general colour is reddiſh, with ſhort blackiſh horns. This is the common goat of Aleppo, the inhabitants of which it ſupplies with milk. The ſame is the caſe at Cairo, where theſe goats are driven in ſmall flocks every morning through the different quarters of the city, and every one ſees taken from them the quantity of milk they want.

Capra *Depreſſa*, ε. Horns ſmall, depreſſed, and cloſely incumbent to the ſkull.

*Capra depreſſa*, Linn.—*Capra parva Americana*, &c. Briſſ.—*Bouc d'Afrique*, Buff. &c.—*African goat*, Penn.

This is a ſmall variety, or dwarf kind of goat, found in ſome parts of Africa. The French call the male bouc d'Afrique, and the female, la chèvre naine. This kind has rough hair, and extremely ſhort horns, which are very thick, triangular, and lie cloſe to the head; in the female they are ſtill ſhorter. Dr. Shaw obſerves, that Linnæus ſeems to have entertained an erroneous idea relative to the native country of this variety, and to have ſuppoſed it an American animal. We may add, that although the animal was originally a native of Africa, it has been long ſince tranſported to America, where it thrives well, and ſeems to have undergone no other alteration from the effect of its new climate, than in becoming ſomewhat more diminutive in ſize.

Capra *Reverſa*, ζ. Horns erect, and recurved at the tips. Linn.

*Ibex parvus Americanus*, Briſſ.—*Bouc de Juda*, *Chèvre de Juda*, Buff.—*Whidaw goat*, Penn.

Herds of this ſpecies of goat are cultivated in moſt parts of Upper Egypt. This is a dwarf variety, found in various parts of Africa. It is ſaid to be alſo very common in Guinea and Angola. The fleſh is conſidered as an excellent food.

There is a variety of this kind with longer horns; the hair is long and ſilky, and the whole animal bears ſome reſemblance to a ſmall Angora goat. Buffon deſcribes it as being conſiderably larger than the other, meaſuring two feet nine inches in length; while the other was only twenty-four inches long. Buff. Suppl. pl. 13.

Capra *Capricornus*, η. Horns ſhort, turned forwards at the tips, and annulated at the ſides.

*La capricorne*, Buff.—*Capricorn goat*, Penn.—*Capricorn goat*.

A variety deſcribed by Buffon from a ſkeleton with the horns, preſerved in the king's cabinet at Paris. The animal is ſuppoſed to be a native of Africa. In the form and proportion of the bones, Buffon tells us it bears a perfect reſemblance to the domeſtic he-goat; and the figure of the under jaw is the ſame as that of the wild goat; but that it differs from both in the horns; thoſe of the wild goat having prominent tubercles or knobs, and two longitudinal ridges, between which there is a well marked anterior face: thoſe of the common goat have but one ridge, and no tubercles. The horns of the capricon have but one ridge, and no anterior face; and though they want the tubercles, they have rugoſities, which are larger than thoſe of the male domeſtic goat. Theſe differences, adds Buffon, ſeem to indicate an intermediate race between the wild and domeſtic goat; and, beſides, the horns of the capricorn are ſhort and crooked at the point, like thoſe of the chamois; and at the ſame time are compreſſed and ringed; and hence, they ſeem to partake at once of the he-goat, the wild goat, and the chamois. This variety appears to be ſcarcely known, except from the deſcription of it given us by Buffon.

CAPRA-COTTA, in *Geography*, an inconſiderable town of Naples, in the county of Moliſe, ſeated on an eminence; 13 miles N.W. of Moliſe.

Capra *Saltans*, or Capræ *Saltantes*, in *Meteorology*, a fiery meteor, or exhalation, which ſometimes appears in the atmoſphere, and is not fired in a ſtraight line, but with inflexions, and windings in and out, reſembling the caperings of a goat. The capræ ſaltantes are not ſo called from their figure, which is various, ſometimes round, ſometimes long, but, from their moving by jerks, ſomewhat like the leaps of that animal; and from the little languets of fire which hang at, and ſometimes fall from them, which antiquity has been pleaſed to fancy like the beard or locks of a goat's hair. Ariſtotle diſtinguiſhes the capra from the trabs, in that the latter proceeds with an uniform motion, the former with an irregular one, and as it were by jumps. Ariſt. Met. lib. i. cap. 5. Mem. Ac. Inſer. tom. vi. p. 95.

The capræ ſeem to be very low, yet ſometimes fly ſo high, that meteorologiſts have placed them in the upper region, though not ſo conſtantly, but they are ſometimes alſo found in the middle region. Of globular capræ we have divers inſtances, in ancient as well as modern naturaliſts. Such was the flame ſaid by Seneca to have been ſeen in form of a huge ball, about the bigneſs of the moon, when Paulus Æmilius waged war againſt Perſeus. Such another, he tells us, was ſeen at the death of Auguſtus; another on the tragedy of Sejanus; another at the death of Germanicus. Such was that ſeen about Michaelmas, 1676, by no leſs than twelve counties at once; it is deſcribed by Mr. Naſh, as it appeared near Seighford in Staffordſhire, as of a globular figure moving by jerks, and making ſhort reſts at every one of them, letting fall drops of fire, which were parts of its body; for it decreaſed in magnitude the farther it went, and the oftener it dropped, till at length it wholly diſappeared. Senec. Nat. Quæſt. lib. i. cap. 1. Phil. Tranſ. N° 135. p. 865, ſeq. Plott. Nat. Hiſt. Stafford. cap. i. § 40.

Capra *Trituratoria*, in *Ancient Huſbandry*, was a kind of iron log, made in the figure of a goat, which was laid on the *tribula*, to make it more effectual in ſeparating the corn from the ears, the ancient way of threſhing.

CAPRAJA, in *Geography*, an iſland of the Mediterranean, ſituate between the coaſt of Italy and the northern part of the iſland of Corſica, about 6 leagues in circumference. This iſland is populous, though the ſoil is dry and mountainous. It is ſurrounded with rocks, except in one part, where is a good harbour, belonging to a town named Capraja. N. lat. 4[illegible]. E. long. [illegible] 5'.

CAPRARIA, in *Botany*, goat-weed, (from *caper*, a *goat*, ſo called becauſe goats are fond of the biflora, the beſt known ſpecies). Linn. Gen. 768. Schreb. 1030. Willd. 1169. Gært. 309. Juſſ. 118. Vent. ii. 557. Claſs and Order, *didynamia angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. Vent. *Scrophulariæ*, Juſſ.

Gen Ch. *Cal.* one-leafed, five-cleft, oblong; ſegments linear, erect, diſtant, permanent, ſhorter than the corolla. *Cor.* monopetalous, bell-ſhaped, five-cleft, nearly equal; ſegments oblong, acute; the two upper ones more erect. *Stam.* filaments four, awl-ſhaped, inſerted into the baſe of the corolla, and only the half of its length; the two lower ones rather ſhorter than the others; anthers heart-ſhaped. *Piſt.* germ conical; ſtyle thread-ſhaped, longer than the ſtamens; ſtigma heart-ſhaped, (bilamellate, Gært. two-lobed, Juſſ.) two-valved, equal. *Capſ.* oblong-conical, compreſſed at the tip, two-celled, two-valved; valves, when mature, bifid; partition doubled by the bending of the edges of the valves. *Seeds* numerous, roundiſh; receptacle adhering to the axis of the capſule, not to the partition; when mature, diſunited.

Eſſ. Ch. *Calyx* five-cleft. *Corolla* bell-ſhaped, five-cleft, acute. *Capſule* two celled, two-valved, many-ſeeded.

Sp. 1. C. *biflora*, Linn. Sp. Pl. 1. Willd. 1. Mart. 1. Lam. Enc. 1. Gært. tab. 53. *fig.* 9. Lam. Ill. Plant. 534. *fig.* 2. "Leaves alternate; flowers in pairs." A ſhrub, three or four feet high. *Branches* long, erect, commonly ſmooth. *Leaves* about an inch and half long, but in the ſhade near five, alternate, ſeſſile, oval-oblong, ſerrated in their upper half, ſmooth; on ſandy coaſts ſucculent, thick, and brittle. *Flowers* white, ſcentleſs, axillary, generally two together, ſometimes three; peduncles ſimple, ſhorter than the leaves; calyx ſmooth, deeply five-cleft; ſegments of the corolla hairy at the baſe; anthers double; germ egg-ſhaped, furrowed; ſtigma headed, acute. *Capſule* furrowed on both ſides, the length of the calyx. *Seeds* very ſmall. A native of the Weſt Indian iſlands, and the neighbouring continent, and one of the plants which the natives of the country uſe for tea. The capraria peruviana of Feuillé, (Per. i. p. 764. tab. 48.) which Linnæus conjectured to be this ſpecies, is a different plant, for which a diſtinct genus has been formed by Ruiz and Pavon, in their Flora Peruvienſis; but it differs from capraria only in having

five ſtamens. See Xuaresia. 2. C. *cruſtacea*, Linn. Mant. p. 87. Mart. 3. (Caranas, Rumph. Amb. v. p. 491. tab. 170. *fig.* 3. *β*. Capraria uniflora. Burm. Fl. Ind. p. 133. tab. 14. *fig.* 3.) "Leaves oppoſite, egg-ſhaped, ſcolloped, on very ſhort petioles." *Stems* herbaceous, much-branched, four or five inches high. *Leaves* oppoſite, rather acute. *Flowers* axillary and terminal; peduncles ſimple, longer than the leaves. Linnæus ſays that it reſembles his *capparis gratioloides*, but that the leaves are more egg-ſhaped and petioled. Willdenow has omitted it. 3. C. *lucida*, Willd. 2. Mart. 6. Hort. Kew. ii. p. 353. "Leaves oppoſite, oblong, acute, ſharply and minutely ſerrated, even; petioles winged; peduncles three-flowered." Whole plant ſmooth. *Stems* quadrangular, biennial. *Leaves* an inch and half long; petioles half an inch. *Flowers* axillary, a little longer than the petioles; exterior pedicels ſometimes three-flowered; bractes awl-ſhaped, the length of the pedicels; ſegments of the calyx awl-ſhaped, three lines in length; corolla ſalver-ſhaped; tube cylindrical, pale purple, a little longer than the calyx, gibbous on the outſide at the baſe, a little bent above, then erect, a little elongated on the outſide; border horizontal; ſegments egg-ſhaped, obtuſe, equal, reddiſh purple, with a dark purple ſpot near the throat; throat hairy; anthers oblong, compreſſed; germ roundiſh; ſtyle ſhorter than the ſtamens; ſtigma large, convex, oblique. Hort. Kew. Willdenow obſerves that the fruit is a two-celled berry, as it probably is in all the Cape ſpecies, ſince they agree with it in the habit of the flower; and that, therefore, they may not improperly form a diſtinct genus. A native of the Cape of Good Hope: obſerved by Maſſon. Introduced at Kew, in 1774. It flowers in April and May. 4. C. *lanceolata*, Linn. jun. Supp. 284. Willd. 3. Mart. 4. Hort. Kew. ii. p. 354. "Leaves oppoſite, lanceolate, entire; racemes compound, terminal." *Stem* ſhrubby. *Leaves* two inches long and more, acute, ſtiff. *Flowers* in a terminal panicle, compoſed of ſhort racemes. Found at the Cape of Good Hope by Thunberg and Maſſon. Introduced in 1774. 5. C. *ſemiſerrata*, Willd. 4. Vahl. Eclog. ii. p. 47*. "Leaves lanceolate, ſerrated outwards; peduncles ſometimes many-flowered." *Stem* herbaceous, erect, round below, angular above, interſperſed with ſhort hairs. *Leaves* two or three inches long, alternate, thick-ſet, ſpreading, narrowing at the baſe into the petiole, acute, ſmooth on both ſides, ſerrated from the tip to the middle, then entire. *Flowers* axillary, and terminal; peduncles ſcarcely half an inch long, pubeſcent, from one to four-flowered; pedicels alternate, approximate, very ſhort; bracte one at the baſe of each pedicel, linear-lanceolate, a little longer than the pedicel; ſegments of the calyx awl-ſhaped; corolla longer than the calyx, hairy at the bottom; ſegments five, linear-oblong; ſtigma capitate. *Capſule* oblong, a little longer than the calyx, two-furrowed, two-valved, ſplitting into two. *Seeds* numerous, very ſmall, affixed to a linear, looſe receptacle. Vahl. A native of St. Martha, in America. 6. C. *undulata*, Linn. jun. Supp. 284. Willd. 5. Mart. 5. Hort. Kew. ii. p. 354. L'Herit. Sert. Ang. p. 21. "Leaves oppoſite, oblong-egg-ſhaped, entire, waved; upper ones ſomewhat heart-ſhaped, in whorls; racemes reſembling ſpikes." *Stem* ſhrubby. Found at the Cape of Good Hope by Thunberg and Maſſon. Introduced in 1774. 7. C. *humilis*, Willd. 6. Mart. 7. Hort. Kew. ii. p. 354. "Pubeſcent; leaves oppoſite, or in threes, egg-ſhaped, ſerrated, petioled; peduncles axillary, ſhorter than the petiole." *Root* annual. Found in the Eaſt Indies by Dr. I. G. Koenig. Introduced in 1781, by ſir Joſeph Banks.

*Propagation and Culture.* The firſt ſpecies is propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring, and to bring them forward ſhould be afterwards planted upon another hot bed. About the middle or end of June they may be tranſplanted either into pots of rich earth, or into a warm border, where they will ripen their ſeeds in autumn in the open air. The Cape ſpecies may be increaſed by cuttings, and are leſs tender. Martyn's Miller.

Capraria *Gratioloides*, (Linn.) See Lindernia *pyxidaria*.

Capraria *Durantifolia*, (Linn.) See Stemodia *durantifolia*.

Capraria. (Linn. Hort. Cliff.) See Scoparia *dulcis*.

Capraria. (Gron. Virg.) See Lechea *minor*.

Capraria, in *Geography*, one of the Treniiti iſlands, in the Adriatic, about 4 leagues from the coaſt of Italy; very ſmall, and uninhabited. N. lat. 42° 10′. E. long. 15° 36′.

CAPRARIENSES, in *Ancient Geography*, an appellation given to mountains of Africa, in Mauritania, which were inacceſſible, and alſo to the inhabitants of theſe mountains.

CAPRASIA, a town of Italy, in Brutium.—Alſo, the name given by Pliny to one of the mouths of the river Eridanus, or the Po.

CAPRATA, in *Ornithology*, a ſpecies of Motacilla, of a black colour, with the rump, vent, and ſpot on the wing-coverts white.

Inhabits the iſland Luzonia. Length four inches and a half. Bill black; legs black-brown. Called by Briſſon *rubetra lucionenſis*, *traquet d'iſle de Luçon*, Buffon, and *Luzonian warbler*, Latham.

CAPREA, in *Zoology*. See Capriolus and Cervus.

CAPREÆ, in *Ancient Geography*. See Capri.

Capreæ, in *Entomology*, a ſpecies of Phalæna, (Noctua). The wings flexuoſe, cinereous, with three oblique whitiſh ſtreaks, and two ſtigmata. Inhabits Germany. Larva naked, green, and feeds on the willow.

Capreæ, that ſpecies of Aphis, that infeſts *ſalix caprea*.

This is ſmall, of a greeniſh colour, with pointed abdomen; and the eyes, antennæ, and tips of the legs black. Fabr. &c.

CAPREOLATE *Plants*, in *Botany*. See Capreolus.

CAPREOLI, in the *Ancient Architecture*, a ſort of rafters or timbers ſerving to ſuſtain the *canterii*, either in buildings, or machines. They were thus called, not, as Philander imagines, from their reſemblance to the *capreoli*, or tendrils of vines, but from the affinity of their form and office to wild goats; as theſe butt and repel things with their horns, ſo do the former oppoſe their heads or horns to the weight of the *canterii*.

CAPREOLUS, in *Botany*, a term uſed by the old botaniſts for a tendril, or claſper, called by Linnæus *cirrhus*.

Capreolus, in the *Ancient Huſbandry*, a kind of iron hoe or inſtrument with two forks or fangs, wherewith to ſtir and move the ground.

Capreolus, in *Zoology*, a ſpecies of Cervus, the roe of Engliſh writers. See Cervus.

CAPRI, in *Geography*, anciently Capreæ, an iſland of the Mediterranean, about three Italian miles from the coaſt of Naples, about eight miles in circumference. Although it is ſo mountainous that its coaſts are almoſt inacceſſible, ſome parts of it are very fertile; and it abounds ſo much with various birds of paſſage, and more eſpecially with quails, that the greateſt part of the biſhop's income ariſes from the taking of theſe and the hunting of other game. Hence this iſland has been called the "biſhopric of quails." Swinburne, (Travels, vol. iii. p. 7.) informs us, that even in bad years the number of quails caught in this iſland amounts to 12,000; and that in good years it exceeds 60,000. On the eaſtern ſummit of Capri are cliffs of ſtupendous altitude that overhang the channel, which ſeparates this iſland from Cape Campanella, anciently called "promontorium Athenæum, or Minervæ." The iſland of Capri or Capræ is famous in hiſtory as a place often viſited by the emperor Auguſtus both for health and recreation; and as the retreat of Tiberius, A. D. 27, who here abandoned himſelf to indolence, intemperance, and the moſt infamous debauchery. In this retired abode he ſpent a great part of ten years, ſecluded from the world, and wallowing in brutal debaucheries, the detail of which has been tranſmitted to us by many authors of unqueſtionable credit, although ſome of the practices which they recite ſeem to be incompatible with his advanced age and complicated infirmities: however, the obſcene ſculptures and medals, which have been dug up in almoſt every corner of the iſland, ſufficiently prove that the charge againſt him is well founded. On the ſcite of his ſummer palace now ſtands the hermitage of Santa Maria, commanding a moſt enchanting proſpect. Tiberius, in order to vary his pleaſures, and to enjoy the advantages as well as avoid the inconveniences of each revolving ſeaſon, built twelve villas in different ſituations, dedicated to the twelve greater gods, of ſome of which the ruins are ſtill to be ſeen. At Santa Maria are extenſive vaults and reſervoirs, and on an adjoining brow are the remains of a light-houſe; two broken columns indicate the entrance of the principal court. At the palace of La Marina, Tiberius had a winter reſidence; where columns and other fragments of architecture ſcattered on the ſands remain as memorials of its ſplendour. A ſemicircular receſs of net-work, the "opus reticulatum" of Vitruvius, raiſed againſt the cliff, ſeems to have been a part of the theatre; and the conduit that ſupplied the palace with water ſtill exiſts. The ruins ſtretch far into the ſea, which has now reſumed the territory from which it had formerly been expelled by terraces and piers. Here the ſoil is richly vegetative, and compoſed of divers layers; a deep ſtratum of good mould covers a yellow bole, under which lies a ſtone exactly ſimilar to the tufa of the volcanic hills round Naples. The palace was built with this ſtone, but in the abutments and back walls are inſerted large pieces of lava in a rough ſtate of torrefaction, like that of the cruſt of Veſuvian ſtreams when cooled; yet the upper rocks of Capri are univerſally calcareous, and homogeneal with the ſtrata of the Sorrentine mountains, of which they appear to have been a part till ſplit aſunder, and caſt off by an earthquake that buried the intermediate grounds in the ſea. Theſe lower tracts in Capri have probably been thrown up by fire in the midſt of lime-ſtone mountains, in the ſame manner as the plain of Sorrento. According to Dion Caſſius, this iſland was wild and barren before the Cæſars took it under their protection; at this day a large portion of its ſurface is uncultivated and impracticable; but every ſpot that will admit the hoe is induſtriouſly tilled, and richly laden with the choiceſt productions of agriculture. The odium attached to the memory of Tiberius proved fatal to his favourite abode. Scarcely was his death proclaimed at Rome, ere the ſenate iſſued orders for the demolition of every fabrick he had raiſed on the iſland, which, by way of puniſhment, was thenceforward deſtined to be a ſtate-priſon. The wife and ſiſter of Commodus were baniſhed to its inhoſpitable rocks, which were ſoon ſtained with their blood. In the middle ages Capri became an appendage of the Amalfitan republic, and, after the downfal of that ſtate, belonged to the duchy of Naples. About a ſtone's throw from the ſouth ſide of this iſland are two or three pointed rocks, the "Scopuli Sirenum," mentioned by Virgil and Ovid in their deſcription of Æneas's voyage.

"This iſle," ſays Swinburne, "reunites ſuch a variety of beauties and advantages, that it is a matter of wonder to me, why ſo few of our miſanthropic countrymen reſort to it; a man of an indolent philoſophic caſt would here be ſuited with a ſcene for meditation and ſolitary enjoyment; the temperature of the air and the excellence of the fruits would ſecure his health; and the delightful ſcenery round him would diſpel his cares, and given an even cheerful flow to his ſpirits."

Capri, a town of the iſland above deſcribed, ſeated in a narrow, low, but delightful and fertile ſpot of land, between two rugged eminences, which form the extremities of the iſland, and appearing at a diſtance by its cupolas and buildings to be a conſiderable place, but on a nearer approach dwindling to a village. It is the ſee of a biſhop, ſuffragan of Amalfi. It is 17 miles S. of Naples. N. lat. 30° 34′. E. long. 13° 58′.

Capri *Portus*, in *Ancient Geography*, a port of Macedonia, which, according to Mela, lay between mount Athos and the river Strymon.

CAPRIANUS *Mons*, a mountain of Sicily, in the vicinity of the town of Heraclea.

CAPRIATA, Pier-Giovanno, in *Biography*, an hiſtorian of Genoa, who flouriſhed in the 17th century. His Italian hiſtory comprehends the tranſactions that occurred in Italy during his own time, which he has related with clearneſs, and with ſagacity traced to their cauſes; maintaining at the ſame time, as he ſays, a perfect impartiality between the powers of France and Spain, that were concerned in them. The two firſt parts of this hiſtory were publiſhed by Capriata in his life-time, from 1613 to 1644; and the third part, extending to 1660, was publiſhed by his ſon after his death. The whole has been tranſlated into Engliſh. Gen. Dict.

CAPRICCIO, *Ital.* a muſical term for a wild, irregular movement, but full of fire and fancy. It is generally intended to diſplay execution in the performance of new and ſingular paſſages, with the freedom of an extemporaneous flight. During the laſt century, the capriccj of Vivaldi, Veracini, and Locatelli, were in high favour.

Caprice is applied, in *Architecture*, to an edifice of a ſingular taſte, and deviating much from the common rules of building.

CAPRICERVA, in *Zoology*, one of the ſynonyms of *antilope cervicapra*; which ſee.

CAPRICKE, in *Geography*, a town of France, in the department of Eſcaut, and chief place of a canton, in the diſtrict of L'Ecluſe. The place contains 3239, and the canton 14,049 inhabitants. The territory comprehends 125 kiliometres and 8 communes.

CAPRICORN, the *Goat*, in *Aſtronomy*, a ſouthern conſtellation and the tenth ſign of the zodiac, from which alſo the tenth part of the ecliptic takes the ſame denomination. This was one of the 48 conſtellations received from the Egyptians by the Greeks.

The character whereby Capricorn is repreſented in aſtronomical writing, is ♑, or ♑, of which the other is an imitation. The former is a kind of reſemblance of the crooked horns of the goat, and the latter of the animal itſelf.

As to the figure of this conſtellation, the Greeks pretend that Pan, in order to avoid the terrible giant Typhon, threw himſelf into the Nile, and was changed into this figure; and that, in commemoration of this exploit, Jupiter took it up into heaven. But it is more probable, as Macrobius obſerves, that the Egyptians marked the portion of the heavens appropriated to this ſign, where the ſun begins to aſcend towards the north, with the figure of a goat, which is an animal that delights in climbing the ſides of mountains.

The ancients accounted Capricorn the tenth ſign, and when the ſun arrived thereat, it made the winter ſolſtice, with regard to our hemiſphere; but the ſtars having advanced a whole ſign towards the eaſt, Capricorn is now rather the eleventh ſign; and it is at the ſun's entry into Sagittary, that the ſolſtice happens: though the ancient manner of ſpeaking is ſtill retained.

The ſtars in the conſtellation of Capricorn, in Ptolemy's and Tycho's Catalogue, are 28; in that of Hevelius 29; though it is to be obſerved, one of thoſe in the tail, of the ſixth magnitude, marked in Tycho's book the twenty-ſeventh, was loſt in Hevelius's time. Mr. Flamſteed, in the Britannic Catalogue, enumerates 51 ſtars in this ſign.

It is repreſented on ancient monuments, medals, &c. as having the fore-part of a goat, and the hind-part of a fiſh; which is the form of an ægipan; and ſometimes, ſimply, under the form of a goat.

For Dr. Herſchel's account of the luſtre and magnitude of the ſtars in Capricorn, ſee Phil. Tranſ. vol. lxxxvi. p. 199. 217. vol. lxxxvii. p. 299.

CAPRICORN, *tropic of*, a leſſer circle of the ſphere, parallel to the equator; paſſing through the beginning of Capricorn, and determining the winter ſolſtice, or the point of the ſun's greateſt ſouth declination. See TROPIC.

CAPRICORN *beetle*, in *Entomology*, the trivial Engliſh name of *Cerambyx longimanus*, which ſee.

CAPRICORN-*goat*, in *Zoology*. See CAPRA *Capricornus*.

CAPRICORNE, the name given by Buffon, and other French writers, to *Capra capricornus*, which ſee.

CAPRICORNUS, a variety of the goat, *Capra ægagrus*, with ſhort horns, that turn forward at the apex, and are annulated at the ſides. See CAPRA.

CAPRICORNUS *exiguus ſaltatorius* of Ray, is the Fabrician inſect *Chryſomela hyoſcyami*. Mordella ovata cærulea nitida, tibiis ferrugineis. Linn. Faun. Suec. 540.

CAPRICORNUS *niger cornutus*, Muſ. Petrop. 652, is *Cerambyx batus* of Linnæus.

CAPRICORNUS *ruſticus* of Petiver, the inſect called by modern entomologiſts *Cerambyx ædilis*.

CAPRIFICATION, a name given in the iſlands of the Archipelago to a peculiar method of propagating and ripening the fruits of the domeſtic fig-trees, by means of inſects. Plin. Hiſt. Nat. lib. xv. cap. 19.

M. Tournefort aſſures us, that this method is ſtill practiſed every year in moſt of the Grecian iſlands; and he admired the patience of thoſe who ſpent above two months in carrying the flies from one fig-tree to another. Caprification is formed from *caprificus*, the wild fig tree, from whoſe fruits the inſects are produced, which are the chief inſtruments of caprification. This tree bears three different ſpecies of fruit, called *fornites*, *cratirites*, and *orni*, which anſwer no other purpoſe but that of facilitating the above operation. The *fornites* appear in Auguſt, and contain little worms, hatched from eggs depoſited by flies; in October and November, theſe worms become flies, which pierce the ſecond figs called *cratirites*, which do not appear till the end of September: theſe figs continue to the month of May following, and furniſh a lodgment for the eggs of the ſecond claſs of flies. In May, the third ſpecies of figs, called *orni*, appear; and when they are grown to a certain ſize and begin to open at the eye, they are pierced by the flies produced by the *cratirites*, or winter-figs. When the worms bred in theſe ſpring figs are transformed into flies, which happens in the months of May or July, the peaſants gather them, and tranſport them to the garden fig-trees. The ſucceſs of the caprification depends on this circumſtance, and therefore they viſit their wild fig-trees and their garden fig-trees every morning, to examine the eye of the fig; by which they judge when the flies are about to iſſue from the wild figs, and when they may be applied ſo as to pierce the garden figs. They are then depoſited on ſuch trees as are fit to receive them, and enter the fruit by the eye, where they lay eggs, the worms of which cauſe the garden-figs to attain their proper degree of bigneſs and maturity. The conſequence of this operation is, that garden fig-trees, which would ſcarcely yield twenty-five pounds of ripe figs, and fit for drying, yield two hundred and eighty pounds.

As to the manner whereby the puncture of the flies contributes to the maturation of the fruit, poſſibly it may be by lacerating the veſſels, and extravaſating the nutritious juice when they depoſit their eggs; with the egg they may alſo convey ſome liquor which gently ferments with the juice of the fig, and ſoftens its pulp. Even the Provence and Paris figs ripen much ſooner by wounding their buds with a ſtraw or feather dipped in oil-olive; plums and pears alſo wounded by inſects are found to ripen the ſooneſt, and in theſe the pulp about the wound is more exquiſite than the reſt. Mem. Acad. Scienc. ann. 1705, p. 447, ſeq.

Olivier, in "Nouveau Dictionaire d'Hiſtoire Naturelle," ſpeaks of this practice as merely the effect of a vulgar error ſanctioned by its high antiquity, and aſſerts that, after a long reſidence in the iſlands of the Archipelago, he is convinced of its futility. Caprification, he obſerves, is unknown in many countries of the Eaſt, has not been adopted in France, Italy, or Spain, and has lately been diſcontinued in ſeveral iſlands of the Archipelago, where it was formerly in uſe, and yet, nevertheleſs, good figs are produced in all theſe countries. The aſſiſtance of the Cynips, or fig-fly, he alleges, cannot be neceſſary to render the young germs fertile, ſince each fig contains near its eye a ſufficient number of male flowers to impregnate all the female ones within its cavity; and that if it were neceſſary, the pollen of the wild fig tree, which is ſuppoſed to be conveyed by the fly to the germs of the cultivated kind, could not fecundate, at the ſame time, thoſe which have attained to a conſiderable ſize, and thoſe which have but juſt, or have not yet appeared, and which do not ripen till two months afterwards. In anſwer to the latter part of the objection, it may, however, be remarked, that Tournefort particularly mentions the ſtrict attention paid by the Greek peaſants to the exact time when the orni of the wild ſhould be placed upon the garden fig-tree, and that every part of the crop muſt be ſuppoſed to have the needful ſupply at its proper ſeaſon. We may alſo add, that the reaſoning employed by Olivier does not at all apply to Tournefort's conjecture concerning the proximate cauſe of the effect produced. The proper queſtion to be conſidered is not whether the fig can produce fertile ſeed without the aid of the fly; of that no well-informed naturaliſt will entertain a doubt; but whether the fruit of the cultivated tree is increaſed in ſize, and heightened in flavour, by the operation. But ſtill it may be aſked, why does not the puncture made by the fly occaſion a ſimilar extravaſation of the nutritious juice of the wild fig, or convey to it the ſame fermenting liquor, and thus improve its native qualities? The ſubject, it muſt be acknowledged, is attended with difficulties which have not yet received a ſatisfactory ſolution. But it ſurely is an unwarrantable degree of ſcepticiſm, on account of theſe, to diſcredit the relations of able obſervers, founded on the experience of ages. Olivier refers to ſome intereſting and inſtructive memoirs publiſhed by Bernard on this ſubject, which we have not at preſent an opportunity to conſult.

Caprification is alſo applied, in a leſs proper ſenſe, to the art of propagating the palm-tree. Act. Erudit. Lipſ. 1721, p. 84.

CAPRIFICUS, in *Botany*, the name of the wild fig-tree.

CAPRIFOLIA, the third order of the eleventh claſs of Juſſieu's natural ſyſtem. It has the following characters: *Calyx* one-leafed, ſuperior, often calyceled, or bracteated at its baſe. *Corolla* generally monopetalous, either regular, or irregular; in a few inſtances polypetalous, petals united by a broad baſe. *Stamens* of a definite number, often five; in the monopetalous genera always inſerted into the corolla, and alternating with its ſegments; in the polypetalous ones ſometimes placed upon the piſtil, alternating with the petals, and ſometimes fixed to the middle of each petal. *Germ* inferior; ſtyle generally ſingle, ſometimes none; ſtigma ſingle, or rarely three. *Fruit* inferior, either a berry, or a one or many-celled capſule; each cell with one or many ſeeds. *Corculum* of the ſeed in a large upper cavity of the large, ſolid periſperm. *Stem* either a ſhrub or a tree; rarely herbaceous. *Leaves* in moſt, oppoſite; in a few, alternate; ſtipules none.

It is divided into four ſections: 1. Calyx calyceled, or bracteated; ſtyle ſingle; corolla monopetalous. Linnæa, trioſteum, ovieda, ſymphoricarpos, diervilla, xyloſteum, and caprifolium. 2. Calyx calyceled or bracteated; ſtyle ſingle; corolla ſubpolypetalous. Loranthus, viſcum, rhizophora. 3. Calyx bracteated; ſtyle none; ſtigmas three; corolla monopetalous. Viburnum, hortenſia, ſambucus. 4. Calyx ſimple; ſtyle ſingle; corolla polypetalous. Cornus, hedera.

CAPRIFOLIACEÆ, the third order of the eleventh claſs of Ventenat's natural ſyſtem, with the ſame characters, diviſions, and genera, as the Caprifolia of Juſſieu, except that Ovieda and Hortenſia are omitted. The plants of this family are generally reckoned aſtringent.

CAPRIFOLIUM, a name given by the old botaniſts to ſeveral plants which Linnæus afterwards placed in his genus Lonicera. Tournefort confined the term to ſuch ſpecies as have their flowers in heads, with an irregular two-lipped corolla. Juſſieu and Ventenat extend it to all that have flowers in heads, or in axillary, ſix-flowered whorls, including thoſe with a corolla nearly regular, the Periclymena of Tournefort. Gærtner ſeems to have comprehended under his Caprifolium, the whole Linnæan genus Lonicera, having reſtored the latter name to the Loranthus of Linnæus, ſome of whoſe ſpecies had been called Lonicera by Plumier and others. The name, it may be allowed, was changed by Linnæus without ſufficient reaſon; but Gærtner has in fact only increaſed the confuſion, in attempting to remove it.

CAPRIGLIA, in *Geography*, a town of Naples, in the province of Principato Ultra, 13 miles S. of Benevento.

CAPRIMA, in *Ancient Geography*, a ſmall town of Aſia Minor, placed by Diodorus Siculus in Caria.

CAPRIMULGUS, in *Ornithology*, a genus of the order Passeres, the *goatſucker* of the Engliſh, and *l'engoulevent* of French authors. The character of the genus conſiſts in having the bill ſlightly curved, very ſmall, ſubulate, and depreſſed at the baſe; mouth extremely large, and fringed at the ſides with a ſeries of briſtles; ears ample; tongue ſhort and very entire; tail not forked, and containing ten feathers; legs ſhort; middle claw with a broad ſerrated edge. Thus far we follow Gmelin, but we have to obſerve, that, although this definition of the Caprimulgus genus is applicable to moſt of the ſpecies, there are ſome with which it will not agree. In Caprimulgus grandis and jamaicenſis, for example, the claw of the middle toe is not ſerrated, and it is ſuſpected there are other ſpecies deſcribed, on the teſtimony of foreign authors, that are deſtitute of this Gmelinian character. Gmelin coincides with Latham in conſidering the entire figure of the tail as an eſſential character of the genus, but there are ſpecies known that have the tail furcated, and others that contain twelve feathers in the tail inſtead of ten, which latter is conſidered by both thoſe writers as an eſſential criterion, amongſt others, of the Caprimulgus genus. The ſpecies deſcribed are 21 in number.

Caprimulgus *grandis*, the *grand goatſucker* of Latham. *Ibijau, Caprimulgus americanus*, Ray. *Le grand ibijau*, and *Crapaud volant de Cayenne* of Buffon. This is ſpecifically diſtinguiſhed by being of a blackiſh colour, variegated with white and yellow; beneath white and black varied; area of the eyes yellowiſh; legs white. Lath. Ind. Orn. Blackiſh, varied with minute brown ſpots and ſtreaks; middle claw not ſerrated. Gmelin.

This gigantic ſpecies of goatſucker was ſuppoſed to be the largeſt of its race till the recent diſcovery of Caprimulgus megacephalis in the Auſtralaſian regions, and was therefore named ſpecifically *grandis*. It is nearly the ſize of a ſmall buzzard, meaſuring 23½ inches in length. The bill, which is three inches long, is covered nearly to the tip with hairs, that completely conceal the noſtrils. The plumage is blackiſh, varied principally with whitiſh and cream-coloured ſpots and marks on the upper parts of the body. The wings are brown on the outer edge; ſcapular feathers chiefly white; quills deep brown, ſlightly barred with white on each ſide, and the ſhafts black. The wings reach almoſt to the end of the tail, which laſt is 11 inches in length, rounded at the extremity, and of a brown colour, with ſeven or eight narrow dotted bars of white. Its legs are brown, and covered nearly to the toes with feathers; middle claw not ſerrated. Inhabits Cayenne, where it is ſaid to ſecrete itſelf within the hollow of ſome decayed tree in the day-time, eſpecially ſuch as ſtand near the water. Willughby's figure of the great ibijau is copied from one given by Marcgrave, that is not very remarkable for its accuracy, both a *creſt* and *horn* being erroneouſly repreſented on its head. There is a ſpecimen of this bird in the Leverian muſeum.

Caprimulgus *megacephalis* of Latham, *l'engoulevent mégacéphale* of Viellot. A ſpecies ſuperior in ſize to Caprimulgus grandis, lately diſcovered in New South Wales. The length of this bird is 28 inches. General plumage blackiſh brown, variegated and ſtreaked with yellowiſh and dull white; breaſt dirty-ferruginous; belly pale-aſh; wings and tail ſpotted, and banded alternately with black and whitiſh. The head and neck appear of a large ſize from the abundance of feathers with which thoſe parts are covered. The bill remarkably ſtronger than any other of the goatſucker tribe, its colour pale brown, and fringed at the baſe with a ſeries of feathers, much longer than the reſt, that ſtand nearly erect, and form a kind of creſt. The legs are yellowiſh.

Caprimulgus *Jamaicenſis*, the *Jamaica goatſucker*. The plumage of this ſpecies is ferruginous, ſtreaked with black: wings variegated with white; quill-feathers brown, with white ſpots; tail barred with black. Lath. Ind. Orn. *Caprimulgus Jamaicenſis*, Gmel. *Guira querea*, Ray, Buffon, &c. and *Mountain owl* of Brown.

This kind, though inferior in ſize to the former ſpecies of goatſucker, is a large bird, being about a foot and a half in length. Sloane deſcribes it in his hiſtory of Jamaica, but miſtakes it for a kind of wood owl, and Brown has fallen into a ſimilar error. The bill is of a black colour, and much bent downwards at the tip, correſponding in this particular with the lower mandible, which is alſo bent in the ſame direction, and cloſe exactly together when the mouth is ſhut; the noſtrils are covered with feathers. The irides are reddiſh-yellow, and the eyes are ſurrounded with a diſk of feathers not unlike thoſe of the owl tribe, and which appear to have deceived both Sloane and Brown. The upper parts of the head, neck, and body are compoſed of a mixture of ferruginous and black, ſtreaked longitudinally; the wing-coverts are partly brown, of a deep caſt, and partly ferruginous and fuſcous varied, and irregularly dotted with blackiſh, and ſome of the inner ones with a mixture of white. The quills are of a deep black brown, marked on the outer edge with eight or nine white ſpots. Its tail is ſeven inches long, cinereous, dotted with black, and croſſed with ſeven or eight bars of black brown. The legs rather large, feathered to the toes, and armed with black claws, the middle one of which, as in the former bird, is not ſerrated. This ſpecies, as its name implies, is a native of Jamaica, where it is reported to be uncommon; it inhabits woods, and feeds principally on inſects.

Caprimulgus *griſeus*, *grey goatſucker*. General colour grey; wings black, with pale grey lines; tail browniſh grey with fuſcous lines. Gmel.

A ſpecies thirteen inches in length, that inhabits Cayenne: the bill is of a brown colour above and yellow beneath; tail five inches in length, and ſcarcely extending beyond the length of the wings when the bird is at reſt. Buffon, who deſcribes this ſpecies, calls it *l'engoulevent gris*.

Caprimulgus *carolinenſis*, *Carolina goatſucker* of Cateſby, a kind diſtinguiſhed by having the upper part of the plumage waved with grey and blackiſh; beneath reddiſh-grey, with ſmall blackiſh lines; three exterior tail-feathers white on the inner edge. Ind. Orn. "Supra lineis tranſverſis angulatis alternis atris et griſeis varius, ſubtus ex rufo griſeus lineis nigricantibus longitudinalibus, cauda griſeo atro cancellata." Gmel. We have adopted Dr. Latham's ſpecific character of this bird, in preference to that of Gmelin, as being moſt expreſſive. The ſpecies inhabits Virginia and Carolina, and, like the reſt of the goatſuckers, appears only on the wing in the evening, or when the ſky is obſcured with heavy clouds preceding rain. The North Americans, it appears from Brown and other writers, call it the rain-bird, in alluſion to the latter circumſtance. It is the ſhort-winged goatſucker of the Arctic Zoology.

This does not exceed the common European goatſucker in point of ſize. The bill is duſky; upper parts of the head, neck, and body tranſverſely variegated with zig-zag alternate lines of duſky-brown and grey; the crown has alſo ſome ſpots of the latter colour, and on the wings are both ſpots and longitudinal yellowiſh and duſky ſtreaks. The ſides of the head, and all the under parts, are rufous-grey, marked with longitudinal blackiſh lines; from the gape of the mouth along the jaw on each ſide is a white ſtreak; and beneath this are a few yellowiſh ſpots; quills barred with duſky and grey, and ſpotted on the outer webs with yellow; on the inner web of the three firſt is a large white ſpot. The tail is four inches long, of a grey colour, with duſky bands and lines; legs brown, claws black, the middle one ſerrated. This bird is ſaid to lay its eggs on the ground, and it appears they very much reſemble thoſe of the lapwing.

Caprimulgus *Guianenſis*, the *Guiana goatſucker*. Colour tawny, ſtreaked and ſpotted with rufous; beneath the throat a white lunar band. *Le montvoyau de la Guiane, et Tette-chevre roux de la Guiane* of Buffon.

This kind, which inhabits Guiana, is nine inches in length. The bill is about three quarters of an inch in length, and is beſet with briſtles. The general colour of the plumage fulvous, with an irregular mixture of rufous throughout; on the top of the head, and hind part of the neck the ſtreaks are longitudinal, but on the upper part of the back oblique, as well as mixed with ſpots of an irregular ſhape on the reſt of the upper parts. Beneath, the plumage much reſembles that above, but the ſpots or markings are moſtly placed in a tranſverſe direction. From the gape ariſes a white band, which paſſes along the jaw and under the throat. The quill-feathers are black, the firſt five or ſix marked with a white ſpot. Tail three inches long, and extending an inch beyond the wings when they are cloſed. This bird, we are informed, is frequently obſerved to repeat the three ſyllables *mont-voy-au* very diſtinctly, when flying abroad at twilight in ſearch of prey.

Caprimulgus *rufus*, the *rufous goatſucker*, *l'engoulevent roux de Cayenne* of Buffon, and *Crapaud-volant, ou Tette chevre de Cayenne*, Pl. Enl. The ſpecies is diſtinguiſhed by being of a rufous colour, varied with black in longitudinal ſtreaks; wings, and lower part of the body faſciated with blackiſh; quill-feathers varied with rufous and black, in alternate ſtripes.

Somewhat larger than the foregoing ſpecies, being ten inches and a half in length. It inhabits Cayenne. The bill is of a pale brown colour; the irides yellow; and the plumage varied as before obſerved, with rufous, black, and a few white ſpots. The throat is marked tranſverſely with lines; the lower part of the body is alſo lineated, but the lines increaſe in breadth as they paſs backwards, the upper part of the belly is blackiſh, the lower rufous. The tail is banded with black, and exceeds the wings by half an inch. The legs are fleſh colour.

Caprimulgus *Europæus*, the *European goatſucker*. The colour black, varied with cinereous, fuſcous, ferruginous, and white; beneath reddiſh-white, with fuſcous bands. "Niger, cinereo, fuſco, ferrugineo et alba varius, narium tubis obſoletis." Linn. Fn. Suec. *Nocturnal goatſucker*, Pennant.

The European goatſucker, as it is generally called, is a native of Aſia and Africa, as well as Europe. Its length is ten inches and a half. The plumage is of a deep blackiſh colour, beautifully ſpeckled and diverſified with ſpots of grey, ferruginous, and white. The tail is four inches long; the legs ſhort, rough, or ſcaly, and feathered much below the knee; the toes connected together on each ſide by a ſlight membrane, and the middle claw ſerrated. The plumage of the male is brighter than in the female, and it is beſides known by having an oval white ſpot on the inner webs of the three exterior quill feathers, and another at the tip of the outer feathers of the tail.

A variety of this ſpecies is reported to have been brought from China by Sonnerat. This was rather larger, and the colours ſomewhat darker, than in our common kind; the feathers of the wings were black, marked with yellow ſpots, each incloſing a black dot in the centre, and the whole were ſo diſpoſed, that, at the firſt glance, the wings appeared to be marked tranſverſely with ſeven alternate bands of yellow, and the like number of black ones.

Fern-owl, churn-hawk, dorr-hawk, and night-jarr are the moſt familiar provincial names of this common goatſucker in various parts of England. Latham calls it the European goatſucker, this being the only bird of its genus that is found in Europe. It commonly arrives in England the latter end of May, and remains in the ſouthern parts of the iſland till about the end of September. In its paſſage from the eaſtward, it viſits Malta, and the ſouth of Europe, a month ſooner than England; and it is ſeldom earlier than October that it quits France; they have been ſeen in that country till

November. Some French authors aſſure us, that ſeveral birds of this ſpecies have been ſhot in the woods of Voſges in the middle of winter, but ſuch occurrences are very rare. The ſpecies has been recently obſerved in Siberia and Kamtſchatka, where it lives not only in foreſts but alſo in open countries, where it finds rocks, or high banks, for ſhelter. With us it lives in woods, and feeds on inſects, which it collects on the wing, in the duſk of the evening and morning, like the owl, and remains ſecreted, like that nocturnal bird, in the hollow of a tree, or ſome dark receſs, during the day-time. By chance, however, it has been noticed on the wing in the day-time when diſturbed in very gloomy weather. It is a great deſtroyer of the cockchafer-beetle, many of which, with other inſects, are uſually diſcovered in its ſtomach on diſſection. The note of this bird is ſingular, reſembling the noiſe of a large ſpinning-wheel, or as ſome liken it to that of the letter R frequently repeated, and which it is ſaid to emit only when perched on the branch of a tree, with its head hanging down in the duſk of the evening. Beſides this, it has a ſharp ſqueak, which is ſuppoſed to be its call of love, as the male is obſerved to utter it when in purſuit of the female. Its manner of perching is curious, for it almoſt conſtantly places itſelf longitudinally upon the branch, inſtead of acroſs, like other birds. The goatſucker was accuſed by the ancients, and many of the elder writers, of ſucking the teats of goats, and it is from this vulgar prejudice its popular name of goatſucker is derived; this abſurd notion, though countenanced by Buffon, is juſtly exploded by all modern authors. The female makes no neſt, but lays her eggs upon the bare ground, or looſe crags, without any apparent care; they are uſually two in number, of a white colour, and blotched with bluiſh brown.

Caprimulgus *Virginianus*, *Virginian goatſucker.* Colour brown, varied with grey and reddiſh; beneath reddiſh-white, tranſverſely ſtreaked; chin with a triangular white ſpot; area of the eyes and neck above ſpotted with orange.

This is ſmaller than the European goatſucker, its uſual length being eight inches, but ſhould the *moſchito-hawk* of Hudſon's bay, deſcribed on the authority of Mr. Hutchins by Latham, in his Supplement, prove to be the ſame bird as is generally ſuſpected, it ſometimes attains to the length of nine inches and a half. All the upper parts of the body are of a dull brown, tranſverſely variegated and blended with rufous brown, and an intermixture of aſh-colour, with a ſlight proportion of grey on the wings; on the chin is a white triangular ſpot, mottled with orange at the under part. The quills are duſky, the firſt five marked with a white ſpot about the middle; tail marked ſimilar, the two outer feathers with a ſpot of white near the extremity; legs fleſh-colour, middle claw ſerrated.

During the ſummer, this bird inhabits Virginia, where it firſt arrives about the middle of April, and frequents the mountainous parts, but will frequently approach the houſes in the evening, when it commonly ſettles on a rail or poſt, and cries for ſeveral times together very loud, ſomewhat like the word *whiperiwhip*, or *whip-poor-will*, pronouncing the firſt and laſt ſyllables loudeſt. The noiſe of this bird, which is both loud and diſagreeable, continues oftentimes the whole night, and it not unfrequently happens that four or five birds of the ſame ſpecies keep in company, and cry in concert together. They ſubſiſt chiefly on inſects. The eggs are of a greeniſh colour, with duſky ſpots and ſtreaks. Kalm ſpeaks of the fleſh of this bird as an article of food.

Linnæus appears to have conſidered this as a variety of the common or European goatſucker, *Caprimulgus Europæus β*. Both Cateſby and Buffon call it *whip-poor-will*, in alluſion to its note; it is the long-winged goatſucker of the Arctic Zoology, and Virginia goatſucker of Latham.

Caprimulgus *vittatus*, *ſtriped goatſucker*, and *l'engoulevent a bandes noires* of Viellot. A new ſpecies recently diſcovered in New Holland, where the Engliſh ſettlers call it the moſquito hawk. This bird is about nine or ten inches in length; the upper part of the head and neck are black, with a ſtripe of the ſame colour paſſing, in the form of a creſcent, behind the eyes. The black ſtripe on the upper part of the neck deſcends on each ſide to about the middle, where it divides into two diſtinct branches. Thoſe parts of the head whare the black does not appear is of a pale carnation or fleſh colour. The upper portion of the neck, with the body beneath, are of a ſomewhat ſimilar colour, but more inclining to ferruginous. Under the eyes, ſides of the neck, and upper part of the wings are marked with ſpots and vermicular lines; back and wing-coverts obſcure blue, ſpeckled with black; quills blackiſh, ſpotted and edged with ruſt-colour; tail-feathers dark brown ſpotted with ferruginous, and ſlightly forked; bill large, and of a black colour; legs reddiſh fleſh colour.

Caprimulgus *albicollis*, *white-throated goatſucker* of Latham. The plumage is rufous brown, varied with white and blackiſh ſtreaks; beneath browniſh with black lines; a triangular white ſpot on the throat; tail ſomewhat cuneated.

Length ten inches and a quarter; bill brown with the tip black, and the noſtrils rather prominent; head ſtreaked with black, upper parts of the body the ſame, but more obſcure; the ſcapulars, and moſt of the outer wing coverts have a black band near the end, and the tips yellowiſh buff-colour; leſſer quills ſpotted with rufous cream-colour on the outer web, the greater duſky black, and croſſed about the middle with a white bar; tail ſomewhat wedge-formed, the third feather white, ſecond white within and black without, the outermoſt with a white ſpot near the baſe; legs brown; middle toe very long, and greatly ſerrated. Deſcribed by Dr. Latham, from a ſpecimen in the collection of general Davies, that is ſuppoſed to have come from Cayenne.

Caprimulgus *ſemitorquatus*, *white-collared goatſucker* of Latham, is deſcribed on the authority of Buffon, who calls it *le petit engoulevent de Cayenne*; Gmelin calls it *ſemitorquatus*. This bird is blackiſh, varied with rufous and grey, with a white lunule on the lower part of the collar. Length eight inches, and inhabits Cayenne.

Caprimulgus *Braſilianus*, *Braſilian goatſucker.* Plumage yellowiſh black, varied with white ſpecks; beneath varied with black and white; area of the eye yellowiſh white.

Size of a ſwallow. Bill and eyes blackiſh; wings and tail even; legs white, the middle claw ſerrated at the outer edge; tail expanſile. This, as the name implies, inhabits Brazil.

Caprimulgus *acutus*, *ſharp-tailed goatſucker*, and *l'engoulevent acutipenne de la Guyane* of Buffon.

This kind is readily diſtinguiſhed by the pointed tips of the tail-feathers from the reſt of the ſpecies in the ſame tribe; the plumage is blackiſh, faſciated above with grey, and beneath with rufous; head and collar reddiſh brown. It inhabits Guiana, and is about ſeven inches and a half in length. The ſhafts of all the tail-feathers are bare of webs at the tips; bill and legs black.

Caprimulgus *Cayennenſis*, *Cayenne*, or *white-necked goatſucker*. Plumage rufous and grey, varied with black undulated lines; throat and ſtripe on the wing white; temples rufous, with five black ſtreaks. *Caprimulgus cayanus*, Latham.

Deſcribed on the authority of Buffon, who calls it *l'engoulevent de Cayenne*, as being ſeven inches and a half in length. Bill black, irides yellow; head and neck tinged with rufous; lower part of the belly ſpotted with black; two middle feathers of the tail grey, croſſed with five or ſix blackiſh bands; the reſt black, bordered with white; legs yellow brown. This bird inhabits Cayenne, where it is found in the plantations, and when on the wing is ſaid to utter a weak cry, which has been compared to that of the toad, and it has alſo another note that ſomewhat reſembles the barking of a dog. It is not a timorous bird by any means, neither is it a rare ſpecies.

Caprimulgus *Americanus*, *American goatſucker*, diſtinguiſhed ſpecifically, according to Gmelin, by having the noſtrils very prominent and cylindrical. The plumage is variegated with black, grey, and obſcure brown.

This is a Linnæan ſpecies, *Caprimulgus Americanus* of that naturaliſt. Ray calls it the ſmall wood-owl, as does likewiſe Sloane, in his Hiſtory of Jamaica; it is *l'engoulevent à lunettes, ou le haleur* of Buffon, and other French authors. This bird is ſeven inches in length; the bill black, and beſet with briſtles; the noſtrils projecting about one-eighth of an inch; legs and claws grey. Like the reſt of its tribe, this kind feeds on inſects. It is found in various parts of America.

Caprimulgus *Novæ Hollandiæ*, *creſted goatſucker* of Phillips' Voyage to Botany bay. This is of a brown colour, clouded with black and whitiſh, and whitiſh beneath; neck and breaſt with duſky bands; creſt on the front erect and ſetaceous.

Inhabits New Holland, and is rather ſmaller than the European goatſucker. The length is nine inches and a half. Its bill is black; gape wide, and yellowiſh within; behind the baſe of the upper mandible ariſes a creſt of twelve briſtles, which are thinly bearded at the ſides; quill-feathers brown, the five or ſix exterior ones with whitiſh ſpots on the outer ſide; tail rounded, fuſcous, with twelve whitiſh bands clouded with blackiſh; legs rather long and yellow.

Caprimulgus *Aſiaticus*, *Aſiatic goatſucker*, or *Bombay goatſucker* of Latham. Plumage pale-aſh, clouded with black and ferruginous; breaſt banded with cinereous; crown with a blackiſh ſtreak, and a pale ſpot on the jaws and chin.

This ſpecies was firſt deſcribed by Dr. Latham, from a ſpecimen in the poſſeſſion of ſir Joſeph Banks, in the Supplement to his Synopſis of Birds. It is, he ſays, the ſize of the Virginia goatſucker: length eight inches and a half. Bill duſky; general colour of the plumage not unlike that of the Siberian owl, being a beautiful mixture of pale aſh colour, mottled with duſky down the middle of the crown; on each ſide of the under jaw is a pale ſtreak; and on the throat a whitiſh ſpot; the breaſt croſſed with numerous cinereous bars; between the legs pale rufous; the quills are duſky, barred with rufous; the firſt ſhorteſt; four of the greater quills have a ſpot of white on the inner web; the tail marked the ſame, but the two middle tail-feathers are likewiſe mottled, as the back; the two outer ones on each ſide have the ends white for about an inch, but the white extends higher up on the outer webs; the middle toe is greatly pectinated. Inhabits Bombay. Lath. Suppl.

It ſeems this bird has been alſo diſcovered in Africa by le Vaillaint, who names it *l'engoulevent muſicien*, in compliment to its note, which he obſerves is both piercing and melodious, contrary to what has been advanced by an Engliſh writer (Dr. Latham), who aſſirms that its noiſe is horrible. It has the ſame manners of life as the European goatſucker.

Caprimulgus *Indicus*, *Indian goatſucker*. Colour pale aſh, tranſverſely lineated with black; cheeks, breaſt, and wings ſpotted with ferruginous; tail-feathers bluiſh, faſciated with black, the exterior one varied with ferruginous and black.

Latham deſcribes this ſpecies, in his Supplement of Birds, as a native of India, on the authority of lady Impey, without mentioning its ſize. Another account is given of it by Viellot, a French naturaliſt, under the name of *l'engoulevent cendré, rayé de noir*, but which is a literal French tranſlation of the following deſcription. "Crown and back whitiſh aſh-colour, elegantly marked with minute duſky lines; cheeks, breaſt, wing-coverts, and ſecondaries beautifully marked in the ſame manner with lines and large ſpots of ruſt; prime quills duſky; middle feathers of the tail light aſh, croſſed with a few black bars; outermoſt feathers ruſty and black."

Caprimulgus *torquatus*, *gold-collared goatſucker*. This is an inhabitant of Braſil, and is about the ſize of the common lark. The plumage is cinereous-brown, varied with whitiſh and dull yellowiſh ſpots; on the hind head a golden ring; two middle tail-feathers longeſt.

Though the body of this bird is ſcarcely larger than a lark, its length of wings and tail is conſiderable. The upper mandible of the bill is hooked, and beſet at the baſe with ten or twelve thick briſtles; eyes black, head large, flat, and broad. The two middle tail-feathers are eight inches in length, but the reſt are ſhorter; legs duſky, with black claws, the middle one of which is ſerrated. This is called by Briſſon *Tette-chevre du Breſil;* and *Le petit engoulevent tacheté de Cayenne* by Viellot.

Caprimulgus *longipennis*, *Leona goatſucker* of Shaw, Nat. Miſc. A native of Sierra Leona. Size of a ſtarling. The plumage is grey, variegated; wings ſpotted with rufous and black; on each ſhoulder a long naked-ſhafted feather.

Viellot deſcribes this curious bird under the title of *l'engoulevent de Léone*, after Dr. Latham, who very lately publiſhed an account of it, in which he names it *Caprimulgus macrodipterous*. The French author, Viellot, gives it as a new ſpecies, on the authority of Latham; from which we may preſume he was either not aware of its having been previouſly deſcribed by Dr. Shaw, as above mentioned, or did not think proper to acknowledge the circumſtance.

CAPRIOLES, derived from *capreolus*, a diminutive of *capra*, *goat*, in *Horſemanſhip*, are leaps which a horſe makes in one and the ſame place, without advancing forwards; and that in ſuch manner that when he is in the air, at the height of his leap, he yerks or ſtrikes out with his hind-legs as near and even together, and as far out as he can ſtretch them; in which action, he clacks, or makes a noiſe with them.

The capriole is the moſt violent of all the high-raiſed airs: there are ſeveral kinds of caprioles; as a *right capriole, back capriole, ſide capriole, broken capriole*, the *open capriole*, &c.

To make this air perfect, the horſe ſhould raiſe his fore parts and his hinder to an equal height; and when he ſtrikes out behind, his croupe ſhould be on a level with his withers. In riſing, and in coming down, his head and mouth ſhould be quite ſteady and firm; and he ſhould preſent his fore head quite ſtrait: when he riſes, his fore-legs ſhould be bent under him a good deal, and equally. When he ſtrikes out with his hinder legs, he ought to do it nervouſly, and with all his force; and his two feet ſhould be even, of an equal height, and their action the ſame: laſtly, the horſe ſhould, at every leap, fall a foot and a half, or the ſpace of two feet diſtant from the ſpot from which he roſe. In order to make caprioles, it is not abſolutely neceſſary that a horſe ſhould paſs through *curvets* and *balotades;* becauſe ſome horſes are naturally more light and active in their loins than ſtrong, and which are brought to leap with more difficulty, than to the other airs in which their ſtrength muſt be much more united, and their diſpoſition attended to; but nevertheleſs it is certain, that if the horſe is brought to riſe by degrees, and is worked in the intermediate airs, before he undertakes the caprioles, he will not weaken and ſtrain himſelf ſo much, and will be ſooner confirmed in his leſſons, than one which begins at once with the caprioles. The motions of a horſe, when he makes a perfect capriole, have an effect directly oppoſite to that of peſades and curvets. Theſe two airs are proper to aſſure the head of the horſe, and to make it light, and this by ſo much the more as the principal action depends upon the haunches, and a moderate appuy of the mouth; but caprioles are apt to give too great an appuy, becauſe the horſe, when he makes the ſtrongeſt action of his air, that is, when he ſtrikes out as he is coming to the ground, is entirely ſupported by the hand; therefore, before he is put to leap, he ought to have a perfect appuy, and his ſhoulders ſhould at leaſt be ſuppled and lightened, by having made peſades; and he ſhould be without fear, anger, or any kind of uneaſineſs, becauſe, by leaping, he acquires a knowledge of his own ſtrength and power, and he may apply it to bad purpoſes, to free himſelf from obedience, and to indulge his caprice and ill humour. Some horſes have a diſpoſition to this air, and ſufficient ſtrength to go through it; but their mouths are ſo delicate, ſenſible, and averſe from the hand, that you cannot ſupport them without hindering them from advancing: hence it follows, that their action before is cold and ſlow, and never ſufficiently high, and they cannot be carried forward when they raiſe their croupe, and ſtrike out; and it is impoſſible to keep them firm as they come down. To remedy this, begin their leſſon upon the trot, and preſs them in it ſo ſmartly, as to make them often go into the gallop; obſerve a medium, in order to ſave their ſtrength and vigour, that they may furniſh as many leaps as are requiſite to the perfection of the air. Purſue the ſame courſe with a horſe that is too ſtrong, and who retains and avails himſelf of the ſtrength of his back, ſo as not to make his leaps freely and readily; by this means you will abate his ſuperfluous vigour, which ſerves only to diſunite and make him troubleſome. It is uſual to ſupple a horſe that is light in the hand by means of the trot, before you teach him to leap; but a contrary method muſt be obſerved with thoſe which are heavy and clumſy, or that pull upon the hand. Gallop and trot them; and this exerciſe will take away all fear of the aids and corrections, and the following day they will preſent themſelves more freely and willingly. Inſtead of trying to correct the horſe, which pulls upon the hand, compel him to make ſome caprioles with his face to the wall, and keep him up to it cloſer, or farther off, as you find him heavy, or endeavouring to force the hand; and by this method you will conſtrain him to ſhorten his leaps, and to be more attentive to his buſineſs. If he abandons himſelf, or bears too hard upon the hand, hold him firm at the end of his leap, and in the inſtant when his feet are coming to the ground, yield your hand immediately to him, and he will abandon himſelf much leſs upon the bit. If he retains himſelf, and hangs back, eaſing your hand to him will not alone be ſufficient; but to make him advance, you muſt puſh him to his bit, by aiding him briſkly, and in time, with your legs.

To dreſs a horſe to the caprioles, the pillars may be employed, or they may be diſpenſed with. When the pillars are uſed, tie him to them, make him keep up to his bit properly, or what is called "fill up the cords," and endeavour, by little and little, to make him riſe before, taking care to make him bend his knees, and gather up his legs, as much as you poſſibly can. For this purpoſe, uſe your ſwitch briſkly; for if you can teach him to bend his legs well, his manege will be much more beautiful, and he will be much lighter in the hand. When the fore-part has been thus gained, put him in the pillars again; ſhortening the cords, in order to make him raiſe his croupe from the ground, and yerk out equally, and, at the ſame time, with both his hinder legs, which he muſt be taught to do, by attacking and ſtriking him upon the croupe with the ſwitch or chambriere. When he is able to riſe before and laſh out behind, let him be taught to unite theſe two times, and perform them together. Let him then be mounted, and always in the pillars; and let the rider ſupport him in the hand, and put him to make one or two leaps, without leaning upon the cords of the caveſon, in order that he may learn to take a juſt appuy, and to feel it. As ſoon as he begins to know and obey the hand, he ſhould be aided gently with the calves of the legs, ſhould be ſupported, and you ſhould "pinch" him delicately and finely with both ſpurs. If he anſwers once or twice to theſe aids, without loſing his temper, or being angry, you will have great reaſon to expect that he will ſoon furniſh his leaps equally and juſtly, with reſpect to the hand and heel. When he has been ſo far advanced by means of the pillars, walk him ſtrait forward a certain ſpace; and if he does not offer to riſe of himſelf, try to make him. If he himſelf takes the right time, ſeize the moment, avail yourſelf of it, and let him make two, three, or four caprioles, or one or two, as you may judge it neceſſary. By letting him thus walk calmly and quietly, in a ſhort time he will, of himſelf, begin to make caprioles ſtrait forward; but in caſe he ſhould diſcover any ſigns of reſiſtance to the hand or heel, or the other aids, recourſe ſhould be had immediately to the caveſon and pillars. The method, now deſcribed, of adjuſting and dreſſing a horſe for caprioles, by means of the pillars, is very dangerous in itſelf, and capable of ſpoiling and making a horſe become deſperate and ungovernable, unleſs it be practiſed by perſons of conſummate ſkill and experience.

Mr. Berenger prefers the following method, which, though more difficult and painful to the horſe, is better and more ſure. Having well exerciſed the horſe in "peſades," walk him ſtrait forward, keeping him "together," and ſupporting him ſo as to hold and keep him in the hand, but not ſo as to ſtop him entirely. After this, ſtrike him gently with the end of the ſwitch upon his croupe and buttocks, and continue to do it till he lifts up his croupe and kicks. Then careſs him, and let him walk ſome ſteps, and then attack him again, not minding to make him riſe before, nor hindering him from it, if he offers ſo to do. Remember to encourage and coax him every time that he anſwers to the aids, and obeys. When he is thus acquainted with the aid of the ſwitch, let him make peſades of a moderate height, ſtrait forward, and at the ſecond or third, attack him behind with your ſwitch, to make him laſh out. If he obeys, make him riſe "before" again in the minute that his hinder legs come to the ground, in order to make him furniſh two or three peſades, to work his haunches. After this, coax and careſs him without letting him ſtir from the place, if his appuy be firm and good; and in caſe it is hard, make him go backwards, or if it is light and juſt, let him advance quietly and ſlowly. To enable him to make his leaps juſt, and to know the exact time of making them, no attention ſhould be given to the number of peſades he makes before or after his leap, but at the moment when you feel him prepared, and whilſt he is in the peſade, aid him briſkly behind; letting him, in the beginning, not riſe ſo high "before," when you intend he ſhould yerk out behind, as he would, were he only to make a peſade, that ſo his croupe may be more at liberty, and he may yerk out with greater eaſe. In proportion as his croupe becomes light and active, you may raiſe his fore-part higher and higher, and ſupport it while in the air, till he makes his leaps true, and in juſt proportion. When theſe leſſons have been ſufficiently practiſed, you may retrench by degrees the number of the peſades, which ſeparated and divided the leaps. You may now demand of him two leaps together; and from theſe you may come, with patience and diſcretion, to three, or from three to four leaps; and, laſtly, to as many as he can furniſh in the ſame air and with equal ſtrength. Remember always to make him finiſh upon his haunches; and this is the only ſure way of preventing all the diſorders a horſe may be guilty of from impatience and fear. Some horſes will leap very high, and with great agility ſtrait forwards, which, when put to leap upon the voltes, uſually loſe their natural grace and beauty, for want of ſtrength and not being equal to the laſh, in which all their motions are forced and conſtrained. If a horſe has a firm appuy and ſtrength ſufficient to furniſh this air upon the voltes, begin by making him know the ſpace and roundneſs of the volte to each hand; let him walk round it in a ſlow and diſtinct pace, keeping his croupe very much preſſed and confined upon the line of the volte, which ought to be much larger for this air than for "croupades" and "balotades." When this is done, make him riſe, and let him make one or two caprioles, followed by as many peſades; then walk him two or three ſteps upon the ſame line; then raiſe him again, ſupporting him more and more, and keeping him even upon the line of the volte, ſo that it may be exactly round, and confining his croupe with your outward leg. If this leſſon be given with judgment, your horſe will ſoon make all the "voltes" in the ſame air; and to make him furniſh a ſecond, as ſoon as he has cloſed and finiſhed the firſt, raiſe him again, and without letting him ſtop, get from him as many leaps as you can, working him always upon the volte, in which he walks and leaps alternately, till he cloſes and ends it with the ſame vigour and reſolution as he did the firſt. Aid always with the outward rein, either upon the voltes, or when you leap ſtrait forward, you will narrow and confine the fore-parts, and enlarge the hinder parts, by which means the croupe will not be preſſed, but free and unconſtrained. See Curvets and Voltes. The ſureſt way to ſucceed, when you undertake to dreſs a horſe to caprioles, is to arm yourſelf with an invincible patience, and to prefer for this purpoſe ſuch horſes as have a diſpoſition, are active, light, and have a clean ſinewy ſtrength, to ſuch as are endowed with greater ſtrength and force; for theſe laſt never leap regularly, and are fit for nothing but to break their riders' backs, and make them ſpit blood, by their irregular, violent, and unexpected motions. Berenger's Hiſt. and Art of Horſemanſhip, vol. ii. ch. 20.

CAPRISCUS, in *Ichthyology*, a ſpecies of Balistes, that inhabits the Indian, Mediterranean, and American ſeas. It is ſpecifically diſtinguiſhed by having the dorſal ray ſerrated in front; ventral ſingle and low; tail rounded; ſnout ſomewhat obtuſe. Gronov.

This is capriſcus of Artedi and others, caper of Renard, and poupou-noble of Renard. It is an intereſting ſpecies, and has the body variegated with many colours.

Capriscus, is alſo the name given by Klein to Balistes Monoceros, which ſee.

CAPRONE, in *Geography*, one of the Greek iſlands N.W of Stanchio, larger than Capra, and near it. See Capra.

CAPRONEZA, a ſmall town of Hungary, in Sclavonia; 12 miles from the Save.

CAPROTINA, in *Mythology*, a name given to Juno by the Romans, in commemoration of a ſingular event recorded in the Saturnalia of Macrobius, l. i. c. 12. After the Gauls had quitted Rome, the neighbouring people took the advantage of their departure, and of the exhauſted ſtate of the republic, and beſieged the city under the conduct of Lucius, dictator of the Fidenates. They demanded of the Romans the ſurrender of their wives and daughters. The ſlaves, in conformity to the counſel of one of them, named Philotis, aſſumed the habits of their miſtreſſes, and preſented themſelves to the enemy; who, conceiving them to be the Roman females whom they had demanded, diſtributed them through their camp. Under the pretence of celebrating a feaſt, they induced the officers and ſoldiers to drink freely; and when they were all aſleep they gave a ſignal to the city by means of a wild fig, called in Latin "caprificus." The Romans ruſhed ſuddenly upon their enemies, filled their camp with carnage, and gave liberty to their ſlaves, together with a ſum of money at their marriage. They inſtituted alſo a feaſt to Juno, who in reference to the wild fig, was ſurnamed "Caprotina." The day on which Rome was thus delivered, and which was the nones of July, was called the "Caprotine" nones. This ſingular victory is mentioned by Plutarch and Arnobius.

CAPROTINIA, feaſts of Juno Caprotina, which were celebrated on the 9th of July, in favour of the female ſlaves. During this ſolemnity they ran about beating themſelves with their fiſts and with rods. None but women aſſiſted in the ſacrifices offered at this feaſt.

CAPRUS, in *Ancient Geography*, a river of Aſſyria, which, as well as the Gorgus, are ſuppoſed to have flowed between the two cities of Nineveh and Seleucia. Theſe two rivers are now called, as ſome have ſuppoſed, the Great Zab and Little Zab. Thevenot calls theſe rivers Zarb, but ſpeaks only of one, which he ſaw fall into the Tigris: he calls it a large river, making it half as broad as the Tigris, and obſerves, that it is very rapid, that its water is whitiſh, and very cold; which he would ſeemingly account for by its falling from the mountains of Curdeſtan, and being merely ſnow-water.

CAPSA, or Capse, now *Gafsa*, one of the ſtrong cities of Jugurtha, in Africa, concerning the ſituation of which authors are diſagreed. Ptolemy places one Capſa in the ancient Bizacium, upon a ſmall river which falls into the gulf which is formed by the river Triton at its mouth; and the Itinerary of Antonine marks it between Telepte and Tacapé, ſo that this Capſa was north of that which Salluſt mentions. The latter Capſa of Salluſt and of Ptolemy is placed in Numidia, amidſt the deſerts, and its foundation is aſcribed to Hercules the Libyan. It was taken by Marius, according to the relation of Florus; and Oroſius ſays, that it was full of royal treaſures. This city was deſtroyed in the war of Cæſar againſt Scipio. Dr. Shaw (Trav. p. 124.) places Capſa or Gafſa 12 leagues to the S.E. by E. of Ferreanah (the ancient Telepté); and he infers from ſome imperfect inſcriptions that preſerve the ancient name of the city, as well as that of "Jugis Aqua," particularly deſcribed by Salluſt, and appropriated to Capſa, that the Capſa of Salluſt and Ptolemy were the ſame; though Bochart and Cellarius have ſuppoſed the contrary. This Capſa was formerly encircled by ſtrong walls, towers, and baſtions; but it was taken and demoliſhed by Occuba, a famous Arab general. The walls of the citadel are ſtill remaining, as monuments of its ancient glory and ſtrength, 24 fathoms in height and 5 thick, built of large ſquare ſtones, which have now acquired the ſolidity and firmneſs of a rock. The walls of the town were rebuilt by the inhabitants ſince their firſt demolition; but were afterwards deſtroyed by Jacob Almanzor, who ſent a governor and troops into the province. In Marmol's time Capſa was very populous, abounding with ſtately moſques and other ſtructures of ſuperb and regular workmanſhip; but it is now occupied by an indigent people, fleeced and oppreſſed by the Tuneſe government. It is built on a riſing ground, and near it are plantations of palms, olives, piſtachios, and other fruit trees, beyond which, occupying a ſmall extent, is an interchange only of barren hills and valleys. The water which refreſhes theſe plantations ariſes from two fountains; the one within the citadel, the other in the centre of the city. The latter, ſuppoſed by Dr. Shaw to have been the "Jugis Aqua" of Salluſt, (Bell. Jugurth. § 94.), and the "Tarmid" of Edriſi, (Geog. Nub. p. 86.) was formerly covered with a cupola. It is ſtill walled round, and diſcharges itſelf into a large baſon, deſigned originally for a bath. This fountain and the other unite before they leave the city, and form a pretty large brook, which, from the quantity of the water, and the rapidity of the ſtream, might continue its courſe to a great diſtance, were it not conſtantly employed and imbibed in the uſes above-mentioned. The climate and inhabitants of Capſa are unhealthy. Both men and women dreſs handſomely, except their feet, which they cover with coarſe ſhoes of bungling workmanſhip, and made of the rough ſkins of wild beaſts, equally inconvenient and unbecoming. The authors of the Modern Univerſal Hiſtory, (vol. xiv. p. 281, 8vo.) ſay, that its moſt probable ſituation is in N. lat. 33° 15′. and E. long. 9° 3′, 30 leagues from Teuſera.

Capsa, in *Geography*, a town of European Turkey, in Romania.

CAPSARIUS, from *capſa*, *ſatchel*, in *Antiquity*, a ſervant who attended the Roman youth to ſchool, carrying a ſatchel with their books in it, ſometimes alſo called *librarius*.

Capsarius was alſo an attendant at the baths, who took charge of the veſtments of thoſe by whom they were frequented. The Capſarii, it ſhould ſeem, at leaſt in the latter days of the empire, had an officer particularly placed over them for the ſummary adminiſtration of juſtice. Dig. lib. i. tit. 15. § 3. Adverſus capſarios quoque, qui mercede ſervanda in balneis veſtimenta ſuſcipiunt, judex eſt conſtitutus: ut ſi quid in ſervandis veſtimentis fraudulenter admiſerint, ipſe cognoſcat.

Capsarius, from *capſa*, *cheſt*, among the Roman *Bankers*, was he who had the care of the money cheſt, or coffer.

CAPSCHAC, or Kipschak, in *Geography*, a conſiderable country of Tartary, which extends to Europe and Aſia, between the Jaick and the Nieper. It is the country from which the Coſſacks ſprung. It abounds in grain and cattle; and is ſubject to a khan and ſeveral other princes. The people are warriors. Its capital is Serai.

CAPSELLA, in *Botany*, a name given by Cæſalpinus to *thlaſpi burſa paſtoris* of Linnæus, propoſed by Juſſieu, and received by Ventenat as a diſtinct genus, becauſe it differs from the other ſpecies of thlaſpi, in having a triangular, or rather inverſely heart-ſhaped, ſilicle without a border.

CAPSICUM, Guinea pepper, (doubtful whether derived from *καπτω*, *to bite*, on account of the biting heat of the ſeed and pericarp, or from *capſa*, *a cheſt*, alluding to the form and ſtructure of the pericarp.) Linn. Gen. 252. Schreb. 338. Willd. 384. Tourn. Inſt. p. 152. Pl. 66. Gært. 773. Lam. Illuſt. 326. Juſſ. 126. Vent. ii. 374. (Pimento. Encyc. and Nouv. Dict.) Claſs and order, *pentandria monogynia*. Nat. Ord. *Luridæ*, Linn. *Solaneæ*, Juſſ. Vent.

Gen. Ch. *Cal.* perianth one-leafed, five-cleft, or five-toothed, erect, permanent. *Cor.* monopetalous, wheel-ſhaped; tube very ſhort; border five-cleft, ſpreading, plaited; ſegments broad. *Stam.* five, awl-ſhaped, very ſmall; anthers oblong, converging. *Piſt.* germ egg-ſhaped; ſtyle thread-ſhaped, longer than the ſtamens; ſtigma obtuſe. *Peric.* a dry berry, of different ſhapes, two or three-celled, hollow, coloured; receptacles adhering to the partition, dry. *Seeds* numerous, kidney-ſhaped, compreſſed.

Eſſ. Ch. *Corolla* wheel-ſhaped. *Berry* dry. *Seeds* compreſſed. Nearly allied to ſolanum, but differs from it in having a dry, not pulpy pericarp, in the pungent, burning taſte of its ſeeds; and in its general habit, which is ſo much alike in all the ſpecies, that it is not eaſy to give them deciſive ſpecific characters. The great variety that is found in the form and colour of the fruit increaſes the difficulty, and makes it almoſt impoſſible to determine, in many caſes, which are the diſtinct ſpecies, and which are only varieties. Linnæus, in his Species Plantarum, acknowledged only two ſpecies, one annual, the other ſhrubby, with a variety diſtinguiſhed by its ſmall, red, conical fruit. This variety he made a diſtinct ſpecies in his firſt Mantiſſa and Syſtema Naturæ, and added another with a ſomewhat ſhrubby, quadrangular ſtem. The old botaniſts mention many kinds. Miller has ten ſpecies, beſides varieties; but ſeveral of his ſpecies are now eſteemed only varieties. Six of them are herbaceous and annual; at leaſt, as he found by experience, they are ſuch in our ſtoves, their ſtems decaying ſoon after the fruit is ripe; but it may be doubted whether ſome that are perennial in their native climates, may not become annual under our artificial treatment. In the enumeration of ſpecies, we ſhall take La Marck and Poiret for our guides.

Sp. 1. C. *annuum*, Linn. Sp. Pl. Gært. tab. 132. *fig.* 2. Woodville Med. Bot. tab. 144. (Piper Indicum vulgatiſſimum, Bauh. Pin. 102. Vallia-capo-Molago, Rheed. Mal. ii. tab. 35.) "Stem herbaceous; peduncles ſolitary; fruit oblong." *Root* fibrous. *Stem* one to four or five feet high, nearly ſimple, round, a little ſtriated, ſmooth. *Leaves* egg-ſhaped, acuminate, entire, petioled, placed in no regular order; petioles long, flexible, generally ſmooth, but ſometimes, as well as the ſtem, a little pubeſcent. *Flowers* white, lateral; peduncles long. *Fruit* ſmooth and ſhining, very variable in its form and colour; in ſome inſtances long, ſtraight, acute; in others ſhort, thick, obtuſe, and even emarginate at its ſummit: in ſome red; in others yellow; and ſometimes both colours on the ſame plant; in ſome, according to Miller, upright; in others pendant, which has induced us to omit the word pendant, inſerted by La Marck in the ſpecific character, although thoſe plants in Miller's poſſeſſion, which had upright fruit, may poſſibly belong to one of the following ſpecies. A native of the Eaſt and Weſt Indies. 2. C. *fruteſcens*, Linn. Sp. Pl. Lam. Ill. tab. 116. *fig.* 2. (C. braſilianum, Cluſ. Exot. 340. *fig.* 2. C. indicum, Rumph. Amb. tab. 38. *fig.* 3. C. ſiliqua olivæformi, Tourn. Inſt. 153.) "Stem ſhrubby; leaves lanceolate; fruit oblong, ſolitary, rather erect." *Stem* a little rough, nearly round, and like the other parts of the plants, a little pubeſcent; branches numerous, ſtiff, angular. *Leaves* alternate, or two together, or oppoſite to the young branches, lanceolate-egg-ſhaped, or acuminate, with yellowiſh nerves underneath, on ſhort petioles. *Flowers* ſmall, white, or yellowiſh, placed a little above the axils of the leaves; peduncle long, almoſt ſtraight, thread-ſhaped, thickened at the top when the fruit ripens, as in all the other ſpecies; calyx almoſt truncate, with five very ſhort teeth; ſegments of the corolla almoſt lanceolate, acute, ſpreading. *Fruit* oblong, obtuſe, the form and ſize of a ſmall olive, reddiſh yellow. A native of the Indies, and the iſle of Ceylon. 3. C. *ceraſiforme*, Lam. Illuſ. Willd. (Piper ſiliqua parva, J. Bauh. ii. p. 944, Icon.) " Stem inclining to ſhrubby; fruit nearly globular, ſolitary, erect." Nearly allied to the preceding. *Stem* ſmooth, a little quadrangular, branched. *Leaves* ſcattered, ſmooth, lanceolate, acuminate. *Flowers* yellowiſh white, on long peduncles; calyx ſhort, bell-ſhaped, truncate, very ſlightly toothed. *Fruit* about the ſize of a cherry, red or yellow. A native of Brazil. 4. C. *baccatum*, bird-pepper, Linn. Mant. (C. fruteſcens, β. Sp. Pl. C. fructu minimo, Brown. Jam. 176. C. minus fructu parvo, Sloane Jam. 112. Hiſt. tab. 146. *fig.* 2. β. C. minimum, Mil. n. 10?) " Stem inclining to ſhrubby, even; peduncles often in pairs; fruit very ſmall." *Stem* ſtriated, roundiſh, almoſt ſmooth; branches divaricated, zigzag. *Leaves* alternate, petioled, almoſt heart-ſhaped, acuminate, tender, ſmooth, nerved beneath. *Flowers* often in pairs, very ſmall, yellowiſh white; peduncles unequal, united at their baſe, ſtraight, pubeſcent; calyx ſhort, nearly ſmooth, with five awl-ſhaped teeth; ſegments of the corolla ſhort, obtuſe. *Fruit* globular, a little oval, ſcarcely larger than a pea, ſmooth, red or yellowiſh; peduncle ſtraight; Miller's minimum has leaves a little rounded at their ſummit, not acuminate. A native of the Indies. 5. C. *groſſum*, Linn. Mant. (C. fructu longo, per ſummum tetragono, Tour. Inſt. p. 152. C. tetragonum, Mil. n. 3?) " Stem inclining to ſhrubby; fruit erect, thickened, ſomewhat heart-ſhaped." *Stem* ſlightly pubeſcent, angular, compreſſed towards the ſummit. *Leaves* tender, alternate, lanceolate-egg-ſhaped, acute, ſcarcely longer than the petiole. *Flowers* almoſt axillary, ſolitary; peduncles ſtraight. *Fruit* bright red, globular, ſometimes a little angular, emarginate, nearly the ſize of an orange; peduncles a little curved. A native of the Indies. 6. C. *ſinenſe*, Lam. Willd. Jacq. Hort. iii. tab. 67. " Stem inclining to ſhrubby; peduncles either faſciculated or in pairs; fruit conical, very ſmall, pendulous." *Stem* ſmooth, ſtriated; branches numerous, zigzag, divaricated, angular. *Leaves* egg-ſhaped, rather large, ſharply acuminate; petioles a little pubeſcent, ſlender. *Flowers* yellowiſh white, either four or five together, or in pairs; peduncles an inch long, curved near the top; ſegments of the corolla obtuſe. *Fruit* ſmall, egg-ſhaped, terminated by the permanent piſtil, yellowiſh. A native of China. 7. C. *conicum*, Lam. Ill. (C. conoides, Mil.) " Stem inclining to ſhrubby; fruit egg-ſhaped-conical, erect." Diſtinguiſhed from ſome of the preceding chiefly by its fruit, which is about half an inch long, bright red, a little bellying at its baſe, narrowed at the ſummit into an obtuſe cone, and generally ſtanding upright on a curved peduncle. A native of the Indies. 8. C. *luteum*, Lam. Illuſt. " Stem inclining to ſhrubby, zigzag; little branches and petioles hairy; fruit egg-ſhaped, pendulous, three-celled." *Stem* nearly quadrangular, pubeſcent. *Leaves* tender, egg-ſhaped, acute, ſmooth. *Flowers* ſmall, whitiſh, ſolitary, or ſeveral together; diviſions of the corolla ſhort, acute. *Fruit* yellow, oblong, of a moderate ſize. Found in the Eaſt Indies by Sonnerat.

All the ſpecies of capſicum have the ſame general qualities, which are ſenſible in every part of the plant. The fruit is much uſed for culinary purpoſes in its native countries, and has long ſince been introduced into Europe as a poignant ingredient in ſoups and high-ſeaſoned diſhes. Its taſte is extremely acrimonious, and leaves a durable ſenſation of heat on the palate. When taken in ſmall quantities it is a grateful ſtimulant; but if uſed to exceſs, it has a painful effect, and ſeems to ſet the mouth on fire. In hot climates, where only it is indigenous, a liberal uſe of it is found to be ſalutary in ſtengthening the ſtomach, aſſiſting digeſtion, and correcting that putreſcent colliquation of the humours which thoſe climates have a tendency to produce. The ſmaller kinds of the fruit are moſt in requeſt. The fruit of capſicum baccatum in particular, gathered when ripe, dried in the ſun, and then pounded and mixed with ſalt, is kept ſtopt in bottles, and known in the Weſt Indies by the name of Cayenne butter. Pepper-pot, according to Miller, is made of the ſame ſpecies, or of that variety of it which he calls *minimum*. For this purpoſe the ripe fruit is firſt dried in the ſun, then put into an earthen or ſtone pot, with a layer of flour between each layer of fruit, and baked in an oven till it is perfectly dried. It is then cleaned from the flour, and beaten or ground to fine powder. To every ounce of this powder, a pound of wheat flour is added, and the mixture made into ſmall cakes with leaven: theſe are baked, cut into ſmall pieces, and baked again till they are as hard as biſcuit, then beaten into powder and ſifted. The reſult is the well known Cayenne pepper. Capſicum groſſum is moſt proper for pickling, the ſkin being more fleſhy and tender than in the other ſpecies. The fruit ſhould be gathered before it comes to its full ſize, ſhould be ſlit down on one ſide to get out the ſeeds, and ſoaked two or three days in ſalt and water. After it is well drained, it ſhould be covered with boiling vinegar, and cloſely ſtopped down for two months. It ſhould finally be boiled in vinegar to make it green, and will want no addition of ſpice. If the ripe fruit of any of the ſpecies be thrown into the fire, it produces a noiſome vapour which occaſions vehement ſneezing and coughing, and ſometimes vomiting. The powder taken up the noſe will cauſe violent and dangerous fits of ſneezing. Cayenne pepper, though its powerful properties have been ſo long known, has but lately been introduced as a medicine. It is now uſed both externally and internally to promote excitement, where the bodily organs are languid and torpid, and according to Dr. Woodville, as an aromatic of the moſt acrid and ſtimulating kind, may certainly be found efficacious in ſome paralytic and gouty caſes. The French authors of Demonſtrations de Botanique, ſtate it to be a powerful ſtomachic, and aſſert that ſix grains in powder mixed with honey, taken every morning, is a true ſpecific for hypochondriacal diſorders, and thoſe head-aches which proceed from a relaxed ſtomach. It has been ſucceſsfully exhibited in cynanche maligna, and in what Dr. Mackitrick calls *cachexia Africana*, which he conſiders as the moſt frequent and fatal prediſpoſition to diſeaſe among negroes. The doſe he directs is from ſix to eight grains. Bergius gave the ſeeds of capſicum with great ſucceſs in inveterate intermittents.

The annual capſicum, which is the moſt hardy, is cultivated in Spain, Portugal, and the ſouth of France, in the open air, for the ſake of its fruit, which, particularly in Languedoc and Provence, is eaten green by the peaſants at their breakfaſt, and preferred to onions or garlick. In that ſtate it is alſo pickled and uſed inſtead of capers. The ripe fruit is employed in various articles of cookery. In England the different ſpecies are cultivated chiefly for ornament, and their beauty depends in a great degree on the various and brilliant colours of the ripe fruit, which, intermixed with the green leaves and white flowers, all flouriſhing at the ſame time, makes a pleaſing appearance in the green-houſe, or the borders of the flower garden. The hardier annual ſpecies or varieties are propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring, and when the plants have ſix leaves, they ſhould be tranſplanted into another hot bed at the diſtance of four or five inches from each other, and in warm weather ſhould be allowed a good deal of freſh air. Towards the end of May, they ſhould be hardened by degrees to bear the open air, and in June may be tranſplanted into borders of rich earth. They will flower about the end of June, and will ripen their fruit in autumn. The perennial ſhrubby ſorts, after they have been brought forward in the hot-bed, as before directed for the annual ones, ſhould be planted ſingly in pots filled with rich earth, and plunged into a very moderate hot-bed, under a deep frame, where they may have room to advance. In the day-time, in warm weather, they ſhould have plenty of air, but muſt be covered with glaſſes every night, and ſhould be frequently watered. On the firſt approach of froſt, they muſt be removed into the ſtove, where they may have a temperate warmth. The fruit will continue in beauty moſt part of the winter.

CAPSIZE, *to*, in *Naval Language*, to upſet, or turn over any thing.

CAP-SQUARE, in *Artillery*, a ſtrong plate, generally of iron, which goes over the trunnion hole in each cheek of a gun-carriage, and is there curved or bent upwards into an arc, ſometimes of about 120°, but generally into a ſemicircular one nearly ſo as to form with the ſaid hole, (that is ſometimes let down into the cheek about two thirds of the diameter of the trunnion, but moſt commonly ſo as to have its centre about a quarter of an inch only below the upper ſurface of the cheek) a circle capable of receiving the ſame. It is faſtened to the priſe-plate by a hinge in the joint-bolt, by means of which, it is raiſed up or let down when wanted. The cap-ſquares, when faſtened down by means of the eye-bolts, or fore locks and keys, keep the trunnions in their holes and the guns on their carriages. There are two of them on every gun-carriage, viz. one on each cheek.

CAPSTAN, a large maſſy column ſhaped like a truncated cone, and paſſing perpendicularly through the deck of a ſhip, and turned by levers, or bars, which paſs through holes pierced in its upper extremity; ſerving, by means of a cable which winds round the barrel, to draw up burdens faſtened to the end of the cable. By the capſtan veſſels are drawn aſhore, and hoiſted up to be refitted; anchors weighed, and ſails hoiſted, cargoes diſcharged or taken in, &c.

The word is alſo written *capſtand*, *capſtern*, and even *capſtow*. It is formed from the French *cabeſtan*, which ſignifies the ſame.

The power of the capſtan is reducible to that of the AXIS *in peritrochio*.

The common moveable capſtan is exhibited in *Plate* III. *Mechanics*, *fig*. 15. A is the ſhaft, into the top of which four handſpikes, B, C, D, E, are put, for the men to turn by: this ſhaft paſſes through a collar at G, and works in a hole in the piece H; at F the rope is paſſed twice round the barrel, and to keep it from ſlipping when the barrel is turned, a man conſtantly pulls at the end or part J: this machine is prevented from moving by ſtakes, K, K, driven into the ground. Sometimes, inſtead of uſing the common barrel, AF, *fig*. 15, a double one, *fig*. 16, is uſed. A, B are the two barrels, the one A being ſmaller than the other; CC is the running rope, one end of which is faſtened to the barrel B, and the other to the barrel A; in ſuch a manner, that when the ſhaft is turned, by means of the bar, CD, one barrel will wind on the rope, and the other will wind it off; the middle of the rope goes round a pulley, D, which is hooked to the great rope E. When the machine is turned, ſo that the great barrel B winds on the rope C, and the little one A at the ſame time winds it off, it is plain that the great one takes up more rope than the other can ſupply, and it muſt therefore draw forwards the rope E; and if the two barrels are nearly of a ſize, the pulley D will advance very ſlowly, and with proportionally great power.

This capſtan might eaſily be converted into a crane, or windlaſs, for raiſing weights, merely by giving the compound barrel, AB, an horizontal poſition, and ſubſtituting a winch inſtead of the bar, CD. See CRANE. Dr. Robinſon aſcribes the invention of this kind of capſtan to an uninſtructed but ingenious country tradeſman. Encyclop. Brit. Suppl. art. Machinery, vol. xx. p. 107. It appears, however, ſays Mr. Brewſter, in his late edition of "Ferguſon's Lectures on ſelect Subjects," (vol. ii. p. 377.) to be the invention of the celebrated George Eckhardt, and likewiſe of Mr. Robert M'Kean of Philadelphia, ſon to the preſent governor of Pennſylvania.

*Fig*. 17 repreſents the capſtan uſed at the London docks for hauling the ſhips in and out of the entrance-locks. AB is a caſt-iron ſhaft, the lower end B of which works in a hole or ſocket in the bottom of a well; at A it moves in a collar in a caſt-iron plate fixed over the top of the well, and which acts as a cover thereto: by having theſe two centres at a conſiderable diſtance from each other, the capſtan works very ſteadily. At the upper end of this ſhaft is a caſt iron wheel, E, whoſe four ſpokes are hollow to receive the handſpikes by which it is turned; F is the conical barrel on which the rope is wound.

There are commonly two capſtans in a ſhip of war; the *main-capſtan* placed behind the main-maſt, ſtanding on the firſt deck, and reaching four or five feet above the ſecond: this is alſo called the *double-capſtan*, becauſe it has two drum-heads, and ſerves two decks for drawing of anchors; and becauſe its force may be doubled by applying hands on each deck. It has bars, whelps, &c. for turning and ſtopping it. See *Plate* III. *Mechanics*, *fig*. 18. The other is the *jeer-capſtan*, or *little-capſtan*: this ſtands on the ſecond deck, between the main-maſt and the mizen: its uſe is, chiefly, to heave upon the jeer-rope, or to heave upon the viol, to hold off by when the anchor is weighed; and on other occaſions where a leſs force is required, than to weigh the anchors, &c. See *fig*. 19.

The French call that an *Engliſh capſtan* where there are only half-bars uſed: and which, for that reaſon, is only half perforated: this is thicker than the others.

There is alſo a *flying capſtan*, which may be moved from place to place.

The parts of a capſtan are, the foot *d*, which is the loweſt part; the ſpindle *f*, the ſmalleſt part of which turns round in an iron ſocket, called the ſaucer; the whelps, *b*, a ſort of brackets ſet into the body of the capſtan cloſe under the bars, and reaching downwards from the lower part of the drum-head to the deck; the barrel A, the main body of the whole; the drum-head *c*, which is a broad cylindric piece of wood fixed above the barrel and whelps, in which are the holes for the bars to be put into; the bars, which are ſmall pieces of timber by which the men heave; the pins, as *e*, which are little bolts of iron, thruſt perpendicularly through the holes of the drum-head, and through a correſpondent hole in the end of the bar, made to receive them when the bars are fixed; the pawls, which are pieces of iron bolted to one end of the beams of the deck, cloſe to the body of the capſtan, but ſo as that it have liberty to turn about every way; and againſt them do the whelps of the capſtan bear; ſo as that by them the capſtan may be ſtopped from turning back. There are alſo hanging pawls, as *g*, *g*, *fig*. 18, which reach from the deck above to the drum-head immediately beneath it; and laſtly, the ſwifter, which is a rope paſſed horizontally through holes in the outer ends of the bars and drawn tight, deſigned to keep the men ſteady whilſt they work, and to afford room for a greater number to work at once.

An important improvement has lately been propoſed to the capſtan by capt. Hamilton of the royal navy, which is that of reducing the number of whelps from ſix to five, making the lower part more obtuſe, and filling it up circular by the chocks, and alſo making the upper part more perpendicular in the ſides, and open, the whelps being a portion of a circle.

Several improvements in the ſtructure of the capſtan were propoſed to the Academy of Sciences at Paris, in conſequence of the prize offered by the Academy from the year 1739 to 1741. Seven memoirs on this ſubject were publiſhed in the 5th volume of the prize pieces, forming a detail of 296 pages in 4to. The laſt improvement was ſuggeſted by Stephen-Charles de la Lande, formerly profeſſor of mathematics in the military ſchool. A report on this ſubject was made to the "Bureau de Conſultation" in 1794. The method which he propoſes for obviating the inconvenience to which the common capſtan is ſubject, when different rounds of rope are coiled about the barrel, by means of a ſcrew or ſpiral placed round the capſtan, is particularly deſcribed in the ſupplement to Montucla's "Hiſt. de Mathematiques," vol. iv. p. 585—588.

In *fig.* 20. are ſhewn Mr. Plucknett's patent additions to a capſtan, which ſave the time and trouble of ſurging the meſſenger, or rope, by which the cable is hauled in. A is a double circular inclined plane, cut in the deck under the capſtan. B, C, D, are lifters of caſt-iron, ſhewn in *fig.* 21, having a broad flat head, *a*, and a ſquare bar, *b*, with a wheel, *c*, in the bottom of it, which runs on the inclined plane, A, the ſquare part, *b*, *fig.* 2, works through the pawl-wheel, E, *fig.* 20. When the capſtan is turned, the lifters running on the inclined plane below, will move up and down; and when the rope has wound itſelf down to the bottom of the capſtan, they will puſh it up again, as ſhewn at B and C, *fig.* 20. Theſe capſtans are now in uſe in many ſhips of war, as well as merchant-men, and anſwer the purpoſe very well.

The terms belonging to the uſe of the capſtan are, *rig the capſtan*, i. e. fix the bars in their reſpective holes, thruſting in the pins in order to confine them; *heave the capſtan*, i. e. go round with it heaving on the bars; *ſurge the capſtan*; and *come up capſtan*, that is, ſlacken and let go the cable which you heave by; in a like ſenſe they alſo ſay, *launch out the capſtan*; *pawl the capſtan*, or fix the pawls to prevent it from recoiling during any interval or pauſe in heaving.

CAPSTAN-*bars*, the pieces of wood employed in heaving round the capſtan.

CAPSULA, or CAPSELLA, denotes a bag, pouch, or receptacle of divers kinds of things.

The word is a diminutive of the Latin *capſa*, literally ſignifying a little box, or caſe; particularly a bag, or ſatchel, wherein boys carry their books, &c. to ſchool.

CAPSULA, in *Chemiſtry*, is an earthen veſſel, in form of a pan; wherein things are frequently placed, that are to undergo very violent operations of the fire.

CAPSULA *Gliſſoni*, in *Anatomy*, is the anterior or right margin of the leſſer omentum, (omentum minus ſive gaſtrohepaticum) which contains ſeveral veſſels and nerves belonging to the liver and gall-bladder, connected and ſurrounded by cellular and adipoſe ſubſtance. For a further account of this part, ſee LIVER and PERITONEUM.

CAPSULA *Communis* of the vena portarum, is a covering of firm and compact cellular ſubſtance, ſurrounding the trunk of the vena potarum, and attending its ramifications throughout the liver, where it includes alſo the concomitant branches of the hepatic artery and ductus hepaticus. See LIVER.

CAPSULÆ *Atrabiliariæ*, or renales, the glandular bodies which are ſituated above the kidneys, and which are alſo deſcribed under the names of glandulæ renales, or ſupra renales, and renes ſuccenturiati. See KIDNEY.

CAPSULE, in *Botany*, (capſula, Lat. a little box) according to Linnæus is a hollow pericarp, or ſeed-veſſel, which opens ſpontaneouſly in a determinate manner, but differently in different plants, to afford a paſſage for the ripened ſeeds. Gærtner in his excellent work, "De Fructibus et Seminibus Plantarum," uſes the term in a more extenſive ſenſe, and ſtates it to be a dry conceptacle, either membranous, coriaceous, or woody, ſometimes without valves, but much more frequently opening by the means of valves, which differ from each other in number, ſituation, and figure. He divides it into four ſpecies; utricle, ſamara, follicle, and capſule in the ſtricteſt ſenſe of the word. To paſs over the evident want of logical preciſion in giving the ſame name to a whole, and to one of its parts in contradiſtinction to the reſt, the firſt two, not opening ſpontaneouſly, may be much more advantageouſly conſidered as diſtinct kinds of pericarp. See thoſe words. The follicle of Gærtner correſponds with that of Linnæus in his Syſtema Naturæ, and practical works. He had called it conceptacle in the Philoſophia Botanica, and uniformly ſeparates it from the capſule: but as it poſſeſſes all the characters expreſſed in his definition of a capſule, it would doubtleſs be more proper to treat it as a particular modification of that kind of ſeed-veſſel. See FOLLICLE.

Capſules differ from each other with reſpect to their number, the conſiſtence of their outward covering, their external form, their internal diviſion, and their mode of dehiſcence, or opening.

1. With reſpect to their number, they are either ſingle, as in lychnis, papaver, and the greateſt number of plants; or more than one in the ſame ſimple flower; either completely ſeparate from each other, as in pæonia, caltha, and ſedum; or more or leſs united, towards the bottom, as in dictamnus, nearly in their whole length as in ſtaphylæa, or ſtill more intimately as in thoſe which are called coccous, or grained. The laſt are deſcribed by Linnæus and moſt other botaniſts as conſiſting of only one capſule; but ſince each of the cocci or grains has the ſame mode of dehiſcence as occurs in pæonia, dictamnus, and others which are univerſally deemed polycapſular, it ſeems more conſonant with nature to conſider them as diſtinct. Thoſe of ceanothus americanus are ſaid by Gærtner to ſeparate ſpontaneouſly from each other in a ſtate of maturity. It muſt be acknowledged, however, that when the various capſules of this kind are compared together, they are found gradually to recede from the polycapſular character, till at length they are ſo cloſely united, that it is not eaſy to draw a preciſe line of diſtinction between them and thoſe which are ſtrictly one.

2. With reſpect to the conſiſtence of their outward covering, they are membranous, as in oxalis; coriaceous, or reſembling leather, as in æſculus; fleſhy, or ſucculent, as in pontederia; or woody, as in bankſia and cedrela.

3. With reſpect to their external form, by far the greater number of capſules are roundiſh, or egg-ſhaped; but they are ſometimes globular, as in centunculus and hottonia; cylindrical, as in dianthus; inverſely heart-ſhaped, as in veronica; angular, as in campanula; trigonous, or three-ſided, as in polemonium; four ſided, as in parnaſſia; five-ſided, as in linum; three-furrowed, as in canna; three-lobed, as in crocus; and ſo paſſing gradually to the compound capſule,

which is didymous, or two-grained, as in mercurialis; three-grained, as in euphorbia; five-grained, as in ayenia.

4. With reſpect to their internal diviſion, they conſiſt of one or more cells, (loculamenta.) When there are two or more cells, the ſubſtance by which they are ſeparated is called the diſſepiment, or partition, and the central column, the columella. See thoſe words. Some of the cells frequently become abortive as the fruit ripens, and ſometimes entirely diſappear. The only method of determining their natural number with certainty is, to make a tranſverſe ſection of the germ at an earlier period of the flower.

5. With reſpect to their mode of dehiſcence, or opening, they are one, two, three, four, five, or many-valved. A capſule is ſaid to be one-valved when it does not ſeparate into diſtinct parts. Capſules of this kind open in various ways. 1. With lateral holes; about the middle, as in moſt ſpecies of campanula; near the baſe, as in trachelium; and near the ſummit, as in papaver. 2. With a ſingle longitudinal ſlit, or chink, (rima); extending but a little below the ſummit, as in ſtaphyllæa; to the middle, as in colchicum; and from the top almoſt to the bottom, as in butomus, caltha, and many others. This ſlit is generally on the inner or concave ſide; but is found on the outer or convex one in magnolia, ægicera, and a few more. 3. With a ſhort tranſverſe ſlit on the ſummit, as in oldenlandia and hedyctis. 4. With an entire round hole at the ſummit, as in jaſione and roella; or with three, as in antirrhinum orontium. 5. With ſhort teeth, as in ceraſtium; or with deeper diviſions, but not ſo low as the middle (bifariam, &c. dehiſcentes), as in dianthus and agroſtemma. If the diviſions deſcend to the middle of the capſule, it is ſaid to be ſemi-valved; and if ſtill lower down, whether they reach the baſe or not, it is called by Linnæus two or more-valved, according to their number; two-valved, as in circæa; three-valved, as in crocus and epilobium; four-valved, as in parnaſſia; five-valved, as in droſera, &c. Gærtner calls every longitudinal diviſion a valve, although it be only a minute tooth, which ſeems preferable to the arbitrary diſtinction made by Linnæus, without any eſſential difference; but it would, as we conceive, be ſtill better to give that name only to ſuch as extend to the baſe of the capſule. They open either from the top, as in epilobium, and moſt other genera; or from the baſe, as in circæa. Gærtner aſſerts, that this difference is of no importance: but however inconſiderable it may appear in the eye of the phyſiologiſt, it ought by no means to be paſſed over in ſilence by the diſcriminating and arranging botaniſt.

Capſules are more than one-valved: 1. When they ſplit longitudinally from the ſummit, or the baſe, into two or more diviſions: 2. When they ſplit longitudinally with more than one chink, leaving the ſummit and the baſe entire, as in oxalis, xyris, and many of the orchideæ: 3. When they divide tranſverſely into two ſegments, appearing as if they had been cut round, (circumſciſſæ); about the middle, as in anagallis; near the ſummit, as in hyoſcyamus; or a little above the baſe, as in trianthema.

**CAPSULE** of the cryſtalline lens, in *Anatomy*, a production of the membrana hyaloidea, which ſurrounds the cryſtalline humour, and retains it in its ſituation. See EYE, *Anatomy of*.

**CAPSULATE PLANTS**, CAPSULATÆ *plantæ*, are ſuch as have a tetrapetalous regular flower, conſiſting of four diſtinct petala in each flower, and which bear their ſeeds in ſhort *capſulæ*: by which they are diſtinguiſhed from the *ſiliquoſæ*, which have their ſeed in long caſes, or pods.

**CAPTAIN**, in French, *capitaine*. This word, in its ordinary acceptation, ſignifies an officer who commands a company, whether it be a troop of cavalry or a company of infantry or artillery. This word had formerly a much more general meaning than it has at preſent. For it denoted the commander in chief of an army or body of troops. And in this ſenſe we ſtill make uſe of it when we ſay, that Anſlear, Annibal, Scipio, Cæſar, Turenne, Conde, Marlborough, Eugene, &c. were great captains. It was the name firſt given to the chief, head, or commander of a troop, company, or any other body of men by land or ſea.

A captain uſed to be a very conſiderable officer, and had the command of a thouſand, ſometimes of four thouſand, and ſometimes of a greater number of men.

From the time of Louis XII. to that of Henry IV. perſons moſt diſtinguiſhed for their conduct in the French armies were called captains.

In the legions of ſix thouſand men each, that were inſtituted by Francis I. every captain commanded one thouſand men, who were divided into ten centuries, commanded each by an officer who had not the name of captain, but that of centenier or centurion.

There have been inſtances in France of officers commanding corps from four to ſix thouſand men under the ſole title of captain. But theſe large bodies ſo commanded were compoſed of ſtrangers or foreigners, as Scots, Germans, Swiſs, Italians, whom gentlemen of theſe nations brought into the ſervice of the French kings, a practice that continued even under Louis XIII.

In the moſt remote times of the ancient French militia the name of captain was not given to their officers except the generals. Thoſe, who commanded under the dukes and counts were the viguers and the centeniers, during the firſt and ſecond races of their kings.

But when their ſovereigns, beſides employing the troops of their vaſſals, gave commiſſions to certain ſeigniors to raiſe companies of gens d'armes, theſe ſeigniors took the title of captain in the ſenſe annexed to it at preſent. In the buſineſs of war, this appellation indeed has always denoted a commandant or chief of troops or ſoldiers. In the old French romances that of *chevetaine*, which comes from the word chef or chief, is ſometimes made uſe of. And captain comes from *caput*, which alſo ſignifies chief.

The rank of captain, in the ordinary acceptation of the word is between that of a major and that of a lieutenant. A captain commandant is he who commands in chief a company or has the chief command of a company.

In every nation almoſt, and in every ſervice, there are captains of different denominations by the addition of other words expreſſive of the functions or duties of thoſe, on whom the compounded appellations are beſtowed.

We for inſtance make uſe of the compound term *Captain General.* By the conſtitution the king is captain general or generaliſſimo of all the forces in his united kingdoms of Great Britain and Ireland and their dependencies. The term comprehends the firſt military rank, power, and authority in the realm. In 1799 his majeſty was pleaſed to delegate this rank with the powers and authorities annexed to it to his royal highneſs the duke of York.

*Captain Lieutenant.* This compound term in our ſervice denotes the commanding officer of the colonel's troop or company in every regiment, when the colonel is either abſent or gives up the command of it to him. By an order in 1772 this officer takes rank as a full captain, and by a late regulation he ſucceeds to the firſt vacant troop or company, the price of a captain-lieutenantcy and of a company being now the ſame. The title of captain-lieutenant is ſtill made uſe of in foreign countries.

A *captain reformed* is one, who on a reduction of the army at the termination of a war and the re-eſtabliſhment of peace, loſes his company but retains his rank and pay, whether he be on duty or not.

A *captain on half pay* is one who loſes his company on a reduction of an army and retires on half pay, until ſeniority or a call for his ſervices, puts him again on duty and full pay.

A *captain en ſecond*, or ſecond captain, is one, whoſe company has been broken up, and who is joined to another to ſerve under the captain of it, during whoſe abſence, through ſickneſs or otherwiſe, he commands.

The French, by annexing others to the word captain, multiplied the compound denominations of this title to a great degree. Of theſe the following are the principal:

Capitaine general.
Capitaine lieutenant.
Capitaine en ſecond.
Capitaines des portes.
Capitaine réformé.
Capitaine conducteur general d'artillerie.
Capitaine des guides.
Capitaine des charrois.
Capitaine général des charrois de l'artillerie.
Capitaine général des vivres.
Capitaine des mulets.
Capitaine des ouvriers.
Capitaine conducteur d'artillerie.
Capitaine de mineurs.
Capitaine en pied.
Capitaine en pied ſur un vaiſſeau de guerre.
Capitaine de port.
Capitaine d'armes.
Capitaine des gardes du corps du roi.
Capitaine des cent gardes Suiſſes du roi.
Capitaine des gardes de la porte du roi.
Capitaine des gardes de la prévoté de l'hotel du roi.
Capitaine des gendarmes de la garde du roi.
Capitaine des chevaux legers de la garde du roi.
Capitaine aux gardes Françoiſes.
Capitaines en ſecond aux gardes Françoiſes.
Capitaines aux gardes Suiſſes.
Capitaines dans la gendarmerie de France.
Capitaines des gardes du corps du Monſieur frère du roi.
Capitaine des Suiſſes de la garde ordinaire du corps de Monſieur frère du roi.
Capitaines des gardes du corps de Monſeigneur le comte d'Artois frère du roi.
Capitaine des Suiſſes de la garde ordinaire de Monſeigneur le comte d'Artois frère du roi.
Capitaines commandants d'infanterie Françoiſe.
Capitaines commandants des grenadiers.
Capitaines commandants de chaſſeurs.
Capitaines a la ſuite des regiments de l'infanterie.
Capitaines a la ſuite de l'infanterie.
Capitaines a la ſuite des places.
Capitaines dans le regiment Suiſſes.
Capitaines commandants dans les regiments Allemands.
Capitaines commandants dans les regiments Irlandois.
Capitaines commandants dans les regiments Italiens.
Capitaines commandants dans les regiments Corſes.
Capitaine des grenadiers royaux.
Capitaines dans les regiments provinceaux d'artillerie.
Capitaines dans les regiments provinceaux d'etat major.
Capitaines dans les bataillons d'etat major.
Capitaines commandants dans la cavalerie.
Capitaines a la ſuite d'un regiment de cavalerie.
Capitaines a la ſuite de la cavalerie.
Capitaines de cavalerie a la ſuite des places.
Capitaines commandants de carabiniers.
Capitaines attachés au corps des carabiniers.
Capitaines commandants de chevaux legers.
Capitaines commandants de houſſards.
Capitaines a la ſuite des houſſards.
Capitaines commandants de dragons.
Capitaines de dragons a la ſuite d'un regiment.
Capitaines a la ſuite des dragons.
Captaines de dragons a la ſuite des places.
Capitaines commandants de chaſſeurs a cheval.
Capitaines dans le corps du genie.
Capitaine commandant la compagnie des cadets gentils hommes dans l'ecole militaire.

There are alſo captains of ſeveral different denominations in their corps of artillery.

Since the revolution in France ſome of theſe denominations have ceaſed, and ſome of them have been changed into others. It is not therefore our intention to give a deſcription of each of them. We will only take notice of ſome of the principal ones, and then ſpeak of the knowledge and qualifications which captains ought to poſſeſs.

The title of *captain general*, or *capitaine general*, is very ancient in France, and conferred an almoſt unlimited command on the perſon who poſſeſſed it, in the diſtrict where he commanded. But it never correſponded to that of generaliſſimo or extended to the whole French army but in the caſe of the duke of Savoy in 1635, in the time of Louis XIII. This title was revived by cardinal Mazarin in 1656 in favour of the marquis de Caſtlemont and the marquis d'Uxelles, but not with ſuch extenſive powers. For they were under the orders of the marſhal of France, and it only in fact gave the command of all lieutenant generals. It was alſo conferred on others, as Meſſieurs de Crequi, d'Humieres, de Belleſons, and de Gadagni. But it did not continue long in exiſtence. The count de Teſſé alſo had the title of captain general in Italy in 1702.

In Spain the rank of a captain general correſponds with that of a marſhal of France, who has the command of an army.

Capitaine conducteur general d'artillerie, or captain-conductor general of artillery, is the perſon who commands all the captain conductors of artillery. He has charge of the equipages and takes care that they are properly arranged and march according to the orders of the general officer of artillery, which are tranſmitted to him by the commandants of the equipages of artillery.

Capitaine general des charrois de l'artillerie, the captain general of artillery-carriages, or the captain general of the carriage of artillery. This perſon ought always to be a man of much experience as well as of a naturally good and correct underſtanding with a clear arrangement of ideas. He has the command and direction of the whole carriage of the artillery.

Capitaine des guides, or captain of the guides, is the perſon charged with the aſſembling, chooſing, forming and furniſhing of guides. He ought to underſtand different languages, and particularly that of the country, in which the army is carrying on its operations. He ſhould be active, vigilant, and intelligent, practiſed in interrogating the guides he aſſembles, expert in diſcovering which of them are beſt acquainted with ſuch or ſuch a diſtrict or tract of country, in which of them he can place moſt confidence, and who amongſt them are fitteſt to be employed as ſpies. As the army advances he diſmiſſes thoſe that are found to be uſeleſs and chooſes others. He furniſhes ſome of them on foot and ſome mounted, and for this purpoſe procures both proviſions and horſes with forage from places in the neighbourhood of the army.

He encamps near the general's quarters, and when the general mounts on horſeback to reconnoitre, he accompanies him with the moſt intelligent of the guides.

### *Of the knowledge which it is neceſſary for captains to poſſeſs.*

That an officer of this rank ought to be well acquainted with every thing neceſſary for the proper diſcharge of the duties incident to his command or ſituation either in peace or war, in garriſon or in the field, is a poſition, too obvious to be diſputed, and requires no proof.

A captain then ought to underſtand the languages moſt generally ſpoken in Europe, and particularly that of the country with which the nation he belongs to is moſt frequently at war.

He ſhould be acquainted with geography in general, and more eſpecially with that of the country or countries in which his nation is carrying on war. He ſhould know the directions and extent of the principal hills and mountains in them, the courſes of the principal rivers, their depth and fording places, how far they are navigable by ſmall veſſels, by row-boats, or by canoes, the ſituations of the principal roads, bridges, defiles, fortified places, &c. &c. in them.

He ought to be well verſed in hiſtory, particularly that of his own country; and ſhould not only be acquainted with the beſt and moſt faithful accounts or narratives of battles, both ancient and modern, but ought to examine attentively and minutely the circumſtances mentioned as attending each of them, and contributing chiefly to its failure or ſucceſs. Such a courſe of ſtudy and reflection will ſoon enable him to acquire a knowledge of military management, reſources, and expedients, greatly beyond that which his own experience might ever afford him. When placed in an unuſual or trying ſituation, he will find in it ſomething ſimilar or unlike to what he had before read or thought of, which reſemblance or diſſimilitude will immediately ſuggeſt to him expedients, and means of extricating himſelf from difficulties. It is by ſuch a judicious, careful, and attentive peruſal of hiſtory that both the ableſt generals and ſtateſmen have been formed. For no man's experience alone, without the aid of ſtudy and reflection, is ſufficient to make a man eminent in any profeſſion.

A captain ought to be well acquainted, not only with the tactics, the manœuvres, the rules, and military regulations in the ſervice of his own country, but alſo with the different branches of the art of war, and to extend his ideas and knowledge beyond the parade or a review. Regulations, in time of peace, deliver general principles; but they do not point out the happy application of them; which on ſervice depends on the judicious regulations of military maxims by circumſtances. He ought to underſtand what ſort of works are beſt adapted to any particular ſituation or poſition; their form and deſtination; the manner of tracing or conſtructing them; the materials neceſſary for reveting them; the tools and utenſils wanted for erecting them; and in ſhort every branch of knowledge requiſite for ſecuring or fortifying any given poſition properly. He ſhould likewiſe underſtand the method of increaſing the ſtrength of any poſt by means of inundations, mines, paliſades, abattis, advanced works, lines of counter-approach, &c. &c. He ſhould know well how to defend an open city, town or village, a houſe, a church, an old caſtle, a church-yard, a barn, a farm-houſe, a block-houſe, a paſs or defile, a dike, a ravine, the paſſage of a river, a ford, a wood, &c.

A captain ought alſo to make himſelf well acquainted with the buſineſs and duty of an officer commanding an advanced guard, an outpoſt, a foraging party, and every other ſort of detachment.

A captain ſhould likewiſe underſtand mathematics to at leaſt a certain extent or degree. He ſhould know the uſe of mathematical inſtruments and poſſeſs a ſufficient knowledge of geometry for ſurveying and the meaſurement of heights and diſtances. He ought alſo to underſtand algebra, as far, at leaſt, as quadratic equations.

A captain ſhould alſo know how to ſketch ground expeditiouſly, and to repreſent properly on paper the relative ſituations of hills, riſing grounds, towns, villages, ravines, highways, and other roads, as well as the relative heights nearly of the different poſitions. But a knowledge that is merely confined to this, though it be neceſſary as an elementary part of inſtruction, is of but little value, and is calculated for rendering an officer vain and conceited, and for making him ſuppoſe that he knows every thing, whilſt in reality he knows ſcarce any thing that he ought to know. He ſhould be able to determine ſpeedily whether one poſition be preferable to another, either for the reception of troops, or for the purpoſes of defence. He ſhould know how to combine caſtles, houſes, churches, church yards, dikes, fences, copſes, woods, high-ways, &c. with field-works. He ought to underſtand the beſt methods of conſtructing ſuch works, as well as the proper application of artillery to the attack and defence of field-poſitions. The doctrine of poſitions, and the combinations of attack and defence, form indeed the ſublimeſt part of the art of war.

A captain, and indeed every other officer of engineers, ought to be thoroughly acquainted with fortification, the principles of conſtruction both regular and irregular, of the attack and defence both of fortified places and field-poſitions, the theory of revetements and demi-revetements, the conſtruction of batteries, &c. &c. independently of what they ſhould know in common with other officers.

A captain, or other officer of artillery, excluſive of what he ought to know in common with the reſt of the army, ſhould be thoroughly acquainted with a variety of things peculiar to the ſervice of his own corps. He ſhould underſtand, as well as any engineer whoſoever, the conſtruction of batteries; the ſituations and ſervices to which different ſorts of ordnance are beſt adapted; in what circumſtances it is better to make uſe of ſhells and hollow ſhot, than ſolid ones, and of howitzers and mortars, than cannon; the preparing and making up of ammunition; the charges beſt ſuited to various ſervices and ſituations; the practice of firing *en ricochet;* the windage fitteſt for different ſorts and pieces of ordnance; the theory of projectiles both in vacuo and in the air; the conſtruction of guns and gun-carriages; &c. &c.

As to the phyſical qualities or qualifications of captains, they ought to poſſeſs good conſtitutions, and to be capable of enduring the continuance of fatigue, which is of the firſt conſequence on actual ſervice. Troops without theſe qualities, let their arms and dreſs be ever ſo favourable for expedition, cannot make long and rapid marches, or perform their movements with celerity, which, *cæteris paribus*, will always enſure ſucceſs to the army, that poſſeſſes it in the greateſt degree. He ſhould alſo poſſeſs courage, or perſonal bravery, as well as coolneſs or ſteadineſs in every ſituation. He ought likewiſe to enjoy diſtinct viſion to prevent confuſion and miſtakes. For though Hannibal both fought and won ſome great and important battles after he loſt the ſight of one eye, every officer is not in point of talents, contrivance, and abilities, an Hannibal.

As to his moral qualities, he ought to be honourable, juſt, temperate, free from drunkenneſs, gambling, and every other ſpecies of debauchery and diſſipation, exemplary in his conduct, conciliating in his manners, not given to quarrelling, attentive to the comfort of his ſoldiers, obedient and reſpectful to his ſuperiors, mild and humane towards his inferiors, a preſerver of ſtrict diſcipline, and at the ſame time an enemy to ſevere and ignominious puniſhments.

CAPTAIN-*baſhaw*, ſignifies the Turkiſh high-admiral. See BASHAW.

He poſſeſſes the third office in the empire, and is inveſted with the ſame power at ſea that the vizir has on ſhore. Solyman II. inſtituted this office in favour of the famous Barbaroſſa; with abſolute authority over the officers of marine and arſenal, whom he may puniſh, caſhier, or put to death, as ſoon as he is without the Dardanelles. He commands in chief in all the maritime countries, cities, caſtles, &c. and at Conſtantinople is the firſt magiſtrate of police in the villages on the ſide of the Porte, and the canal of the Black Sea. The mark of his authority is a large Indian cane, which he carries in his hand, both in the arſenal and in the army.

The captain-baſhaw enjoys two ſorts of revenues; the one fixed and the other caſual. The firſt ariſes from a capitation of the iſlands of the Archipelago, and certain governments in Natolia and Gallipoli. The latter conſiſts in the pay of the men who die during the campaign; in the fifth of all prizes made by the begs; in the profits accruing from the labour of the ſlaves, whom he hires as rowers to the grand ſignior; and in the contribution he exacts in all places where he paſſes.

CAPTAIN *reis*, or CAPIDAN *reis*, an appellation given by the Turks to the grand pilot, anſwering to pilot royal among the French.

CAPTAIN, a title given to perſons commanding ſhips of war, carrying 20 guns or upwards. The commanders of ſhips in the ſervice of the Eaſt India company are alſo ſtyled captains; and the ſame title has deſcended, very improperly, to the maſters of other veſſels.

The charge of a captain in his majeſty's navy is very comprehenſive, inaſmuch as he is not only anſwerable for any bad conduct in the military government, navigation, and equipment of the ſhip he commands, but alſo for any neglect of duty, or ill management, in his inferior officers, whoſe ſeveral charges he is appointed to ſuperintend and regulate. On his firſt receiving information of the condition and quality of the ſhip he is appointed to command, he muſt attend her conſtantly, and haſten the neceſſary preparations to fit her for ſea. So ſtrict, indeed, are the injunctions laid on him by the lord high admiral, or commiſſioners of the admiralty, that he is forbid to lie out of his ſhip, from his arrival on board till the day of his diſcharge, unleſs by particular leave from the admiralty, or his commander in chief. He is enjoined to ſhew a laudable example of honour and virtue to the officers and men, and to diſcountenance all diſſolute, immoral, and diſorderly practices, and ſuch as are contrary to the rules of diſcipline and ſubordination, as well as to correct thoſe who are guilty of ſuch offences as are puniſhable according to the uſage of the ſea. He is ordered particularly to ſurvey all military ſtores which are ſent on board, and to return whatever is deemed unfit for ſervice. His diligence and application are required to procure his complement of men, obſerving carefully to enter only ſuch as are fit for the neceſſary duty, that the government may not be put to improper expence. When his ſhip is fully manned, he is expected to keep the eſtabliſhed number of men complete, and ſuperintend the muſter himſelf, if there is no clerk of the check at the port. When his ſhip is employed on a cruiſing ſtation, he is expected to keep the ſea the whole length of time previouſly appointed; but if he is compelled, by ſome unexpected accident, to return to port ſooner than the limited time, he ought to be very cautious in the choice of a good ſituation for anchoring, ordering the maſter, or other careful officer, to ſound and diſcover the depths of water and dangers of the coaſt. Previous to any poſſibility of an engagement with the enemy, he is to quarter the officers and men to the neceſſary ſtations, according to their office and abilities, and to exerciſe them in the management of the artillery, that they may be more expert in the time of battle. His ſtation, during the time of an engagement, is on the quarter-deck; at which time he is expected to take all opportunities of annoying his enemy, and improving every advantage over him, to exhibit an example of courage and fortitude to his officers and crew, and to place his ſhip oppoſite to his adverſary, in ſuch a ſituation, as that every cannon ſhall do effectual execution. At the time of his arrival in port, after his return from abroad, he is to aſſemble his officers, draw up a detail of the obſervations that have been made during the voyage, of the qualities of the ſhip, as to her trim, ballaſt, ſtowage, manner of ſailing, for the information and direction of thoſe who may ſucceed him in the command; and this account is to be ſigned by himſelf and officers, and to be returned to the reſident commiſſioner of the navy at the port where the ſhip is diſcharged, and to tranſmit a duplicate of the ſame to the navy board.

The pay of captains in the royal navy was formerly very ſmall; this defect was, however, made up by indulging them in many privileges not now allowed; as plundering of prizes, taking convoy-monies, and even carrying merchant goods, plate, &c. King James II. taking this laſt privilege away, in lieu thereof granted them an annual allowance of table-monies, almoſt equal to their whole former pay. But this not taking place, by reaſon of the abdication, king William III. in 1693, ordered the pay of captains to be doubled; but the fund for this failing at the peace of Ryſwick, a new eſtabliſhment was made in 1700, whereby nearly one-third was retrenched from the ſea-pay, and that of a firſt rate was fixed at 1l. of a ſecond rate at 16s. and a third rate at 13s. 6d. of a fourth rate at 10s. of a fifth rate at 8s. and of a ſixth rate at 6s. per day.

Captains of poſt ſhips, after three years from the date of their firſt commiſſion, rank as colonels in the army.

Admirals' ſhips, and thoſe of the firſt rate, in the French navy, have two captains, two lieutenants, and two enſigns.

CAPTAIN, or more properly, *maſter*, of a merchant ſhip, is the perſon who has the direction of the ſhip, crew, and lading, &c. The proprietor of the veſſel appoints the maſter, and the maſter engages his mate, crew, and pilots, &c.; though, when the proprietor and maſter reſide in or near the ſame place, they generally act in concert together. In the Mediterranean the maſter is called the *patron*, or *patroon*.

CAPTAIN, a title in the royal navy, given to thoſe perſons who have the charge or command of a gun, of the tops, &c.

CAPTAINS *of port*, in the French *Marine Affairs*, officers eſtabliſhed in ſome conſiderable ſea-ports where there are arſenals. To them belong the command of the guard of the place, the watching of the ſea, and the care and cuſtody of the veſſels brought into port.

There are ſuch captains at Toulon, Rochfort, Breſt, Havre, Dunkirk, and Port Lewis. They are to take care of mooring the king's ſhips, and oblige all to give the due ſalutes.

CAPTAIN's *Clerk*, a perſon employed by the captain to keep his accounts, &c. His pay is the ſame as that of a midſhipman. The captain is anſwerable for the faults of his clerk; nor can he receive his wages without proper certificates, and muſt make good all damages ſuſtained by his neglect or irregularity. By a recent regulation, no perſon can be a purſer unleſs he has ſerved two years as captain's clerk.

CAPTAINRY, *capitainerie*, in the French *Law*, denotes the government or command of a royal palace, and the lands dependent thereon.

The name is alſo applied to the office of captains of chaces or woods: ſuch are the capitainries of Fontainbleau, the wood of Boulogne, &c.

CAPTIAUX, in *Geography*, a town of France, in the department of the Gironde, and chief place of a canton in the diſtrict of Bazas; 3 leagues S. of Bazas. The place contains 1152, and the canton 3015, inhabitants; the territory comprehends 362½ kiliometres and 6 communes.

CAPTION, in *Law*, is that part of a legal inſtrument, as a "commiſſion," "indictment," &c. which ſhews where, when, and by what authority, it is taken, found, or executed. Thus, when a commiſſion is executed, the commiſſioners ſubſcribe their names to a certificate, declaring when and where the commiſſion was executed. The caption uſually commences with theſe words, *Virtute iſtius commiſſionis nos*, &c. or, *Executio iſtius commiſſionis patet in quadam ſchedula annexata*, &c. or *Capt. & cogn. die*, &c. or *Capt. fuit hæc reſponſ.* Captions of this kind relate chiefly to three ſorts of buſineſs; to commiſſions to take fines of lands, to take anſwers in chancery, and depoſitions of witneſſes.

Theſe captions, and the executions of the commiſſions, muſt now be in Engliſh, by 4 Geo. II. cap. 26.

The word *Caption*, is alſo uſed, vulgarly, for an arreſt.

Caption, in *Scots Law*, a writ iſſuing under his majeſty's ſignet, in his majeſty's name, obtained at the inſtance of a creditor in a civil debt, commanding meſſengers at arms, and other officers of the law, to apprehend and impriſon the perſon of the debtor until he pay the debt.—Alſo, the name of a writ iſſued by the court of ſeſſion againſt the agents of the court, to return papers belonging to proceſſes or law-ſuits, or otherwiſe to go to priſon.

CAPTIVE, a ſlave, or perſon taken by the enemy in war, or by a pirate or corſair. See Slave.

Captives, *captivi*, among the Romans, differed from *dedititii*, as the former were taken by force, whereas the latter ſurrendered themſelves.

By the *Lex Cornelia*, a Roman citizen taken captive, in caſe he returned, was reputed as having never been taken; if he died in captivity, he was reputed for dead the moment he was taken: in the former caſe he recovered all his right, and even the dominion over his children; in the latter his ſon became free from the time of his father's detention. Juſtin. Inſt. lib. i. tit. xii. § 5.

Formerly captives in war became the ſlaves of thoſe who took them; and though ſlavery, ſuch as obtained among the ancients, be now aboliſhed, ſome ſhadow of it ſtill ſubſiſts in reſpect of priſoners of war, who are reputed the property of their captors, and have no right to liberty, but by conceſſion from them, or till their ranſom is paid. Negro ſervants likewiſe, who are purchaſed when captives, continue in ſome degree the property of the maſters who buy them; though the property (if it indeed continues) conſiſt rather in the perpetual ſervice than in the body or perſon of the captive. Blackſt. Com. vol. ii. p. 402. See Negro and Slave.

The Romans uſed their captives with great ſeverity; their necks were expoſed to the ſoldiers to be trampled on, and their perſons afterwards ſold by public auction. Captives were frequently burnt in the funeral piles of the ancient warriors, as a ſacrifice to the infernal gods. See Burial. Thoſe of royal or noble blood had their heads ſhaven, and their hair ſent to Rome, to ſerve as decorations in female toys, &c. They were led in triumph loaden with chains through Rome, in the emperor's train, at leaſt as far as the foot of the Capitoline mount, for they were not permitted to aſcend the ſacred hill, but carried thence to priſon. Thoſe of the prime quality were honoured with golden chains on their hands as well as feet, and golden collars on their necks. If they made their eſcape, or killed themſelves to avoid the ignominy of being led in triumph, their images or effigies were frequently carried in their place."

CAPTIVITY is uſed in *Scripture* to denote the puniſhment inflicted by Providence on the Jews, for their idolatry and wickedneſs.

Their firſt captivity in Egypt, from which they were reſcued by Moſes, ſhould be conſidered rather as the reſult of providential diſpenſation than as a penal evil. See Exodus. The ſubſequent captivities of the Jewiſh people may be regarded as chaſtiſements of Providence for their relapſe into idolatry, and as means of reclaiming them to the acknowledgment and worſhip of the true God. The ſcripture hiſtory informs us of ſix captivities, which took place during the government by Judges. The *firſt* was that under Chuſhan-Riſhathaim, king of Meſopotamia, and continued eight years, from the year B.C. 1391 to 1383, when they were delivered by Othniel, the ſon of Kenaz, Caleb's younger brother. The *ſecond* was that under Eglon, king of Moab, and laſted 18 years, viz. from the year B.C. 1343 to 1325. From this they were reſcued by Ehud; and the eaſtern part of the country of Iſrael, after having been emancipated from the yoke of Moab, had reſt 80 years. However, in the mean while, the Philiſtines invaded the weſtern parts, and were repulſed by Shamgar. (Judg. iii. 31.) This is reckoned the *third* captivity. The *fourth* was that of the northern tribes by Jabin, king of Hazor, from which they were delivered by Deborah and Barak, in the year B.C. 1285; after which period the northern part of the territory of Iſrael had reſt 40 years. (Judg. iv. 2. v. 31.). The *fifth* captivity, comprehending north and eaſt Iſrael, was that under the Midianites, which laſted ſeven years, from the year B.C. 1245 to 1238; and from this the inſtrument of their deliverance was Gideon. (Judg. vi. 1, &c.) Their *ſixth* captivity was that under the Ammonites and Philiſtines. While Jair was judge over north and eaſt Iſrael (B.C. 1173), theſe diſtricts were in bondage to the Ammonites 18 years (Judg. x. 8.); and at the ſame time with Jair, Eli began to judge ſouth and weſt Iſrael 40 years, (1 Sam. iv. 18.), during which whole period that part of Iſrael was oppreſſed by the Philiſtines. (Judg. xiii. 1.). In the firſt of theſe 40 years of Eli, which was alſo the firſt year of Jair, Samſon was probably born; and he lived 40 years, judging weſt Iſrael (while Eli alſo was judge there, and while that part of the country was under the Philiſtines) 20 years. (Judg. xv. 20.). North and eaſt Iſrael were delivered from the Ammonites, after an oppreſſion of 22, or 21 complete years, in the year B.C. 1152. (Judg. x. 3.). The oppreſſion of the Philiſtines continued during the judicatures of Ibzan, Elon, Abdon, Eli, Samſon, and Samuel. Ibzan preſided over north and eaſt Iſrael five or ſix complete years, from the year B.C. 1147 to 1140 (Judg. xii. 7.), when he was ſucceeded by Elon. About the fifth year of Elon (B.C. 1155), Samuel was publicly known to be a prophet. (1 Sam. iii. 20. iv. 1.). About the ſeventh of Elon (B.C. 1133), Samſon pulled down the temple (Judg. xvi. 30.), and deſtroyed a great number of the Philiſtines. Uſher thinks that this calamity might encourage the ſouth and weſt Iſraelites to give them battle. (1 Sam. iv. 1.). Elon was ſucceeded in the judicature of north and eaſt Iſrael by Abdon, B. C. 1130; and Abdon by Samuel, B. C. 1122, who was now judge over north and eaſt Iſrael, as he had been before over ſouth and weſt Iſrael. (1 Sam. vii. 15, 16, 17.)

However, the moſt ſignal captivities which theſe people experienced, were thoſe of Iſrael and Judah, under the ſovereigns of theſe kingdoms, after they were ſeparated B. C. 975, denominated the *Aſſyrian* and *Babyloniſh*.

The *Aſſyrian* captivity, which comprehended that of the ten tribes, commenced in the reign of Pekah, king of Iſrael, B. C. 740, when Tiglath-Pilezer, king of Aſſyria, took ſeveral cities of Iſrael, and carried away captives, principally from the tribes of Reuben, Gad, and the half tribe of Manaſſeh. (1 Chron. v. 26. 2 Kings, xv. 29.). In the ſixth year of Hezekiah, king of Judah, and ninth year of Hoſhea, king of Iſrael, B. C. 721, Shalmaneſer, king of Aſſyria, took and deſtroyed Samaria, after a ſiege of three years, tranſplanted thoſe of the ten tribes, that had been ſpared by his father, Tiglath-Pilezer, to Nineveh, and provinces beyond the Euphrates, and thus diſperſed them among the Gentiles. (2 Kings, xviii. 10, 11.). Moreover, in the 22d year of Manaſſeh, king of Judah, B. C. 676, Eſarhaddon or Aſſaradinus, king of Aſſyria and Babylon, made the laſt deportation of the Iſraelites, and planted others in their ſtead; and in the ſame expedition, probably, took Manaſſeh captive, and carried him to Babylon. (2 Kings, xvii. 24. 2 Chron. xxxiii. 11. Ezra, iv. 2.). The Aſſyrian captivity of the ten tribes of Iſrael, ſometimes denominated Ephraim, from the chief of them, was predicted by Iſaiah (ſee chap. vii. 8.) in the firſt year of Ahaz, king of Judah, B. C. 741. "Within threeſcore and five years," ſays the prophet, "ſhall Ephraim be broken, that it be not a people." This period has very much puzzled the ſcripture critics. If this prophecy was delivered in the firſt year of Ahaz, and Shalmaneſer took Samaria, and carried away Iſrael (Ephraim) into Aſſyria, in the ſixth year of Hezekiah, we ſhall only have an interval of 21, inſtead of 65 years. For the ſolution of this difficulty, the learned Vitringa ſuppoſes that the text is corrupted, and that inſtead of 60 (שׁשׁים) and 5, it was originally written 16 (שׁשׁי) and 5. This conjecture would appear much more probable, if it could be proved, that it had ever been uſual to write the numbers or dates of years partly in words at length, and partly in numeral letters. But it is not neceſſary to recur to this expedient. For if we compute, from the firſt of Ahaz, 65 years in the reigns of Ahaz, Hezekiah, and Manaſſeh, they will terminate about the 22d year of Manaſſeh, when the captivity of the Iſraelites was completed by Eſarhaddon.

It has been generally ſuppoſed, that the greater part of the ten tribes was loſt in this captivity, which put a period to the kingdom of Iſrael. It is certain, that immediately upon their deportation, they were placed in Aſſyria and Media; and if they ſubſiſted any where, it is natural to imagine that they might be found there in the greateſt number. But authors have generally ſought for them elſewhere. Accordingly, the viſionary writer of the ſecond book of Eſdras (xiii. 40, &c.) affirms, that they adopted a reſolution of retiring from the Gentiles, and of emigrating into a country which had never been inhabited; that the Euphrates was miraculouſly divided for their paſſage; and that after purſuing their journey for a year and a half, they arrived at the country, Arſaxeth; a country the ſituation of which has not been duly aſcertained. See AFGHANS. Benjamin Tudela, a Jew of the 12th century, has aſſigned them a large and ſpacious country, with fine cities, in a ſituation that is altogether unknown. Eldad, another Jew, of the 13th century, has placed them in Ethiopia, and hath made the Saracens and 25 kingdoms tributary to them. Another Jewiſh writer, Peritſol of Ferrara, who lived in the 16th century, has allotted to them kingdoms in a country called Perricha, incloſed by unknown mountains, and bounded by Aſſyria, and likewiſe in the deſerts of Arabia, and even in the Eaſt Indies. Manaſſeh, a famous rabbi of the 17th century, and others, have aſſerted, that they paſſed into Tartary, and expelled the Scythians; and others again from Tartary have conveyed them to America. Moſt of theſe accounts are unfounded conjectures, and ſome of them are manifeſt forgeries of the Jews to aggrandiſe their own nation. However, ſome reſpectable modern writers imagine, that they have found exiſting traces of them in the northern parts of India, particularly among the AFGHANS. The difficulty of aſcertaining the habitations of the ten tribes, has induced others, among whom we may reckon Calmet, to maintain, that they returned into their own country, with the other two tribes, after the Babyloniſh captivity. To this purpoſe it is alleged, that their return was predicted. See Hoſea, xi. 11. Amos, ix. 14. Obadiah, 18. 20. Iſaiah, xi. 13, 14. Ezekiel, xxxvii. 16. Jerem. xxxi. 7, 8, 9. 16, 17. 20. xvi. 15. xlix. 2. &c. Zech. ix. 13. x. 6. 10. Micah, ii. 12. Beſides, in the hiſtorical books of ſcripture, waving any reference to the apocryphal book of Tobit, Iſraelites, as well as thoſe of Judah and Benjamin, are reported to have returned from the captivity. When Ezra numbered thoſe that were returned from the captivity, he only inquired whether they were of the race of Iſrael; and at the firſt paſſover, then celebrated in the temple, there was a ſacrifice of "12 he-goats for the whole houſe of Iſrael, according to the number of the tribes." Ezra, vi. 16, 17. viii. 35. Under the Maccabees, and in the time of our Saviour, Paleſtine was peopled with Iſraelites of all the tribes, without diſcrimination. However, as the decree of Cyrus extended to "all the people of God" (Ezra, i. 3.), and that of Artaxerxes to "all the people of Iſrael" (vii. 13), there can be no doubt that many of the Iſraelites availed themſelves of theſe decrees, and returned with Zerubbabel and Ezra to their own cities; nevertheleſs, the main body of the ten tribes remained behind. Accordingly, Ezra, upon whoſe authority we may depend, informs us, that there "roſe up the chief of the fathers of Judah and Benjamin" (ch. i. 5.), and he calls the Samaritans "the adverſaries of Judah and Benjamin" (ch. iv. 1.); and hence we may infer, that theſe two tribes were the principals, and that the others were only acceſſories. And if they did not return at this time, they cannot be ſuppoſed to have returned, at leaſt in a conſiderable body, at any future time; for hiſtory informs us of no ſuch adventure, nor do we know either the time or occaſion of their return, or who were their conductors in this expedition. Joſephus, who ſaw his country for ſeveral years in as flouriſhing a condition as any time ſince the captivity, affirms (Antiq. lib. xi. cap. 5. §. 2.), that Ezra ſent a copy of the decree of Artaxerxes to all of the ſame nation throughout Media, where the ten tribes lived in captivity, and many of them came with their effects to Babylon, deſiring to return to Jeruſalem; but the main body of the Iſraelites abode in that region; and therefore it hath happened, ſays this Jewiſh hiſtorian, that there are two tribes in Aſia and Europe, living in ſubjection to the Romans; but the ten tribes are beyond the Euphrates to this time; and he then adds, with the vanity of a Jew, ſpeaking of his countrymen, that they were ſo many myriads, that they could not be numbered. Others, who have found no ſufficient authority for admitting that the ten tribes of Iſrael were reſtored in the ſame manner as the two tribes of Judah and Benjamin, have therefore aſſerted (ſee Prideaux's Conn. pt. I. b. I.) that the ten tribes of Iſrael, which had ſeparated from the houſe of David, were brought to a full and utter deſtruction, and never after recovered themſelves again. For thoſe who were thus carried away (excepting only ſome few, who joining themſelves to the Jews in the land of their captivity returned with them) ſoon falling into the uſages and idolatry of the nations among whom they were planted, to which, indeed, they were too much addicted while they remained in their own land, after a while became wholly abſorbed in them; and thence utterly loſing their name, their language, and their memorial, were never after any more mentioned. To this ſtatement, however, it has been very juſtly objected, that if the whole race of Iſrael became thus extinct, we ſhall in vain expect the fulfilment of the numerous prophecies, that promiſe the future converſion and reſtoration of Iſrael as well as of Judah. The truth, ſays biſhop Newton (Diſſertations on the Prophecies, apud Works, vol. vii. p. 195, &c. ed. 8vo.), ſeems to lie between theſe two opinions. "Neither did they all return to Jeruſalem, neither did all, who remained behind, comply with the idolatry of the Gentiles, among whom they lived. But whether they remained, or whether they returned, this prophecy of Iſaiah (ch. vii. 8.) was ſtill fulfilled; the kingdom, the commonwealth, the ſtate of Iſrael was utterly broken; they no longer ſubſiſted as a diſtinct people from Judah; they no longer maintained a ſeparate religion; they joined themſelves to the Jews from whom they had been unhappily divided; they loſt the name of Iſrael as a name of diſtinction, and were thenceforth all in common called Jews. It appears from the book of Eſther, that there were great numbers of Jews in all the 127 provinces of the kingdom of Ahaſuerus, or Artaxerxes Longimanus, king of Perſia, and they could not all be the remains of the two tribes of Judah and Benjamin, who had refuſed to return to Jeruſalem with their brethren; they muſt, many of them, have been the deſcendants of the ten tribes whom the kings of Aſſyria had carried away captive; but yet they are all ſpoken of as one and the ſame people, and all without diſtinction are denominated Jews." See alſo Acts, ii. 9. ch. xxvi. 7. James, i. 1. Without doubt, ſeveral perſons of all the ten tribes are now in being, though we cannot diſtinguiſh them from the other Jews, with whom they are confounded and intermixed.

It appears, therefore, to be a fact, that the ten tribes of Iſrael were in a manner loſt in their captivity, while the two tribes of Benjamin and Judah were reſtored and preſerved ſeveral ages afterwards. Should an inquiry be made into the reaſon of this difference, it may be alleged, that the ten tribes had totally revolted from God to the worſhip of the golden calves in Dan and Bethel; and for this, and their other idolatry and wickedneſs, they were ſuffered to remain in the land of their captivity.

The *Babyloniſh* captivity comprehended that of the kingdom of Judah, or of the two tribes of Judah and Benjamin, who adhered to the houſe of David, and laſted 70 years.

The mode of eſtimating its duration has been attended with ſome difficulty, on account of the different captivities of the Jewiſh nation, which occurred about the ſame period. Of theſe there have been reckoned five. The *firſt* happened in the fourth year of Jehoiakim, B. C. 606, when Nebuchadnezzar, admitted to partnerſhip with his father in the kingdom of Babylon, marched to Carchemiſh, with a great army, to recover from the king of Egypt all that he had lately conquered in Syria and Phœnicia. In the courſe of this expedition, he invaded and ravaged Judæa, beſieged and took Jeruſalem, made Jehoiakim his ſubject and tributary, tranſported the fineſt children of the royal family and of the nobility, and among the reſt Daniel and his companions, to Babylon, to be bred up there for eunuchs and ſlaves in his palace, and alſo carried away the veſſels of the houſe of the Lord, and put them in the temple of his god at Babylon. (Dan. i. 1, 6.) The *ſecond* captivity happened in the ſeventh year of Jehoiakim, B. C. 603, when Nebuchadnezzar, immediately after his father's death, returned to Judæa, made captives of many Jews, and bound their king in order to carry him to Babylon; though he reſtored him afterwards to his kingdom, having received the ſtrongeſt aſſurances of ſubjection and allegiance. Notwithſtanding theſe profeſſions of obedience, Jehoiakim again rebelled, in the 11th year of his reign, B. C. 599. Nebuchadnezzar, hearing of this revolt, came againſt him with a prodigious army, and threatened all Judæa with deſtruction. Intimidated by this menace, Jehoiakim ſurrendered himſelf into the hands of his enemy, who ſlew him, together with many of the nobles, in Jeruſalem, and placed his ſon upon the throne. (2 Chron. xxxvi. 6.) Afterwards repenting of what he had done, and fearing leſt Jehoiachin ſhould embrace ſome future occaſion of revenging his father's death, Nebuchadnezzar returned within three months, carried that unfortunate prince into captivity, and appointed Zedekiah to reign in his ſtead. (2 Chron. xxxvi. 9. 2 Kings, xxiv. 10, &c.) This may be reckoned the *third* captivity of the Jews by the king of Babylon. On this occaſion Mordecai and Ezekiel were among the captives. (Eſth. ii. 5, 6. Ezek. i. 1, 2.) The *fourth* was in the 11th year of Zedekiah, 588 B. C., when the whole land was made deſolate, when the city and temple of Jeruſalem were deſtroyed, (the city being taken and burnt after a ſiege of 18 months, in the year B. C. 587, and the temple burnt in the year B. C. 586.) and when Zedekiah, king of Judah, was bound with fetters of braſs, and carried priſoner to Babylon, where he died. (2 Kings, xxxv. 2, 9. 2 Chron. xxxvi. 10. Ezek. xii. 13.) The *fifth* captivity occurred in the 21ſt year of Nebuchadnezzar's reign, B. C. 584, when that monarch ſent Nabuzaradan, captain of his guard, to revenge the death of Gedaliah, governor of Judæa. Nabuzaradan deſolated the land, and carried to Babylon the wretched remains of that miſerable nation.

To each of theſe captivities the date of the period of 70 years has been referred. But the firſt of them, in the fourth year of Jehoiakim, B. C. 606, ſeems to be the moſt accurate commencement of this period, and alſo the moſt agreeable to Scripture. The interval, extending thence to the ſecond year of Cyrus, B. C. 536, when the Jews were permitted to return to their own land, amounts to 70 years; for Cyrus conquered Babylon towards the cloſe of the year, B. C. 538; ſo that the year following, viz. 537, was the firſt year of his reign, and 536 the ſecond, and the 71ſt from the fourth year of Jehoiakim. The date of the Babyloniſh captivity may be aſcertained, ſays Playfair, (Chronol. p. 45.) by the following facts. Nebuchadnezzar became maſter of Tyre in the 34th year of his reign, the 26th of Jehoiakim's captivity, and 573 B. C. (572 B. C. Blair) as we learn from the Tyrian annals. (Joſeph. cont. App. l. i. §. 21.) Cyrus took Babylon in the 14th year of Hiram, and 36th after it had been taken by Nebuchadnezzar, i. e. in the end of the year 538 B. C. In this inſtance, therefore, the Tyrian records confirm the ſacred chronology.

The captivity and reſtoration of the two tribes were foretold; and moreover the preciſe time of both events was alſo prefixed and determined by the prophet Jeremiah, ch. xxv. 11. xxix. 10. This prophecy was firſt delivered (Jer. xxv. 1.) in the fourth year of Jehoiakim; and this ſame year Nebuchadnezzar began to put it in execution. If the commencement of the 70 years' captivity be fixed at the time when Jeruſalem was burnt and deſtroyed, their concluſion will fall about the time when Darius, the ſon of Hyſtaſpes, iſſued his decree for rebuilding the temple, after the work had been ſuſpended, which was in the fourth year of his reign and B. C. 518. Or again if we fix their commencement at the time when Nabuzeradan carried away the laſt remnant of the people, and completed the deſolation of the land, their concluſion will fall about the time when the temple was finiſhed and dedicated, and the firſt paſſover ſolemniſed in it, which was the ſeventh year of Darius and the 515th B. C. Hence Dr. Prideaux obſerves (Conn. part 1. book 3.), "that taking it which way you will, and at what ſtage you pleaſe, the prophecy of Jeremiah will be fully and exactly accompliſhed concerning this matter." Or, it may be ſaid to have been accompliſhed, as biſhop Newton obſerves (vol. vii. p. 187.), at three different times, and in three different manners, and therefore poſſibly all might have been intended, though the firſt was without doubt the principal object of the prophecy. The prophets Iſaiah (xliv. 28.) and Ezekiel (xxxvi. 10, &c.) have previouſly drawn lively pictures of the happy days that ſhould ſucceed the captivity, which were actually realized; for the people returning to their own country, enjoyed the bleſſings of liberty and affluence. The people were multiplied, their cities were inhabited, and their waſtes were cultivated. Whilſt the 10 tribes were diſperſed and loſt, thoſe of Benjamin and Judah, or the Jews, were reſtored, not ſo much for their own ſakes, as for the ſake of the promiſes made unto the fathers, the promiſe to Judah that the Meſſiah ſhould ſpring from his tribe, and the promiſe made to David that the Meſſiah ſhould be born of his family. It was therefore neceſſary for the tribe of Judah, and the families of that tribe, to be kept diſtinct until the coming of the Meſſiah. But ſince theſe ends have been fully anſwered, the tribes of Judah and Benjamin are as much confounded as any of the reſt; all diſtinction of families and genealogies is loſt among them, and the Jews themſelves acknowledge as much, when they ſay, that when the Meſſiah ſhall come, it will be part of his office "to ſort their families, reſtore their genealogies, and ſet aſide ſtrangers."

The captivity, conſidered as a diſpenſation of providence, will appear to have been highly neceſſary and proper, if we reflect, that the lenity of God was manifeſt in bringing this terrible overthrow on the Jews ſo gradually, after a ſucceſſion of judgments from leſs to greater for the ſpace of 22 years, which ſhould have been a warning to them, and by experience have convinced them, that the threatenings denounced by the prophets would certainly be executed:—that it was a juſt puniſhment of their ſins, particularly of their idolatry:—that it was the moſt effectual means to produce their reformation, the great end propoſed by divine wiſdom; and indeed it had this effect, in a very conſiderable degree, for they never more fell into idolatry, but retain the greateſt abhorrence of it even to this day:—that they had ſo far neglected the law of God, written by Moſes, as the rule of their conduct in all affairs civil and religious, and the ground of their happineſs, that at one time it was almoſt unknown and loſt among them (2 Kings, xxii. 8, 12.):—and that this diſpenſation was alſo calculated to produce beneficial effects among the nations, whither they were carried into captivity. The Jews, notwithſtanding their depravity in their own country, during the captivity of 70 years, muſt have been a burning and ſhining light, all over the countries of the eaſt.

Beſides the captivities already enumerated, there happened another conſiderable captivity and diſperſion of the Jews in the time of Ptolemy, the ſon of Lagus, uſually called Soter, about the year B. C. 319; who invaded Judæa, beſieged and took Jeruſalem, and carried above 100,000 of the inhabitants captives into Egypt, planting them in Alexandria and adjacent places. Ptolemy, though at firſt he treated Jeruſalem and Judæa with great ſeverity, conſidering afterwards the ſteadineſs with which they had perſiſted in the fidelity they had ſworn to their governors, on this and a variety of other occaſions, and convinced that this quality rendered them worthy of his confidence, choſe 30,000 of the moſt diſtinguiſhed among them and of ſuch as were moſt capable of ſerving him, and appointed them to guard the moſt important places in his dominions. Many of the Jews followed their captive brethren of their own accord, partly allured by the favour of the king, who gave them equal privileges with thoſe of Alexandria, and partly by the fertility of the country, ſo that this colony, from which ſprung the HELLENISTS, became very conſiderable. The laſt captivity of the Jews was that which happened in conſequence of the deſtruction of their city and temple under Titus about 40 years after our Saviour's aſcenſion. See JERUSALEM.

**CAPTIVITY**, *princes of the*, are heads or chiefs of the Jewiſh nation, appointed for the adminiſtration of juſtice among them, during their captivity both in the eaſt and weſt, ſince the deſtruction of their temple by the Romans. The prince of the captivity in the eaſt, is ſaid to have had the government of the Jews who dwelt in Babylon, Chaldæa, Aſſyria, and Perſia. The prince of the captivity in the weſt, had the direction of thoſe who lived in Judæa, Egypt, Italy, and other parts of the Roman empire. The Jews make a great difference between the patriarchs of Judæa, and the princes of the captivity at Babylon. The latter were called "rabbans," and were ſuppoſed to have deſcended from David, in a direct line by the males; the former or patriarchs, called "rabban," only deſcended from David by the females. The patriarch, who reſided in Judæa, made Tiberias the place of his cuſtomary abode, and aſſumed the title of "Roſchabboth," i. e. the head of the fathers or patriarchs. He preſided in aſſemblies, decided in caſes of conſcience, levied taxes for defraying the charges of his viſits, and diſpatched ſubordinate officers through the provinces to execute his orders. As to the princes of the captivity of Babylon, or the eaſt, their origin and ſucceſſion are unknown; but it does not appear that they ſprung up till about the end of the ſecond century. While the temple ſubſiſted, the eaſtern Jews, as well as weſtern, continued ſubject to the high prieſt. The firſt of theſe princes is ſaid to have been Huna, at the cloſe of the ſecond century; and from Huna to the perfection of the talmud, i. e. 300 years, they ſcarcely produce three. Calmet. See ÆCHMALOTARCHA.

**CAPTURE**, a prize, or prey; particularly that of a ſhip taken at ſea. Captures made at ſea were formerly held to be the property of the captors after a poſſeſſion of twenty-four hours; but the modern authorities require, that before the property can be changed, the goods muſt have been brought into port, and have continued a night *intra præſidia*, in a place of ſafe cuſtody, ſo that all hope of recovering them was loſt. Blackſt. Com. vol. ii. p. 401. See PRIZE and PRIVATEER.

**CAPTURE** alſo denotes an arreſt, or ſeizure of a criminal, debtor, &c. at land.

**CAPTURE**, *de Deſerteurs*. There exiſted under the old government of France an order, by which every intendant of a province or commiſſary of war was authoriſed to pay 100 livres to any perſon or perſons, who ſhould apprehend or ſecure a deſerter, and 300 livres for every man, that could be proved to have enticed a ſoldier away from either the regular army or the militia.

CAPUA, in *Ancient Geography*, a city of Italy, the metropolis of Campania, derives its name, according to Strabo, from *caput*, head. It was ſituated at ſome diſtance to the north of Neapolis, near the mountains; and it was the chief and moſt important city of Magna Græcia. According to Florus, it was one of the three moſt celebrated cities known to the ancients, who placed it next to Rome and Carthage.

"Altera dicta olim Carthago, atque altera Roma,
Nunc proſtrata jacet, proprioque ſepulta ſepulchro."

It is ſaid to have been founded by the Tyrrhenians, who had extended their power into Magna Græcia, about 48 years before the foundation of Rome, or 800 years before the Chriſtian æra. When the Samnites made themſelves maſters of the country, Capua fell into their hands, and Livy ſeeks the etymology of its name in that of their chief, called "Capys." The aſtoniſhing fertility of the adjacent country, and a lucrative commerce, poured, at an early period, immenſe wealth upon its inhabitants, ſo that it became one of the moſt extenſive and magnificent cities in the world. Riches produced exceſſive luxury and inſolence, in both which reſpects, Capua is particularly noticed by ancient writers. The luxury of Capua is ſaid even to have ſurpaſſed that of Sybaris itſelf. See Athenæus Deipnoſophiſt. l. xii. p. 528. ed. Caſaubon. By its inſolence it exaſperated neighbouring nations, which, on account of its effeminacy, it was not able to repel; and therefore it was reduced to the neceſſity of endangering its own ſafety by engaging the ſuccour of needy auxiliaries. The Roman ſoldiers who were ſent to the defence of Capua, were on the point of making it their prey; and the voice of the Roman people often loudly expreſſed their wiſh for a removal from the barren unwholeſome banks of the Tiber, to the garden of Italy, near thoſe of the Volturno. Jealous, and not without reaſon, of the ambition of Rome, or naturally inconſtant, as Livy and ſome other writers ſuggeſt, the Capuans warmly eſpouſed the quarrel of Carthage: and Hannibal, after the battle of Cannæ, made Capua his winter-quarters. In this ſcene of luxury and diſſipation, if we may credit Livy and ſome other hiſtorians, the rough and invincible ſoldiers of the Carthaginian general were metamorphoſed by pleaſure and indolence into ſoft minions, never afterwards fit to cope with the Romans in the field. Hence, it became a proverb, "Capuam Hannibali Cannas fuiſſe;" i. e. Capua was to Hannibal what Cannæ had been to the Romans. The judicious Monteſquieu obſerves, that the Carthaginian army, enriched by ſo many victories, would have found a Capua wherever they had gone. The pernicious effects of idleneſs and luxury are unqueſtionable; but the frequent defeats which Hannibal afterwards gave to the Romans, the ſeveral towns which he reduced in the ſight of the Roman armies, and the bravery with which he maintained himſelf in Italy for 13 years, after the winter ſpent at Capua, conſtrain us to aſcribe ſome degree of rhetorical exaggeration to the accounts of the Roman hiſtorians. Indeed, Livy himſelf points out a cauſe of the declenſion of the Carthaginian power in Italy, which is very different from the delights and debaucheries of Capua. Hannibal, diſappointed of promiſed ſuccour by a domeſtic faction, and deſerted by the Gauls and Italians, who were not natural allies of the Carthaginians, was under the neceſſity of withdrawing from the ſcene of conteſt, and of yielding to a ſuperior force, which drove him from Italy. Liv. l. xxiii. c. 13 and 32. l. xxvi. Whether Capua brought on the ruin of Hannibal or not, Hannibal, without doubt, occaſioned the ruin of Capua. After the departure of the Carthaginians, Capua, which had been long inveſted, ſurrendered at diſcretion to the conſuls Appius Claudius, and Q. Fulvius Flaccus, in the year of Rome 542. On this occaſion, 80 ſenators were ſcourged and put to death; the nobles impriſoned for life, and the citizens ſold and diſperſed. Vibius, Hannibal's principal friend, eſcaped this ignominious fate by a voluntary death; for whilſt the mob inſiſted upon throwing open the gates to the enemy, he aſſembled his ſteady aſſociates, and ſat down with them to a ſuperb banquet; after which, each of the gueſts ſwallowed a poiſonous draught, and expired in full poſſeſſion of their freedom. Although the buildings were left undemoliſhed, Capua was conſigned to be the lodging place for the huſbandmen of the adjoining plain, a warehouſe for goods, and a granary for corn. However, in proceſs of time, about 152 years after this event, Cæſar ſent thither colonies, and reſtored it to its ancient privileges. Cicero appears to have been the patron of this new city, and to have had in charge the inſpection of the ſea-coaſt from Formiæ, A. U. C. 704, B. C. 50. In this command of Capua he calls himſelf the "epiſcopus" of the Campanian coaſt, and he alſo mentions when proconſul of Cilicia, the "dioceſes" that were annexed to his government; and hence it is inferred, that theſe names, which were afterwards appropriated in the Chriſtian church to characters and powers eccleſiaſtical, carried with them in their original uſe, the notion of a real authority and juriſdiction. See DIOCESE. As Capua had been always the common ſeminary, or place of educating gladiators for the great men of Rome, Cæſar had a famous ſchool of them, at the time when Cicero had the command of it. This ſchool he had maintained under the beſt maſters for the occaſions of his public ſhews in the city; and as they were very numerous, and well furniſhed with arms, there was reaſon to apprehend they would break out, and make ſome attempt in favour of their maſter, which might have been of dangerous conſequence in the then exiſting circumſtances of the republic; and, therefore, Pompey thought it neceſſary to take them out of their ſchool, and diſtribute them among the principal inhabitants of the place, aſſigning two to each maſter of a family, by which he ſecured them from doing any miſchief. Cic. ad. Attic. 7. 14.

Tiberius, A.D. 26, dedicated in this place a temple to Jupiter; and in the reign of Nero, A.D. 57, the colonies of Capua, and alſo of Nocera, which were almoſt extinct, were revived and ſtrengthened by a number of old ſoldiers, ſent thither with the ſame prerogatives as the ancient inhabitants. When the cities of Campania were divided between Vitellius and Veſpaſian, Capua maintained its attachment to the former, and in conſequence of this preference, the third legion was quartered there for the winter, and the moſt illuſtrious families were treated with ignominy. At length, Genſeric the Vandal, in the times of the Lombards, was more cruel than the Roman conquerors had been; for he maſſacred the inhabitants, and burnt the town to the ground. Narſes rebuilt it; but in 841 it was totally deſtroyed by an army of Saracens, and the inhabitants were driven into the mountains. Some time after the retreat of theſe ſavage invaders, the Lombards deſcended again into the plain, but apprehending their force not to be ſufficient for the defence of a circuit ſo extended as the old city, they built a ſmaller one on the river Volturno, chuſing for its ſcite that of Caſilinum, which had diſtinguiſhed itſelf in the ſecond Punic war by the reſiſtance of its garriſon againſt Hannibal, and calling it by the old name of Capua. Since the foundation of the new city, old Capua, diſtant from it about two miles, has remained in ruins, occupying a conſiderable extent of ground. Of theſe, the moſt worthy of notice is the amphitheatre, which, though in a degraded and deſolate ſtate, indicates its former grandeur. Two ſmall villages now occupy part of the ſpacious incloſure of this city, which was the centre from whence the via Appia, via Latina, via Domitia, and others, branched off towards different provinces of Italy. Along the edges of theſe roads the ancients buried their dead in magnificent mauſolea, ſome few of which are yet ſtanding, and point out the direction of the highways. The "conocchia," a vulgar name given to one of theſe monuments, from a ſuppoſed reſemblance to a diſtaff, is the handſomeſt, and conſiſts of a cupola, ſurrounded with columns placed upon a ſquare tower.

In 856, Landulph formed at Capua an independent earldom, diſmembered from the duchy of Benevento; and in the courſe of a few generations, it acquired the title of a principality. In the 11th century, the Normans of Averſa expelled the Lombard race of princes, and Richard their chief became prince of Capua. The grandſon of Tancred of Hauteville drove out the deſcendants of Richard, and united this ſtate to the reſt of his poſſeſſions

Capua is at preſent a neat little city of Naples, in the country of Lavora, ſeated at the foot of a mountain, the ſee of an archbiſhop, founded in 968. It contains, beſide the cathedral, one collegiate, 16 pariſh churches, and 12 convents. It may be conſidered as the key of the kingdom; for though far removed from the frontier, it is the only fortification that really covers the approach to Naples, from which it is diſtant about 15 miles. The ſtreets are more open and airy than thoſe of other towns in this kingdom, and the buildings better. Many of them are conſtructed with materials brought from the ancient city. N. lat. 41° 7′. E. long. 15° 5′.

CAPUCHE. See Cowl, and next article.

CAPUCHINS, religious of the order of St. Francis, in its ſtricteſt obſervance. The capuchins are thus called, from *capuce*, or *capuchon*, a *ſtuff cap*, or *cowl*, wherewith they cover their heads; and which they added to the ordinary Franciſcan habit. They are cloathed with brown or grey; are always bare-footed; and never go in a coach, nor ever ſhave the head.

The Capuchins are a reform made from the order of Minors, commonly called *Cordeliers*, ſet on foot in the ſixteenth century by Matthew de Baſſi, a religious obſervant of the monaſtery of Monteſiaſcone, who, being at Rome, ſaid he was advertiſed ſeveral times from heaven, to practiſe the rule of St. Francis to the letter. Upon this he made application to pope Clement in 1525, who gave him permiſſion to retire into a ſolitude; together with as many others as would embrace the ſtrict obſervance; which ſome did accordingly. In 1528, they obtained the pope's bull. In 1529, the order was brought into complete form; Matthew was elected general, and the chapter made conſtitutions. In 1543, the right of preaching was taken from the Capuchins by the pope; but in 1545, it was reſtored to them again with honour. In 1578, there were ſeventeen general chapters in the order of Capuchins.

The Capuchins were at firſt reſtrained from ſpreading out of Italy; but Charles IX. of France, writing to pope Gregory XIII. to demand ſome Capuchins, that pope, by a bull, dated in 1575, took off the prohibition, and granted them leave to ſettle any where. The cardinal of Lorraine built them a convent at Meudon, and Henry III. another at Paris, in the rue St. Honoré. F. Zach. de Boverio has written the annals of the Capuchins in Latin, in three volumes folio, from the year 1524 to 1634.

Capuchin, in *Ornithology*, the name of a particular ſpecies of pigeon, in ſhape and make much like the jacobine, or jack, but ſomething larger than that; its beak alſo is longer; and it has a tolerable hood of feathers on the back part of its head, but has no cravat or chain down the ſhoulders as that ſpecies has. Its marks are the ſame with the jacobine, and it ſeems to be no other than a baſtard breed between that and a common pigeon.

Capuchin *Monkey*, in *Zoology*. See Capucina Simia.

Capuchin *Powder*, in the *Materia Medica*. See Cevilla, Sabadilla, and Veratrum.

CAPUCIATI, in *Eccleſiaſtical Hiſtory*. an appellation given to the followers of Wickliff in the fourteenth century, by reaſon they did not uncover themſelves before the hoſt, but kept on their *capuce*, or cap uſed in thoſe times. Spondanus ſpeaks of the capuciati, under the year 1387.

Capuciati. See Caputiati.

CAPUCINA, in *Entomology*, a ſpecies of Phalæna, (Bombyx) that inhabits Europe. The wings are dentated and ferruginous, with a dorſal reflected tuft.

Capucina, in *Zoology*, a ſpecies of Simia, of the long-tailed, or ſapajou tribe, called by Pennant the *Capucin monkey*. This kind is diſtinguiſhed by having no beard, the tail hirſute, (and prehenſile): hair and limbs black; haunches covered, or without calloſities. Simia imberbis nigra, cauda longa hirſuta, facie flaveſcente. Linn.

There are three kinds of monkey, ſimia trepida, appella, and capucina, that are nearly allied to each other: ſome conſider the two laſt as varieties of the ſame ſpecies; Schreber makes them diſtinct.

Gmelin deſcribes this animal as being about the ſize of the domeſtic cat: the general colour brown, with the head, legs, and tail black; face ſometimes black, ſometimes fleſh-coloured; tuſks approximate; noſe carinated near the eyes; a black retractile wrinkle juſt under the hair of the forehead; tail long, curved, and ſhaggy, with hair, which it carries ſpirally rolled up, and often coiled round the neck. In the Leverian Muſeum is a ſpecimen of this animal agreeing with the deſcription given of the ſpecies by Mr. Pennant and Dr. Shaw. The face is round, flat, and fleſh-coloured; encircled with upright whitiſh hairs; the breaſt covered with long ſhaggy yellowiſh white hairs; top of the head blackiſh; hair on the ſhoulders and upper part of the back lighter than on the lower part; tail as in the former ſpecies; toes with crooked claws inſtead of flat nails.

Simia capucina is ſaid to be a native of South America. The animal ſmells muſky, has a wailing voice, ſometimes ſhrieks like the cicada, or when irritated yelps like a whelp, and terrifies or repels its enemies by hideous howlings.

CAPUCINUS, in *Conchology*, the name by which Rumpfius diſtinguiſhes *conus monachus* of Linnæus.

Capucinus, in *Entomology*, a ſpecies of Bostrichus in the Fabrician ſyſtem, (*Dermeſtes*, Linn. and *Boſtrichus*, Geoffr.) The colour of this inſect is black, with red abdomen and wing-caſes; and retuſe thorax. Inhabits Europe.

Obſ. Lepechin deſcribes a variety of this inſect with a black abdomen. This is found in Siberia.

Capucinus, the name given by Walch to the Linnæan butterfly, Papilio Iphicla, which ſee.

CAPUL, in *Geography*. See Capoul.

CAPURA, in *Botany*, Linn. Mant. 225. Schreb. 599. Willd. 683. Juſſ. 437. Claſs and order, *hexandria monogynia*.

Gen. Ch. *Cal.* none. *Cor.* monopetalous, tubular; tube cylindrical; border with ſix roundiſh diviſions, the outer alternate ones narrower. *Stam.* Filaments ſcarcely any; anthers ſix, oblong, within the tube; the alternate ones higher. *Piſt.* Germ ſuperior, triangularly roundiſh, truncate; ſtyle cylindrical, very ſhort; ſtigma nearly globular. *Peric.* Berry?

La Marck thinks it has ſome affinity to the genus *Dais.*

Eſſ. Ch. *Calyx* none. *Corolla* ſix-cleft. *Stamens* within the tube. *Stigma* nearly globular.

Sp. C. *purpurata.* A tree. *Branches* alternately in pairs at right angles with each other, purpliſh. *Leaves* deciduous, oppoſite, egg-ſhaped, reſembling thoſe of lonicera xyloſteum, entire, rather acute, on very ſhort petioles. *Flowers* in axillary cluſters, purple, ſhorter than the leaves. A native of the Eaſt Indies.

CAPURSO, in *Geography*, a town of Naples, in the country of Bari; 3½ miles S.E. of Bari.

CAPUT. See HEAD.

CAPUT, in the *Univerſity of Cambridge.* See CAMBRIDGE.

CAPUT *Baroniæ*, the head of the barony, in *Ancient Cuſtoms*, denotes the ancient or chief ſeat or caſtle of a nobleman, where he made his uſual reſidence, and held his court: ſometimes alſo called *caput honoris*, or the head of the honour.

The *caput baroniæ* could not be ſettled in dowry; nor could it be divided among the daughters in caſe there were no ſon to inherit; but was to deſcend entire to the eldeſt daughter, *cæteris filiabus aliunde ſatisfactis.*

CAPUT *Coli*, in *Anatomy*, the commencement of the large inteſtine, which is alſo called the cœcum. See INTESTINE.

CAPUT *Draconis*, a denomination given by ſome to a fixed ſtar of the firſt magnitude, in the head of the conſtellation draco, called alſo by the Arabs *raſaben* and *eltanin.* See NODE.

CAPUT *Gallinaceum*, in *Botany*, Lob. Ic. ii. p. 81. See HEDYSARUM *onobrychis.*

CAPUT *Gallinaginis*, or *Verumontanum*, in *Anatomy*, a ſmall production of the proſtate gland, projecting into the lower part of the urethra, where that canal penetrates the proſtate, and having on its ſurface the openings of the ducts, formed by the union of the vaſa deferentia, and veſiculæ ſeminales. See GENERATION, *Organs of.*

CAPUT *Jejunii*, a name given to Aſh-Wedneſday, as being the firſt day of the Lent-faſt.

CAPUT *Lupinum.* An outlawed felon was anciently ſaid to have *caput lupinum*, and might be knocked on the head like a wolf, becauſe, having renounced all law, he was to be dealt with as in a ſtate of nature, when every one that ſhould find him might ſlay him: but now the wilful killing of ſuch a one is murder, unleſs in the endeavour to apprehend him.

CAPUT *Meduſæ*, in *Aſtronomy*, a northern conſtellation included in that of PERSEUS.

CAPUT *Meduſæ*, in *Botany*, Moriſ. Hiſt. iii. p. 210. See ELYMUS *Caput meduſæ.* See alſo EUPHORBIA *Caput meduſæ.*

CAPUT *Mortuum.*—*Tête morte*, Fr. *Todtenkopfe*, Germ. This term is at preſent obſolete. It was uſed by the old chemiſts to expreſs the reſidues of diſtillations after all the volatile parts had been driven off by the action of heat. Theſe reſidues were at firſt thrown away as of no value. Glauber was the firſt who particularly employed himſelf in their examination, and was rewarded for his pains by the diſcovery of the ſalt that bears his name, (ſulphat of ſoda), in the caput mortuum remaining after the diſtillation of muriatic acid from common ſalt and green vitriol; and of ſulphat of potaſh in the reſidue after the diſtillation of nitric acid from nitre and ſulphat of iron.

CAPUT *Pancreatis*, in *Anatomy*, that portion of the pancreas, which is attached to the duodenum. See PANCREAS.

CAPUT *Porcinum*, *ſwine's head*, a denomination given by the Romans to an order of battle more frequently called *cuneus.*

CAPUT *Purgia*, a barbarous term uſed by ſome phyſicians to denote medicines which cleanſe the head, either in the way of ſneezing, more frequently called *errhines*; or by chewing in the way of ſalivation, called *apophlegmatizants.* See ERRHINA and STERNUTATIVE.

CAPUT-*ſerpentis*, in *Conchology*, a ſpecies of ANOMIA, the ſhell of which is obovate, ſtriated, and downy; one valve with a long perforated beak. Linn. Fn. Suec.

Inhabits the deeps of the Norway ſeas, and is generally found adhering to the *madrepora prolifera.* Shell white, longitudinally ſtriated. Upper valve prominent behind, declining at the anterior part, and marked with a groove in the middle; lower valve rounded, and retuſe before.

CAPUTA, in *Ancient Geography*, a town of Armenia Minor. Ptolemy.

CAPUTIATI, or CAPUCIATI, in *Eccleſiaſtical Hiſtory*, a ſect of fanatics, ſo called from a ſingular kind of cap that was the badge of their faction, which infeſted the province of Burgundy, the dioceſe of Auxerre, and ſeveral other parts of France, towards the cloſe of the 12th century, and excited much diſturbance among the people. They wore upon their caps a leaden image of the Virgin Mary, and they publicly declared that it was their purpoſe to level all diſtinctions, to abrogate magiſtracy, to remove all ſubordination among mankind, and to reſtore that primitive liberty and natural equality that were the ineſtimable privileges of the firſt mortals. They were attacked with the force of arms by Hugo, biſhop of Auxerre. Moſh. Eccl. Hiſt. vol. iii. p. 128.

CAPUTUADE, in *Geography*, a port of Africa, in Byzacium, where the Roman fleet landed the troops that made war againſt Gelimer; diſtant, according to Procopius, five days' journey from Carthage. Juſtinian, he adds, built a town in this place incloſed by ſtrong walls.

CAPYÆ, in *Ancient Geography*, a town of the Peloponneſus, in Arcadia, near Mantinæa, according to Dion. Hal. and Strabo, who ſuppoſed it to have been built by Æneas.

CAPYBARA, or CAEYBARA, in *Zoology*, the American name of a ſpecies of CAVIA, found in that part of the world, and called by Engliſh writers the *water cavy*, or *river cavy.* It is diſtinguiſhed by having no tail, and the fore-feet three-toed, and palmated. See CAVIA.

CAPYS, in *Entomology*, a ſpecies of SPHINX, (Zygæna) of a black colour, with the tip of the anterior pair white. Fabr.—Inhabits Surinam.

CAPYTIUM, in *Ancient Geography*, a town of Sicily. Ptolemy.

CAR. See CARR.

CAR, or KAR, ſignifies in the oriental languages a *town*; and of courſe enters into the compoſition of the names of ſeveral places.

CAR, or CAM LOUGH, in *Geography*, a ſmall lake in the county of Armagh, Ireland, at the foot of Slieve Gullien mountain, from which a narrow and rapid ſtream flows for a courſe of about four miles, when its waters contribute to the ſupply of Newry canal. This lake, river, and a ſmall village, all of the ſame name, are mentioned on account of the great buſineſs done on the banks of the ſtream. So elevated is the ſource of it, that there are a great number of ſcites of mills, all of which are overſhot. So ſudden, indeed, are the falls, that no head of water is required as a mill-pond for any of the works, the tail-race of the higher mill being the head of the next below, and ſo in ſucceſſion until it reaches the valley. In the ſpace of within two miles, there are four extenſive bleach-greens, three of which can finiſh 50,000 webs in a year; a very large boulting-mill, beſide two other flour-mills; a flax-mill, and ſome other manufactories about to be eſtabliſhed. Theſe numerous works furniſh an eminent inſtance of the ſuperior ſpirit and induſtry of the people in this part of Ireland, who ſo eagerly ſeize every natural advantage for furthering and increaſing their trade. Coote's Armagh.

CARA, in *Botany*, Franciſc. Gært. tab. 25. *fig*. 8. See DIOSCOREA *aculeata*.

CARA, in *Geography*, a river of European Ruſſia, which directs its courſe towards the Arctic Ocean, and forms the boundary between Aſia and Europe, for the ſpace of about 140 miles; the Arabian chain terminating ſo far from the ſea of Cara-ſkoi, or Karſkoi.

CARABA, or CRAB-*tree*, in *Botany*, attains in Guiana the height of 40 feet, and conſiſts of numerous branches, covered with long, narrow leaves of a green colour. Its numerous white bloſſoms are ſucceeded by nuts about the ſize of a large cheſnut, the form of which is angular and flattiſh; within the thin, brown, huſky ſhell is contained a white oleaginous kernel. From theſe kernels the Indians extract, by bruiſing, macerating, and boiling, a yellowiſh, bitter, butyraceous oil, with which they conſtantly greaſe and rub their naked ſkins: thus defending themſelves from muſquetoes, ſoftening their ſkins, and preſerving them from taking cold by dews, rain, &c. Bancroft's Guiana, p. 81.

CARABAYA, or CARAVAYA, in *Geography*, a diſtrict or juriſdiction of South America, in the dioceſe of Cuzco, and vice-royalty of Buenos Ayres, commencing 60 leagues S.E. of Cuzco, and extending above 50 leagues. The greater part of it is cold; but the vallies are fertile, producing various ſorts of fruits, grain, and pulſe, and affording ſufficient paſture for cattle of all kinds. This province has ſeveral gold mines, particularly that called "Aporama," which is very rich and the metal 23 carats fine, and alſo ſilver mines, which produce vaſt quantities of that metal. The river which ſeparates this province from the mountains of the wild Indians abounds ſo much in gold, that at certain times the Caziques ſend out a certain number of Indians in companies from the towns in their reſpective diſtricts, to the banks of the river, where, by waſhing the ſands in ſmall wells dug for that purpoſe, they ſoon find ſufficient quantity of gold to pay the royal tribute. This kind of ſervice they call "Chichina."

CARABE, or KARABE, denotes yellow AMBER.

CARABIA, in *Ancient Geography*, a town of Macedonia, placed by Ptolemy in Mygdonia.

CARABIN, or CARBINE, in French *Canon carabiné*, is a fire-arm about a tenth of an inch ſmaller in the bore than a muſket, and about five inches ſhorter, having its barrel about three feet one inch long, and its whole length, including the ſtock, about four feet one inch. Carabines, or canons carabiné, have the outſide of their canons or barrels of the ſame figure and form with thoſe of common muſkets. But they are generally, or at leaſt often rifled on the inſide, having longitudinal grooves ſometimes ſtraight, but much oftener circular or ſpiral, running the whole length of the bore. When grooved, they are generally fired with leaden bullets, that are rammed down along the grooves with iron rammers or ram-rods, which ramming, together with the force and velocity with which they are driven back along the ſame grooves by the inflamed powder, conſiderably alters their ſhape and figure. The common obſervation, however, that a ball ſo rammed down and fired from ſuch a piece goes farther than one of the metal that has windage, in conſequence of its being long enough in the barrel for the complete inflammation of the charge of powder, is founded in miſtake. The grooves, when they are made winding, give the ball a ſort of rotatory motion round its axis in the direction of its flight, that prevents its deflection from the path of its projection.

CARABINEER, or CARBINEER, in French *Carabinier*, was a ſoldier choſen from among the beſt and moſt expert ſhooters, who ſerved ſometimes on foot, but generally on horſeback, and carried a carabine longer than the ordinary fuſee, and commonly rifled. No corps in the French ſervice has diſtinguiſhed itſelf more than the carabineers. They immortalized themſelves at the battle of Fontenoy. Any deficiencies in it, either in men or officers, were filled up from the regiments of French cavalry, according to their ſeniority. As to the time of raiſing it, or its ſeniority of creation, it would have been the twelfth regiment in that ſervice; but in conſequence of ſome other regiments having the name of Royal, and therefore ſtanding before them, it only occupies the twenty-ſecond rank or place.

Formerly, all regiments of light armed horſe were called carabineers. But, ſince the eſtabliſhment of huſſars and chaſſeurs, they have loſt that appellation. And now all the heavy foreign cavalry are denominated carabineers.

CARABINS, otherwiſe called *Argoulets*, were a ſpecies of huſſars in the ancient French militia, and ſometimes acted on foot. There were choſen and reſolute men. All the principal officers of the army uſed to have them as their guards. And they were often ſtationed at the outpoſts for the purpoſe of haraſſing the enemy, guarding narrow paſſes, &c. In action they generally engaged in front of the dragoons, or on the wings of the firſt line. The term comes from the Arabian word *Karab*, which ſignifies generally a warlike inſtrument of any kind.

CARABON, in *Botany*. Lam. Encyc. (Kari-bepou: Rheed. Mal. 4. p. 109. tab. 53. Olea malabarica Nimbo dicta, fructu racemoſo rotundo: Rai. hiſt. 1545.) *Cal.* ſmall, with five acute diviſions. *Cor.* Petals five, lanceolate. *Stam.* Filaments ten, the length of the petals. *Piſt.* germ ſuperior: ſtyle ſmall, whitiſh: ſtigma headed, greeniſh. *Peric.* Berry round, with one ſeed. A large ever-green tree. *Branches* reddiſh, woolly. *Leaves* winged, with a diſagreeable ſmell and a ſouriſh bitter taſte. *Flowers* in terminal panicles, ſmall, whitiſh, with a ſtrong ſmell. An oil is expreſſed from the fruit. A native of Malabar, where it bears flowers and fruit twice in the year. Allied to Melia and Murraya.

CARABUS, in *Entomology*, a genus of Coleopterous inſects that have the antennæ filiform: thorax ſomewhat heart-ſhaped, truncated behind, and with the wing-caſes margined.—This is the eſſential character of the genus carabus, but which is diſtinguiſhed further by having ſix feelers, each of which has the laſt joint obtuſe, and truncated: the abdomen ovate; and the poſterior thighs furniſhed with an appendage at the baſe. The mouth is alſo ſmall, the lip, in ſome entire and truncated as in the true Fabrician carabi: dentated as in his *ſcarites*, or trifid, as in his *manticora*, all which belong to the Linnæan carabi, except a few of the Scarites that are Tenebriones of that author. The legs of the carabi are alſo long, the thighs compreſſed, ſhanks round and ciliated within, the anterior part ſpinous before the tips, and the tarſi of all the legs compoſed of five joints

Olivier divides the Linnæan Carabi into a variety of new genera, as cychrus, caloſome, galerite, brachinus, anthie, manticore, ſcarite, leſteve, and odacanthe. An arrangement ſomewhat ſimilar to this appears in the different ſyſtems propoſed by Fabricius, but not the ſame, and further alterations ſtill have been adopted by other French authors beſides Olivier. We think the carabi may, notwithſtanding, be extremely well diſtinguiſhed by adhering much nearer to the example of Linnæus; the manticora and ſcarites we ſhould ourſelves ſeparate as diſtinct genera from the carabus, but it is impoſſible to conceive the neceſſity of rending the Linnæan genus into ſo many parts as Olivier has to form ſo many new genera:—improvement, and not innovation, ſhould be the leading object of naturaliſts when they preſume to deviate from the authority of their predeceſſors. That the Linnæan carabi, even if we abide by the Linnæan method, ſhould be ſeparated into diſtinct tribes, is ſufficiently apparent to every entomologiſt; we only mean to maintain that by thus dividing them into tribes, they may with few exceptions be retained under one generical title with more convenience, and more propriety, than under ſuch a number of different genera as the French writers are inclined to make of them. Fabricius even ſeems aware of this, for although he forms new genera of part of the Linnæan carabi, his own genus carabus is divided into four diſtinct ſections: * *Thorace cordato.*—** *Thorace poſtice anguſtato.*—*** *Thorace quadrato.*—**** *Thorace rotundato margine prominulo obtuſo.* Mr. Marſham, in his recently publiſhed work, Entomologia Britannica, has alſo ſhewn that it is far better to ſubdivide the Linnæan carabi into ſections than to conſtitute new genera; the ſpecies of carabus found in England, which are thoſe that chiefly demanded his attention, he divides into ſix ſections, in the following manner. 1. Thorace poſticè angulato.—2. Thorace poſtice truncato integro, elytris æquali.—3. Thorace poſticè truncato integro, elytris anguſtiori.—4. Thorace poſticè truncato integro elytris anguſtiori, ſub-elongato, attenuato.—5. Thorace poſticè rotundato.—6. Thorace remoto. Gmelin divides the carabus genus into only two parts, diſtinguiſhing the inſects according to their ſize, *majores* and *minores*, in the laſt edition of the Linnæan Syſtema Naturæ. Turton, in his tranſlation of that work, entirely deviates from his author; he adopts the Fabrician ſubdiviſions, and this is certainly an improvement, but it ſhould have been mentioned as ſuch. The following arrangement of the numerous ſpecies of this genus will be found to correſpond as nearly with the Linnæan and Fabrician authorities as the lateſt obſervations and diſcoveries of authors will conveniently admit.

Many of the inſects of this genus poſſeſs the ſame habits of life. Their larvæ live in the earth, under ſtones, or in decayed wood, and are for the moſt part unknown. In the laſt or perfect ſtate a number of the ſpecies are deſtitute of wings, but they are remarkably active, and run ſwiftly. Some kinds avoiding the light appear only in the night time, while others ramble about in the middle of the day, and ſeem to be moſt vigorous when the ſun ſhines intenſely hot, at which time numbers of them may be ſeen running in pathways, and ſandy places. If theſe inſects are cloſely purſued, they emit a ſtrong, and highly fetid odour, and when caught immediately eject both from the mouth and vent, a duſky greeniſh, or in ſome ſpecies, a reddiſh liquor of an extremely acrid and cauſtic nature, the ſmell of which is ſimilar, but rather more powerful than the odour it ſends forth when purſued. This offenſive humour ſeems to be a proviſion of nature deſigned to compenſate for having denied thoſe creatures wings to facilitate their retreat from other voracious inſects that are furniſhed with wings, the ſmell being alone ſufficiently repulſive, it is reported, in many ſpecies, to check their ferocious purſuers till they can retire to ſome place of ſafety. They can alſo, as we may know by experience when handling them, defend themſelves extremely well by means of their jaws with which they can pinch ſmartly, and no doubt inflict a ſevere wound on the generality of inſects; one or two ſpecies of the winged kind of carabi, if not more, are able alſo to terrify their antagoniſts by making a loud, and frequently repeated ſnapping noiſe, which by ſome has been compared to the exploſion of a muſquet in miniature. This faculty is more completely exemplified in the little ſpecies which the French call *Bombardier*, *Carabus crepitans* of Linn. Faun. Suec. and of later entomologiſts. It has been affirmed by ſome lively writers, that "this inſect poſſeſſes the extraordinary faculty of diſcharging from behind, on being purſued or irritated, a bluiſh, fetid, and penetrating vapour, accompanied by a very ſmart exploſion." "And this operation (it is added) the inſect has the power of repeating ten, twelve, or even twenty times in ſucceſſion with equal violence, thus frequently eſcaping by terrifying its purſuers." (Shaw, Zool.) Another hiſtorian of this pigmy muſqueteer inſiſts that "the ſmoke emitted at the time of each exploſion is ſo denſe as to completely conceal the inſect for the ſpace of a few moments from its purſuers, during which interval the wary creature, like an able warrior, may, and does frequently effect its retreat in good order under cover of the ſmoke occaſioned by its own fire." The recital of this laſt account excites a ſmile; we wiſh that much of the firſt mentioned circumſtances may not prove a goſſip's tale for the credit of thoſe who have aſſented to it. This inſect, it really appears on credible authority, is able to make a loud noiſe, either by means of the vent, or by rubbing its wing-caſes ſmartly together, and to repeat the noiſe at pleaſure, or as its dangers may require; what has been further ſtated muſt be at leaſt received with caution by thoſe diſpoſed even to liſten attentively to reports ſo marvellous.

The ancients conſidered the carabi as poiſonous, and ſuppoſed that if their cattle happened to devour any of them, which muſt often happen when they were grazing, an inflammation of the inteſtines would enſue. The carabi formed alſo an article in their materia medica; both Hippocrates and Pliny ſpeak of them, and attribute to them the ſame properties as the cantharides.

The ſpecies of this genus are as follow.

### Section 1ſt. *Thorax heart-ſhaped.*

Carabus *maxilloſus* of Thunberg, is one of the largeſt ſpecies of this genus. It inhabits the Cape of Good Hope. Olivier deſcribes the ſpecies from a ſpecimen in the Bankſian cabinet. This inſect is apterous; black; mandibles exſerted, and as long as the head; thorax produced behind, and bilobate. Obſ. The antennæ are black with the tips fuſcous; head exſerted, flat in front, with the ſhield rounded and entire; mandibles acute, or pointed at the tips and entire; ſhells glabrous, black, and very ſlightly dotted. Fabr. This muſt not be confounded with manticora maxilloſa of Fabricius, which De Geer calls a carabus (C. tuberculatus.)

Carabus *thoracicus*. Apterous, or without wings, black; thorax lengthened behind into two lobes: ſides and margins of the ſhells villous, white, Fabr. Thunb. Obſ. This is much allied to the preceding inſect, and inhabits the ſame country.

Carabus *coriaceus*, one of the Linnæan ſpecies. This is of the apterous or wingleſs kind; its colour black and opake; ſhells connected, with intricate ſubrugoſe dots. Linn. An inhabitant of Europe, and called by Geoffroy Bupreſtis ater.

Carabus *glabratus*; apterous, entirely black, very ſmooth, and gloſſy. Fabr. Obſ. This is the *Carabus glabratus* of Paykull, and *Carabus convexus* of Herbſt. Inhabits Germany and Sweden.

Carabus *violaceus*, of Linn. and Paykull, is a ſpecies nearly allied to the former. It is apterous, of a black colour, with ſmooth ſhells, the edges of which, and the margin of the thorax are violet.

Carabus *purpuraſcens*, is of the apterous kind, and a black colour, with ſtriated ſhells; margins of the thorax and ſhells violet. Inhabits Germany. Fabr.

Carabus *cyaneus*, *Carabus intricatus* of Linnæus. This is apterous, of a black colour: wing-caſes with rough intricate dots. Paykull, Monog. This is called by Geoffroy *Bupreſtis nigro-violaceus*. Inhabits woods in Europe. Mr. Marſham deſcribes the Linnæan carabus intricatus as an Engliſh ſpecies. Vide Ent. Brit.

Carabus *catenulatus*, of Scopoli. *Carabus prollematicus* of Herbſt. This inſect bears a ſtrong reſemblance to C. purpuraſcens, but has the body ſhorter, and is in other reſpects diſtinct. It is of the apterous kind; colour black; thorax and wing-caſes edged with azure; ſhells ſtriated, and marked with a triple row of impreſſed dots.

Carabus *carolinus*. Apterous, black; thorax and ſhells very ſmooth, and braſſy-green. Inhabits South Carolina.

Deſcribed by Fabricius from the cabinet of Gygot d'Orcy of France. It is of a large ſize with the head black, and braſſy behind; thorax braſſy with an impreſſed dorſal line; ſhells without ſpots; body and legs black. Fabr.

Carabus *hiſpanus*. Apterous, black; thorax azure; wing-caſes rough and golden. Fabr. Found by Prof. Vahl in Spain. Obſ. The body is black; margins of the ſhells azure; legs black.

Carabus *monilis*, a native of Saxony, Hybner. This is black, with the thorax coppery; ſhells ſtriated, coppery-green, with three ſtreaks of oblong elevated dots. Size of the following ſpecies.

Carabus *hortenſis*. Apterous, black, ſhells ſomewhat rough with a triple ſeries of hollow bronzed dots, and azure margin. Linn. A native of Europe, and inhabits England, Donov. Brit. Inſ. This is the *carabus violaceus* of De Geer. Colour variable from black to greeniſh or braſſy-green. Found in gardens chiefly. About an inch in length.

Carabus *gemmatus*. Apterous, black, ſhells ſtriated with a triple ſeries of double, or two-lobed braſſy dots. Fabr. *Carabus ſtriatus* of De Geer. An European ſpecies.

Carabus *concolor*. Apterous, black, wing-caſes ſtriated, with a triple ſeries of excavated dots. Fabr.

This inhabits Germany. Size ſmaller than *carabus hortenſis*. The head is black, gloſſed with copper, and immaculate; thorax black, ſlightly tinged with azure; excavated dots of the ſame colour as the ſhells, not braſſy as in hortenſis, and the body black.

Carabus *tædatus*. A North American ſpecies of the apterous kind, and black colour; ſhells ſomewhat ſmooth, fuſcous, with a triple ſeries of excavated dots. Fabr. Obſ. The ſuture of the ſhells is black.

Carabus *irregularis*. This is apterous; head and thorax coppery: ſhells more duſky, with the margins, and triple ſeries of excavated dots coppery. Found in decayed beech trees in Europe. Helwig.

This reſembles *carabus hortenſis*: the antennæ are black with the firſt joint ferruginous, its head coppery, and mouth black; ſhells irregularly punctured; and body black.

Carabus *arvenſis*. Apterous, black, and coppery; ſhells ſtriated with a triple ſeries of hollow dots. Paykull, Monogr. Inhabits Europe, principally Germany. Probably the ſame as *Carabus catenulatus*, Marſh. Ent. Brit.

Carabus *hungaricus*. Apterous, black; ſhells very ſmooth, and punctured with a triple row of black dots. Inhabits Hungary, Smidt. Obſ. The body is entirely black, and the margins are not bluiſh, as in ſome analogous inſects.

Carabus *retuſus*. An inſect the ſize of C. *hortenſis*, found on the ſhores of Patagonia, and preſerved in the Bankſian cabinet. This is apterous; ſhells ſtriated, greeniſh, with a triple ſeries of braſſy hollow dots, and retuſe at the baſe. Fabr. Obſ. The antennæ of this inſect are brown, but at the baſe black; the head greeniſh, with black mouth; thorax green and impreſſed on each ſide at the baſe; ſhells with crenated ſtriæ; body black.

Carabus *Maderæ*. Apterous, black, with the ſhells retuſe at the baſe.

Deſcribed by Fabricius from a ſpecimen in the Bankſian cabinet found at Madeira. Much allied to the preceding; the antennæ black with fuſcous apex; ſhells ſlightly ſtriated, and marked with a triple ſeries of minute greeniſh impreſſed dots: legs black.

Carabus *convexus*. Apterous, convex, black, ſmooth, with the poſterior part of the thorax emarginate. Paykull. A native of Germany.

Carabus *auratus*. Apterous; ſhells golden and furrowed; antennæ and legs rufous. Linn. Inhabits Europe.

Carabus *ſplendens*. Apterous; above bronzed, and gloſſy, ſuture of the ſhells coppery. Found in Jamaica. Boſe. Obſ. This is a large ſpecies. The head is marked with two furrows, and braſſy, its mouth and antennæ black; ſhells very ſmooth; body black. *Carabus ſplendidus* of Gmelin.

Carabus *ſuturalis*. An inſect reſembling the foregoing that inhabits Terra del Fuego, deſcribed by Fabricius, from a ſpecimen in the Bankſian cabinet. This is of the apterous kind; ſhells ſtriated, and greeniſh with golden ſuture.

The antennæ of this ſpecies are dark brown, ferruginous at the baſe; head green, mouth fuſcous; thorax green with golden margin; ſhells ſlightly ſtriated with a triple ſeries of ferruginous dots; breaſt greeniſh; legs ferruginous.

Carabus *nitens*. Apterous; ſhells rough, greeniſh, with longitudinal raiſed lines, golden margin, and black legs. Linn. *Carabus auræus* of Degeer.

Carabus *auronitens*. Nearly allied to the former; it is of the apterous kind, with rough greeniſh ſhells marked with three longitudinal raiſed lines, and rufous thighs. Inhabits Germany.

Carabus *morbilloſus*. Apterous; thorax coppery; ſhells ſtriated, coppery, with longitudinal elevated dots, and rugged furrows. Fabr.

Carabus *rugoſus*. Apterous, black; ſhells with rugoſe ſtriæ, and three rows of elevated dots between them. Deſcribed by Fabricius from the cabinet of Seheſtedt as a native of Morocco; it is twice the ſize of carabus granulatus.

Carabus *clathatus*. Apterous, blackiſh-braſſy, with rows of coppery excavated dots between the ſtriæ. Linn. Inhabits Europe.

Carabus *granulatus*. Apterous, blackiſh; ſhells braſſy, with rows of oblong raiſed dots between the ſtriæ. Linn, &c. Inhabits Europe.

Carabus *roſtratus*. Apterous; ſhells ſmooth, and black, and wider than the thorax; head very narrow.

This is an European ſpecies, and has been deſcribed by authors under various names; Degeer calls it carabus coadunatus, Linnæus tenebrio roſtratus, and Paykull as well as Fabricius carabus roſtratus, and by Fabricius in his appendix cychrus roſtratus.

Carabus *attenuatus*. Apterous, black, ſhells ſlightly gloſſed with coppery, with a triple ſeries of elevated dots; thorax narrower; head very narrow. Panzer, &c. This inhabits Europe, particularly Germany: in the laſt work of Fabricius it ſtands in the new genus cychrus under the ſpecific name of *attenuatus*.

Carabus *elevatus*. Apterous; thorax with reflected margin; ſhells violaceous; body black. Fabricius.

This and the following ſpecies inhabit South America, and are deſcribed from the Hunterian muſeum.

Carabus *unicolor*. Apterous; thorax with reflected margin; body black, and ſhells ſtriated.

Carabus *attelaboides*. Apterous, black; thorax ſomewhat heart-ſhaped, and narrow; head attenuated behind; ſhells grooved and furrowed. Fabr. An Indian ſpecies, in the Bankſian cabinet.

Carabus *leucophthalmus*. Apterous, black; ſhells ſtriated; thorax with ſhort impreſſed lines at the baſe. Linn. Inhabits Europe, and is found in England.

Carabus *planus*. Winged, depreſſed, black, with ſlightly ſtriated wing-caſes. Fabr. Ent. Syſt. *Carabus ſpiniger* of Paykull, and *carabus obſoletus* of Faun. Etruſc. Obſ. Mr. Marſham in his Ent. Brit. conſiders this inſect the ſame as the foregoing; namely, carabus leucophthalmus of Linn. Fabricius tells us it is rather larger, and has the body entirely black, and without ſpots; thorax heartſhaped, ſmooth, and without the little impreſſed lines at the baſe as in the former inſect.

Carabus *ſtriatulus*. Winged, black; thorax at the baſe with an impreſſed dot; wing-caſes ſtriated, and glabrous in the middle. Deſcribed by Fabricius from the Bankſian cabinet. Inhabits the ſhores of Patagonia.

Carabus *ſabuloſus*. Winged, pale; head, and dorſal ſpot on the body black. Fabr. A native of Saxony.

Carabus *arenarius*. Winged, pale; with two black dorſal ſpots on the wing-caſes. Inhabits ſandy ſhores of Wales. Deſcribed from the Bankſian cabinet. Fabr.

Carabus *lateralis*. Winged, black; thorax and ſhells margined with ferruginous. An European ſpecies, and inhabits woods. Daldorf.

Carabus *ruficornis*. Winged, black; wing-caſes furrowed, and ſlightly downy; antennæ and legs rufous. Paykull, &c. Common in woods in Europe. Inhabits England. Liſter, Marſham, &c.

Carabus *picicornis*. An Italian ſpecies of the winged kind, with the head, antennæ, and legs rufous. Muſ. Allioni.

Carabus *flavicornis*. Winged, black; margin of the thorax, with the antennæ, and legs yellowiſh. Paykull. Inhabits Saxony. Hybner.

Carabus *fulvipes*. Winged, black; thorax canaliculated; ſhells ſtriated and ſmooth; antennæ and legs ſmooth. Inhabits the woods in Germany. Smidt.

Carabus *piceus*. Winged; thorax grooved with two ſtriæ on each ſide; antennæ and ſhanks of the legs piceous, or pitchy. Linn. and Schæffer. Found in European woods.

Carabus *femoralis*. Winged; head and thorax braſſy; wing-caſes duſky, and ſtriated; thighs rufous. Inhabits Sierra Leona. Bankſian cabinet.

Carabus *terricola*. Winged, black, and gloſſy; wing-caſes with ſmooth ſtriæ; extremity of the antennæ, and the legs rufous. Paykull, Monogr. Inhabits Germany, and is found under ſtones. Fabr.

Carabus *madidus*. Winged; thorax with an impreſſed black dot on each ſide at the baſe; thighs rufous. Paykull. Inhabits England.

Carabus *americanus*. Winged, black; thorax, antennæ, and legs ferruginous. A native of America.

Carabus *janus*. Winged; thorax ferruginous; wing-caſes azure. Fabr. *Carabus bicolor* of Olivier. Inhabits Carolina. Obſ. The antennæ are villous, black, with the firſt joint rufous: head advanced, cylindrical, and brown; body black, with ferruginous feet.

Carabus *fumans*. Winged, entirely ferruginous, except the wing-caſes, which are blue-black. Inhabits America.

Carabus *crepitans*. Winged; head, thorax, and legs ferruginous; wing-caſes black. Linn. Le bupreſte à téte, corcelet et pattes rouges et ètuis bleus. Geoffr.

This is the bombardier of French writers mentioned in the introduction, which is ſaid to poſſeſs the faculty of terrifying its enemies by repeated loud exploſions and fetid vapours emitted from the vent, whence its name crepitans, "Terrefactus crepitu ani hoſtem pellere tentat." This ſingular ſpecies inhabits Europe. Mr. Marſham deſcribes it as a native of this country. Ent. Brit. Fabricius ſpeaks of a variety of this ſpecies about half the ſize, that occurs in Germany.

Carabus *ſclopeta*. Ferruginous; wing-caſes azure; with the future at the baſe ferruginous. Fabr. Found abundant in France under ſtones. It is much ſmaller than C. crepitans; there is a rare variety of it in which the future is the ſame colour as the wing-caſes.

Carabus *ſpinibarbis*. Winged, azure; mouth, antennæ, and ſhanks rufous. Inhabits England. Marſham.

Carabus *æneocephalus*. Winged, bluiſh-black with ſtriated wing-caſes, and a rufous ſpot on the poſterior part. Fabr.

An inhabitant of the South American iſlands, and allied in appearance to the former. The head is braſſy-green, and gloſſy. Antennæ black, with the firſt joint rufous. Thorax heart-ſhaped, punctured, braſſy-green with a ſmall impreſſed line on each ſide at the baſe.

Carabus *humeralis*. Winged, black with ſtriated wing-caſes; ſpot at the baſe, and the legs rufous. Inhabits Italy. Allioni.

Carabus *trilobus*. Winged, braſſy-green; wing-caſes with two white ſpots; antennæ and legs yellow. A native of Guinea. Iſert.

Carabus *multipunctatus*. Winged, ſomewhat braſſy with numerous irregular impreſſed dots. Linn, Paykull, &c. Inhabits Europe.

Carabus *oblongopunctatus*. Winged, black, with ſtriated wing-caſes, and numerous impreſſed dorſal ſpots. Inhabits Germany.

Carabus *varioloſus*. Thorax ſomewhat cordated or heart-ſhaped; black; ſhells azure; baſe of the abdomen and legs rufous. Fabr. Inhabits Auſtria.

Carabus *axillaris*. Ferruginous; ſhells ſtriated, and black, with a pale ſpot at the baſe. Inhabits Auſtria. Fabr.

Carabus *cinctus*. Winged, fuſcous; head and thorax braſſy-green; margins of the wing-caſes, and legs pale. Inhabits Coromandel. Bankſian cabinet.

Carabus *rufipes*. Winged, black; antennæ, legs, and margin of the wing caſes rufous. Fabr. Muſ. Lund. Native place unknown.

Carabus *nitidulus*. Winged, black; margin of the wing-caſes ſhining-braſſy. Inhabits Kamtſchatka. Bankſian cabinet. Obſ. The head and thorax black, gloſſed with coppery; wing-caſes ſtriated, the ſtriæ punctured alternately. Legs black.

Carabus *Dianæ.* Winged, black; wing-caſes ſtriated; lunule at the baſe, and the legs ferruginous. Inhabits Saxony. Hybner, &c.

This is of the middle ſize; head ſmooth, black; antennæ ferruginous. Thorax heart-ſhaped, and grooved; body black; legs ferruginous.

Carabus *agilis.* Winged, rufous; wing-caſes and abdomen black. Paykull. Inhabits Sweden. The crown of the head is black, and the wing-caſes truncated.

Carabus *ruficollis.* Winged; thorax ferruginous; wing-caſes truncated, ſtriated, greeniſh; head flat, and black. Fabr.

Deſcribed as a native of South America from a ſpecimen in the cabinet of Dr. Hunter. It is of the middle ſize; antennæ black, with fuſcous tips; thorax elongated, heart-ſhaped, and ſlightly grooved; wing-caſes ſhining; abdomen black with ferruginous vent; legs black, thighs rufous at the baſe.

Carabus *olens.* Winged; thorax rufous; wing-caſes fuſcous with three rufous ſpots. Inhabits Italy. Boſc.

This inſect very much reſembles a cicindela. The body is of the middle ſize, elongated, and more depreſſed than uſual in the carabus genus. The antennæ are ferruginous, with the firſt joint longeſt, incurvated, and thick at the end; head black and gloſſy, mouth ferruginous; ſhells ſlightly ſtriated; legs rufous.

Carabus *faſciatus.* Winged; thorax rufous; ſhells yellowiſh with a common black band. Paykull, &c. Inhabits Sweden.

Carabus *atricapillus.* Winged; thorax rufous; wing-caſes teſtaceous, and obtuſe; head black. Linn. Inhabits Europe. Conſidered by Fabricius and others as a variety only of Paykull's carabus agilis. It varies frequently in having the margins of the ſhells black. This inſect is found in England.

Carabus *4-puſtulatus.* Winged, yellow, with fuſcous wing-caſes, each marked with two yellow ſpots. Fabr.

Inhabits Africa. Deſcribed from the Bankſian cabinet. This is an inſect of ſmall ſize; its antennæ are fuſcous; thorax heart-ſhaped, yellow with an impreſſed dorſal line; wing-caſes ſlightly ſtriated and truncated.

Carabus *oblongus.* Winged, black; thorax oblong; wing-caſes ſtriated, fuſcous, with yellow antennæ and legs. A native of Germany. Smidt. Obſ. This is a ſmall inſect, with a black ſhining head, and yellow feelers; thorax grooved, black, and ſhining; ſtriæ on the wing-caſes crenated; abdomen pitchy.

Carabus *rubens.* Winged; thorax ferruginous; wing-caſes rounded, teſtaceous, with the head fuſcous. Inhabits Germany. Fabr. This very much reſembles carabus atricapillus; the ſhells are ſtriated, and without ſpots; the head fuſcous.

2d Section. *Thorax narrowed behind.*

Carabus *venator.* Apterous, black, with ſmooth wing-caſes, and a grey ſpot at the baſe. Inhabits Senegal. Olivier. Obſ. The head is advanced, and very large, with each ſide of the front impreſſed; thorax behind with acute margin; wing-caſes glabrous, and ſmooth.

Carabus *ſulcatus.* Apterous, black, with margin of the thorax white; wing-caſes furrowed, margin and three ſpots white. Olivier. This inhabits Senegal, and reſembles the preceding; at the baſe of the wing-caſes is a ſmall oblique white line, a white dot before, another behind the middle, and one at the apex.

Carabus *nimrod.* Apterous, black; wing-caſes furrowed with two remote villous grey ſpots. Olivier. This alſo is a native of Senegal. The body is black; thorax immaculate.

Carabus *10-guttatus.* Apterous, black; ſhells with nine furrows, and ten white dots. Linn. Inhabits Africa. Called by Degeer carabus alboguttatus.

Carabus *6-guttatus.* Apterous, black; wing-caſes ſmooth; with two grey ſpots. Inhabits India. Olivier, Donov. Inſ. Ind. &c. This is of a large ſize; the ſhield is ſquare, and entire: jaws advanced, bent, and pointed; legs black.

Carabus *4-guttatus.* Apterous, black; thorax with two large pitchy tubercles, and a ſmall grey dot on each ſide; wing-caſes furrowed; with elevated carinated lines, and two remote grey ſpots. A native of Africa.

Carabus *7-guttatus.* Apterous, black; above brown; ſhells ſtriated with ſeven white dots. Fabr. Inhabits the Cape of Good Hope.

Carabus *tabidus.* Apterous, black; wing-caſes with rugoſe furrows. Fabricius.

Deſcribed from the Bankſian cabinet as a native of the Cape of Good Hope. Its ſize is about half that of carabus 4-guttatus; the front is grooved on each ſide; thorax with two raiſed dorſal lines on the back part; wing-caſes rather pointed behind; body deep black.

Carabus *nigripennis.* Apterous, rufous; ſhells grooved, and black. Inhabits the Cape of Good Hope. Voet. &c.

Carabus *variegatus.* Apterous; wing-caſes flat and ſmooth, with white ſinuate margin and ſpots on the diſk. A native of the Eaſt Indies, deſcribed by Forſkal. Obſ. The eyes are teſtaceous; lateral margin of the thorax whitiſh; wing-caſes with five white dots in the diſk; body black.

Carabus *exclamationis.* Apterous; margin of the thorax white; wing-caſes with a white margin, line, and dot in the middle. Fabricius. From Barbary.

Carabus *trilineatus.* Apterous, black; edges of the thorax white; wing-caſes whitiſh, with black line and future. Inhabits Germany. Deſcribed by Thunberg under the name of carabus lineatus.

Carabus *cephalotes.* Winged, black, very ſmooth, with convex thorax. Linn.

Carabus *cicindeloides.* Apterous, and black; wing-caſes ovate, flat, ferruginous, and villous edged with white. Inhabits the Cape of Good Hope, Stockh. Tranſ.

Carabus *lævigatus.* Winged, black, depreſſed; thorax and ſhells very ſmooth. Inhabits Coromandel.

Carabus *interruptus.* Winged, black; thorax and wing-caſes remote. Inhabits the Eaſt Indies. Herbſt. Scarites clypeatus. Roſſi.

Carabus *tricuſpidatus.* Winged, black; antennæ, and legs ferruginous; ſhield tricuſpidate. Inhabits Barbary. Muſ. Desfontaines.

Carabus *calydonius.* Winged; head with an obtuſe projecting horn; mandibles horned.

Scarites calydonius, Roſſi. This kind inhabits Italy. The head is large with a large obtuſe compreſſed horn in front; mandibles with a ſtrong recurved tooth; ſhells punctured in ſtriæ.

Carabus *complanatus.* Winged, yellowiſh, with two black bands on the wing-caſes. Linn. Found in St. Domingo.

Carabus *bimaculatus.* Winged, black; head and wing caſes truncated; dot at the baſe, and band in the middle ferruginous. Linn. Inhabits India. Donov. Inſ. Ind. Obſ. The thorax is variable in this ſpecies, being ſometimes yellow, ſometimes black, and not unfrequently ſpotted.

Carabus *tripuſtulatus.* Winged, black; with two yellow ſpots on each wing-caſe, the poſterior ones approximate; legs yellow.

A native of Siam. Size of the laſt ſpecies, and which, as Fabricius intimates, may prove to be only a variety of it. The head is flat, ſmooth, and black, with the mouth teſtaceous; thorax flat, ſmooth, black and without ſpots; wing-caſes ſtriated, black with two large yellow ſpots; the legs yellow, with a ſingle tooth on the anterior ſhanks.

Carabus 6-*puſtulatus*. Rufous with black wing-caſes, and three red dots. Inhabits the Eaſt Indies. Edler.

The head and thorax are rufous; wing-caſes ſtriated, and black, the red ſpot at the tip lunate; abdomen rufous with black margin; legs rufous.

3d Section. *Thorax ſquare.*

Carabus *varioloſus*. Apterous, black; ſhells ſprinkled with irregular impreſſed dots.

Inhabits Tranſylvania. Saldoner. It is of a large ſize, and entirely black: antennæ black with fuſcous tips; thorax margined; ſhells connected, and variouſly ſprinkled with large irregular impreſſed dots, ſome of which are confluent.

Carabus *ſtriola*. Apterous, depreſſed; black; two impreſſed lines on each ſide of the thorax at the baſe; ſhells ſtriated. Fabr.

Much allied to carabus leucophthalmus, but is broader, and more depreſſed; the colour is entirely black. Inhabits Saxony.

Carabus *metallicus*. Apterous, black, with a ſmall impreſſed line on each ſide of the thorax at the baſe; thorax and ſhells braſſy. A native of Saxony. Smaller than the preceding. Head black; feelers ſomewhat ferruginous; thorax braſſy, ſhining, and grooved in the middle; ſhells ſlightly ſtriated; body black. There is a variety of it with duſky thorax; and coppery ſhells. Hybner, &c.

Carabus *politus*. Winged, gloſſy-black; wing-caſes ſtriated; antennæ rufous. Inhabits the Eaſt Indies.

Deſcribed from the cabinet of Lund. In ſize and appearance it much reſembles C. leucophthalmus; the head is large and exſerted; antennæ rufous with the firſt joint black; lip heart-ſhaped; jaws ſtrong and thick at the extremity; thorax grooved; body black.

4th Section. *Thorax rounded, with a ſlightly prominent obtuſe margin.*

Carabus *alternans*. Apterous, black; ſhells with reticulated ſtriæ, which are broader alternately, and marked with a triple ſeries of elevated braſſy-dots retuſe at the tip. Fabricius.

This inſect reſembles the next ſpecies; the antennæ are black, cinereous at the tip; head large; eyes globular, prominent, and teſtaceous; thorax black, and immaculate; ſhells deeply ſtriated, and interſected with ſmaller ones, the longitudinal ſtriæ alternately broader; and three ſtreaks of oblong raiſed braſſy dots; legs black. Inhabits South American iſlands.

Carabus *calidus*. Apterous, black; ſhells with crenated ſtriæ; the ſtriæ equal, and marked with a triple row of indented golden dots. Inhabits South American iſlands. Muſ. von Rohr. Obſ. The antennæ are reddiſh at the tip, and on each ſide near the baſe of the wing-caſes is a ſingle golden dot.

Carabus *ſericeus*. Apterous, black; an impreſſed dot on each ſide the thorax at the baſe; ſhells ſomewhat ſtriated, with a triple row of braſſy dots. Inhabits Germany. Smidt. Allied to the two preceding, but diſtinct. The antennæ are black, at the tip fuſcous; head black; thorax and body black. Fabr.

Carabus *porcatus*. Apterous, black; ſhells ſtriated and granulated at the tip.

Inhabits New Holland, and is deſcribed by Fabricius from a ſpecimen in the Bankſian cabinet. This is of a moderate ſize.

Carabus *reflexus*. Apterous, black; wing-caſes furrowed, with two yellow ſpots. Inhabits Coromandel. Obſ. The head is black, and impreſſed on each ſide; thorax unequally punctured, and ſlightly reflected at the edge; ſhells connected, with eight grooves; legs black.

Carabus *angulatus*. Apterous, hairy, and black; thorax canaliculated; ſhells grooved, with two interrupted yellow bands. Inhabits Coromandel. Fabr.

Carabus *caſſideus*. Apterous, black; thorax margined; ſhells ſmooth. Found in France. Boſc.

Carabus *ſilphoides*. Apterous, black, with margined thorax; ſhells ſtriated, punctured, with rows of larger punctures. Inhabits France and Italy. Roſſi.

Carabus *globoſus*. Apterous, black, with convex thorax, and ſtriated ſhells. A native of Morocco. Scheſtedt.

Carabus *indagator*. Apterous; ſhells very ſmooth, with a triple row of braſſy dots. Inhabits Barbary. Believed to be the *carabus auropunctatus* of Paykull.

Carabus *ſycophanta*. Winged; gloſſy-violet; wing-caſes golden and ſtriated. Linn. Inhabits woods in Europe.

Carabus *inquiſitor*. Winged; wing-caſes ſtriated, braſſy-green, with a triple ſeries of dots. Linn. A native of Europe, and frequents woods.

Carabus *ſcrutator*. Winged; wing-caſes ſtriated, greeniſh, with a triple ſeries of dots; thorax azure; margin reflected and golden. Inhabits Virginia. Fabricius.

Carabus *reticulatus*. Winged, black; wing-caſes reticulated, braſſy-green; the margin of the thorax greeniſh. Inhabits Europe. Zſchuck.

In ſize and appearance reſembles carabus inquiſitor; the antennæ are black, with the laſt joint ferruginous; wing-caſes very finely reticulated.

Carabus *longicornis*. Winged, black; head and thorax dotted; wing-caſes with crenated ſtriæ; antennæ and legs ferruginous. A native of Morocco. Fabr. Obſ. The antennæ are nearly as long as the body, whence its ſpecific name longicornis: the head is black, with ferruginous feelers; thorax rounded at the ſides, dotted, and black; wing-caſes black, and without ſpots; thighs blackiſh.

Carabus *brevicollis*. Winged, black, with ferruginous antennæ.

This inſect inhabits Germany. Helwig.

Carabus *rotundicollis*. Pitchy-ferruginous; ſhells paler antennæ and legs pale teſtaceous. Inhabits England. Marſh. Ent. Brit.

Carabus *ochropus*. Pitchy black; antennæ and legs pale teſtaceous. A native of England. Marſham.

Carabus *punctulatus*. Winged, depreſſed, black; ſhells punctured, ſlightly ſtriated, and retuſe at the baſe. Inhabits Saxony. Paykull, &c.

The head is ſmooth and black; antennæ ſhort and browniſh; thorax ſmooth, black, and immaculate; wing-caſes nearly ſmooth; body black; ſhanks of the legs ſpinous.

Carabus *obſcurus*. Black and winged; thorax dotted; wing-caſes ſtriated; legs piceous. Inhabits Saxony, Hybner; and England, Marſham. Rather larger than carabus ruficornis.

Carabus *micans*. Winged; ſhells ſhining gold with a teſtaceous ſpot at the tip; legs rufous. Country unknown. Boſc. Obſ. The head is ſmooth and coppery; thorax grooved, and gloſſed with green; body black.

Carabus *bicolor*. Winged; above black, beneath ferruginous. Inhabits North America. This reſembles carabus obſcurus, but differs in having all the lower ſurface with the legs and antennæ ferruginous.

Carabus *holoſericeus*. Winged, ſilky-black; head braſſy and ſhining. Fabr. Obſ. The head is braſſy, with the mouth and antennæ black; wing-caſes ſtriated: legs black.

Carabus *ſulcatus*. Winged, black; thorax variolous; wing-caſes grooved, with a ferruginous ſpot in the middle. Found at the Cape of Good Hope. Fabr.

Carabus 2-*notatus*. Winged, black; head with two rufous dots in front; antennæ yellow at the baſe. Inhabits Germany. Daldorf.

The body of this ſpecies is entirely black; head ſmooth and gloſſy; thorax ſmooth; wing-caſes ſtriated; legs variable from red to black.

Carabus *fulvicollis*. Winged, azure; mouth, thorax, and thighs rufous; wing-caſes ſtriated, and truncated. Inhabits Barbary. Fabr.

Carabus *pilicornis*. Winged; ſhells ſtriated with impreſſed dots; antennæ hairy. Fabr. Inhabits England. Donov. Brit. Inſ.

Carabus *ſemipunctatus*. Winged; thorax roundiſh; wing-caſes fuſcous, ſtriated, with anterior hyaline ſpots, and dots on the poſterior half. A new ſpecies lately diſcovered in South Wales. Donov. Tour. 1805.

Carabus *cæruleſcens*. Winged, bluiſh black, with ſtriated wing-caſes; antennæ at the baſe red. Linn. *Carabus virens*. Myller. Obſ. This ſpecies varies in colour from bluiſh to braſſy, coppery and green.

Carabus *lepidus*. Winged, braſſy-green; thorax with two ſtriæ on each ſide; wing-caſes ſtriated. Fabr. *Carabus lepidus*. Leſke. Itin. A native of Europe.

Carabus *ſchach*. Winged, black, with ſtriated wing-caſes, and a large oblong ſpot behind; antennæ and legs rufous.

This kind inhabits South America, and reſembles in ſize and appearance carabus pilicornis. The head is black; ſtriæ on the wing-caſes crenated; body black.

Carabus *cupreus*. Winged, coppery; baſe of the antennæ red. Linn. Inhabits woods in Europe.

Carabus *carnifex*. Winged, braſſy-green; antennæ and legs rufous. Found in Terra del Fuego. Bankſian Cabinet.

This is of a ſmall ſize; head braſſy, and ſhining; mouth ferruginous, poſterior part of the thorax with an impreſſion on each ſide; wing-caſes ſtriated, and ſubretuſe at the tip.

Carabus *vulgaris*. Winged, braſſy-black; antennæ and legs black. Linn. Very common in ſandy places in Europe. Obſ. This is *carabus ovatus* of Roſſi, Helw. &c. and *carabus affinis*, Schrank.

Carabus *communis*. Winged, braſſy; antennæ at the baſe and the ſhanks rufous. Marſham, Panzer. Rather ſmaller than the former, and is found in ſimilar ſituations. Panzer ſpeaks of a variety that has the legs entirely rufous inſtead of the ſhanks only.

Carabus *ovatus*. Winged, black; ſhells ſtriated and ſmooth; antennæ and legs ferruginous. Fabricius. Inhabits Saxony.

Carabus *latus*. Winged, black; ſhells with crenated ſtriæ, antennæ and legs ferruginous. Linn. Inhabits Europe. The ſpecies is ſometimes found in England, in woods.

Carabus *abdominalis*. Winged, black; antennæ, diſk of the abdomen, and legs ferruginous. Inhabits the Cape of Good Hope. Fabr.

Reſembles the former in ſize and aſpect; the head is black; feelers ferruginous; thorax ſmooth and black; ſhells ſtriated, black, and without ſpots.

Carabus *helopioides*. Winged, black; wing-caſes with ſmooth ſtriæ; antennæ and legs black. A native of Germany. Helwig. Entirely reſembles the Fabrician *carabus ovatus*, except in being totally black.

Carabus *azureus*. Winged, azure; antennæ and legs red. Bergſtr. Nomencl. Inhabits Germany.

Carabus *erythrocephalus*. Winged, black; head rufous; antennæ and legs yellow. Fabr.

This is a native of Germany, and is of a moderate ſize; the thorax is black and gloſſy; wing-caſes ſtriated and black.

Carabus *analis*. Winged, black; mouth, antennæ, vent, and legs ferruginous. Fabr. This reſembles the former in ſize and aſpect; the head is black; thorax black, with an impreſſed dorſal line, and two little impreſſed lines at the baſe; wing-caſes black, with crenated ſtriæ. Inhabits Germany. Smidt.

Carabus *lineola*. Winged, ferruginous, with a ſmall black line on the wing-caſes. Deſcribed from the Bankſian Cabinet. The ſpecies inhabits North America.

Carabus *ferrugineus*. Winged, ferruginous, and entirely convex. Marſh. Inhabits England, and the reſt of Europe. C. *ferrugineus* of Linn. Paykull, &c.

Carabus *ruſimanus*. Winged, black, and convex; antennæ and ſoles of the feet ferruginous. Marſh. Inhabits England.

Carabus *paliens*. Winged, pale, with ſtriated wing-caſes. Fabr. Is found in Saxony.

Carabus *Surinamenſis*. Winged, teſtaceous; thorax and wing-caſes ſtriated and fuſcous. Inhabits Surinam.

Carabus *dorſiger*. Winged, ferruginous; ſhells with a broad black lunule; abdomen black. Fabr.

This is a native of Barbary. The head is duſky; ſhells ſtriated; legs ferruginous.

Carabus *aterrimus*. Winged; thorax margined, black; wing-caſes black, ſtriated, with three impreſſed dots. Inhabits woods in Europe. Fabr. &c.

Carabus *æneus*. Winged, above braſſy; antennæ and legs ferruginous. Fabr. This is an European ſpecies, and inhabits England. The body varies from black to ferruginous.

Carabus *nigricornis*. Winged, green, downy, with numerous punctures; thorax ſhining golden; wing-caſes with obſolete ſtriæ and duſky; legs piceous. Marſh. Inhabits England. Obſ. This is *carabus nitidulus* of Thunberg.

Carabus *parumpunctatus*. Winged, oblong, and braſſy above; beneath black; wing-caſes ſtriated, with ſix impreſſed dots; ſhanks piceous. Fabr. Found in Germany.

Carabus 6-*punctatus*. Winged; head and thorax greeniſh; wing-caſes coppery. Linn. An European ſpecies.

Carabus *diſcoideus*. Winged, black, outer margin of the wing-caſes, with the antennæ, rufous. Inhabits Germany. Smidt.

Carabus *marginatus*. Winged, green, margin of the wing-caſes and the ſhanks teſtaceous. Linn. Inhabits woods in Europe.

Carabus *veſtitus* of Paykull and Fabricius is ſuppoſed to be a variety of the Linnæan *carabus marginatus*. It is of the winged kind, green-braſſy colour, with the edges of the thorax, and wing-caſes, with the antennæ and legs pale. Geoffr. Fabr. &c. Inhabits Hungary.

Carabus *pallipes*. Winged, black; border of the thorax and wing-caſes, with the legs pale. Deſcribed by Fabricius from the Hunterian Muſeum, as a native of America. Obſ. The antennæ are black pale at the baſe; head black, with ferruginous mouth; ſhells ſtriated; body black.

Carabus *fuſcus.* Winged, fuſcous; wing-caſes obſoletely ſtriated; antennæ, margin of the thorax, and legs yellow. Inhabits Germany.

Carabus *nigrita.* Winged, black and gloſſy; thorax caniculated; wing-caſes ſtriated. A native of Europe.

Carabus *quadrum.* Winged; thorax rounded, black; wing-caſes ſtriated with a pale ſtripe. Inhabits Senegal. Boſc.

Carabus *melanocephalus.* Winged; thorax and legs ferruginous; head and wing-caſes black. Linn. Paykull, &c.

This is *bupreſtris dorſo rubro* of Panzer, and *le bupreſte noir à corcelet rouge* of Geoffr. Found in woods of Europe, and in England. The head is black; wing-caſes deep black, and ſtriated; thorax red. Linn. Fn. Su.

Carabus *cyanocephalus.* Winged; thorax and legs ferruginous; head and wing-caſes blue. Linn. Inhabits European woods, and is found in England. Donov. Brit. Inſ.

Carabus *rufibarbis.* Winged, black; antennæ, mouth and legs rufous. Found in Germany. Smidt. Size of the preceding; body black and gloſſy; thorax ſlightly canaliculated; wing-caſes ſtriated; mandibles of the mouth black.

Carabus *lividus.* Winged, yellowiſh; head and thorax black; wing-caſes fuſcous and ſtriated. Inhabits Denmark. Lund. This inſect is of a ſmall ſize. The mouth is black; antennæ pale; thorax ſmooth, black, and without ſpots; body and legs yellowiſh.

Carabus *amethyſtinus.* Winged, azure; head and thorax ſhining-braſſy. Fabr.

Deſcribed as a native of Cayenne, from the cabinet of Von Rohr. The antennæ are hairy, brown, with ferruginous baſe; wing-caſes ſtriated; body azure.

Carabus *crux-major.* Winged; thorax orbiculate; wing-caſes black, with two rufous ſpots. Linn.—Thorax yellow, glabrous; wing-caſes behind black, with two yellow ſpots. *Carabus crux-minor.* Marſh. Ent. Brit. *Carabus crux-major.* Fabricius. Inhabits Europe. Obſ. *Carabus bipuſtulatus* of Fabricius, which that author deſcribes as an Engliſh ininſect, and refers to the cabinet of Lee, is this ſpecies.

Carabus *crux-minor.* Winged; thorax orbiculate and rufous; ſhells truncated and red, with a black croſs. Linn. *Carabus crux-major.* Marſh. Ent. Brit. *Le chevalier noir* of Geoffr. and *Bupreſtis cruciata* of Panzer. This inhabits European woods, and is, as well as the preceding ſpecies, found in England, but rarely.

Carabus *vittatus.* Winged; thorax orbiculate, and rufous; wing-caſes black, with a white ſtripe. Inhabits North America. Fabricius. Obſ. The antennæ of this are black; head rufous; ſcutel ſmall, and of the ſame colour; wing-caſes glabrous, with a longitudinal white ſtripe on a black ground; margin rufous; body ferruginous with black legs.

Carabus *turcicus.* Winged; thorax orbiculate and rufous; wing-caſes black, with a pale lunule at the baſe.

The country of this inſect, which Fabricius deſcribes from the Hunterian Collection, is unknown. The head is black; mouth and antennæ reddiſh; thorax margined, and without ſpots; wing-caſes ſtriated, ſlightly truncated, black; abdomen black; legs pale.

Carabus *hæmorrhoidalis.* Winged; thorax ſomewhat orbiculated, and rufous; wing-caſes black, and rufous at the tip. Found at Dreſden. Muſ. Romanus. The antennæ are rufous, blackiſh at the tip; head and thorax without ſpots; wing-caſes ſlightly ſtriated, and the body black.

Carabus *picipes.* Winged; thorax orbiculated, gloſſy-black; wing-caſes fuſcous, with ferruginous legs. Inhabits Sweden. Paykull.

Carabus *andreæ.* Winged; thorax orbiculated, ſhining-black; wing-caſes pale, with a black ſpot in the middle. Inhabits Italy. Dr. Allioni.

Carabus *elevatus.* Rufous; wing-caſes ſilky and pale, with a common black band. Found in France. Boſc.

Carabus *germanus.* Winged, azure; head, wing-caſes, and legs teſtaceous. Linn. Inhabits woods of Germany. Schæffer.

Carabus *velox.* Winged, blackiſh, antennæ and legs pale; wing-caſes very obtuſe. Linn. Found in ſandy places in Europe.—Obſ. The wing-caſes are ſtriated, obtuſe, and almoſt truncated.

Carabus *rufeſcens.* Winged, ferruginous, crown of the head and tail black. Fabr. An Engliſh ſpecies in the Hunterian Collection. It is of a ſmall ſize, and entirely ferruginous, except the crown and tail. *Carabus rufeſcens* of Paykull.

Carabus *præuſtus.* Winged, teſtaceous; crown of the head, tip of the wing-caſes, and the abdomen black. Inhabits Germany. Smidt. Obſ. This is of an oblong figure; the mouth and antennæ are teſtaceous; thorax rounded, ſmooth, and without ſpots; ſhells ſtriated; body teſtaceous, with black abdomen; legs teſtaceous.

Carabus *apricarius.* Black above, beneath ferruginous; wing-caſes with crenated ſtriæ. Paykull, Monogr. Inhabits the ſandy plains of Dalekarlia. Suppoſed to be the *carabus fulvus* of Geoff. and Degeer.

Carabus *lunatus.* Winged; thorax orbiculate and rufous; ſhells yellow, with three black ſpots. Fabr. *Carabus eques*, Schrank, Beytr. This inſect is found in England.

Carabus *praſinus.* Winged, black: head and thorax braſſy; wing-caſes ferruginous, with a large, common, black ſpot at the tip. Inhabits Europe. Fabr. *Carabus veridanus* of Paykull.

Carabus *curſor.* Winged; thorax braſſy-green; ſhells black, with a ferruginous ſpot at the tip. Inhabits Italy. Dr. Allioni.

Carabus *furcatus.* Livid; wing-caſes with a black abbreviated line in the middle, forked at the baſe.

This is of a ſmall ſize, and inhabits America. The head is duſky, with a black ſpot between the eyes, and the wing-caſes are ſtriated.

Carabus *diſcus.* Winged; thorax rufous; head black; wing-caſes teſtaceous, with a common dorſal fuſcous ſpot. Inhabits Germany. Smidt. Obſ. This is ſmall, and has the mouth and antennæ black; thorax rounded; wing-caſes ſtriated; legs rufous.

Carabus *meridianus.* Winged, black; anterior part of the wing-caſes and the legs teſtaceous. Linn. *Caralus meridianus,* Paykull. Inhabits ſandy places in Europe.

Carabus *vaporariorum.* Winged; thorax, anterior part of the wing-caſes, with the margin, antennæ, and legs ferruginous. Linn.

Carabus *comma.* Winged, black, with fuſcous thorax; wing-caſes grey, with a linear black ſpot. Inhabits America. Drury.

Carabus 4-*maculatus.* Winged; thorax ferruginous and glabrous; wing-caſes very obtuſe and fuſcous with two white ſpots. Linn.

Carabus 4-*guttatus.* Winged; thorax deep black; ſhells black, with two white dots on each. Deſcribed by

Fabricius as an Engliſh inſect. *Carabus 4-guttatus* of Paykull.

Carabus *uſtulatus.* Winged; thorax black; wing-caſes duſky, with two pale bands. Inhabits Europe. *Carabus dentellus*, Thunberg, and *Elophorus rupeſtris*, Fabr. Mant. &c.

Carabus *dorſalis.* Winged; thorax black; ſhells pale, with a large black dorſal ſpot. Fabr. Inhabits Germany.

Carabus *biguttatus:* Winged; thorax braſſy; wing-caſes black, with a pale ſpot at the tip. Inhabits woods of Norway.

Carabus *guttula.* Winged, deep black, with a white hyaline ſpot on the poſterior part of the wing-caſes. A native of Germany. Smidt. *Carabus riparius* of Paykull.

Carabus *teſtaceus.* Winged; head and thorax ferruginous; wing-caſes teſtaceous. Linn. Found in Europe.

Carabus *truncatus.* Winged; thorax ferruginous; wing-caſes ſtriated, abbreviated, and black. Inhabits Saxony. Hybner.

Carabus *bipunctatus.* Winged, braſſy; antennæ and legs black; ſhells with two impreſſed dots. Linn. An European ſpecies.

Carabus *abbreviatus.* Winged; thorax rufous; wing-caſes abbreviated and teſtaceous. Found among the rocks of Norway. Fabr.

Carabus *celer.* Winged, braſſy, and ſhining; legs ferruginous. Found among moſſes in Europe. Fabr.

Carabus *minutus.* Winged, black; ſhells and legs piceous. Inhabits Germany, and lives in the trunks of trees. Smidt.

Obſ. This, as the name implies, is a ſmall ſpecies. The head is black; antennæ piceous; thorax roundiſh, black, and without ſpots; wing-caſes ſtriated; body black, and legs ferruginous.

Carabus *pygmæus.* Winged; above ſhining-braſſy; beneath deep black. Inhabits Germany. Smidt.

Carabus *triſtis.* Winged, black, with rufous legs. Found in Germany. Smidt. Obſ. Small; antennæ entirely black; head and thorax glabrous and black; wing-caſes ſtriated. Paykull ſpeaks of a variety of this inſect with piceous legs, which he ſays is found in Sweden.

Carabus *truncatellus.* Winged; above duſky-braſſy; beneath deep black; wing-caſes obtuſe. Linn. Inhabits Europe. Size ſmall; antennæ and legs deep black.

Carabus *minimus.* Winged, deep black, with ſtriated ſhells. Inhabits Germany. Smidt. Obſ. This is very ſmall; head and thorax black, and without ſpots; antennæ and legs black.

### 5th Section. *Thorax various, or uncertain.*

Carabus *ruguloſus.* Apterous, thorax angulated behind, braſſy; ſhells greeniſh, fore-part ſtriated; tip and margin rugoſe. Marſh. Inhabits England.

Carabus *gibboſus.* Thorax truncated behind, and entire; ovate, convex, gibbous; wing-caſes with crenated ſtriæ; legs and antennæ piceous. Marſh. Taken near Colcheſter, by the late Mr. Curtis, on *Rubo fruticoſa.*

Carabus *rufangulus.* Thorax truncated behind, and entire, black; wing-caſes duſky; antennæ and legs ferruginous; margin of the thorax rufous. Inhabits England. Marſh.

Carabus *tibialis.* Gloſſy black; ſhanks and ſoles of the feet piceous, ferruginous. Found in England. Marſh.

Carabus *convexus.* Black; wing-caſes ſtriated; ſtriæ dotted; antennæ ferruginous; legs piceous. An Engliſh ſpecies. Marſh.

Carabus *diſcolor.* Above ſhining-azure; beneath ferruginous. A new Engliſh ſpecies. Marſh.

Carabus *immunis.* Blue-black, with teſtaceous legs. Inhabits England. Marſh.

Carabus *echinatus.* Ferruginous and hiſpid; head and thorax duſky, punctured; wing-caſes ſtriated, with a large black ſpot. Inhabits England. Marſh.

Carabus *lateralis.* Black; ſides of the thorax behind ferruginous; legs pale. A native of England. Marſh.

Carabus *punctomaculatus.* Black, ſmooth, and gloſſy; ſhells truncated, with two white ſpots. Inhabits England. Marſh.

Carabus *acutus.* Braſſy-black and very gloſſy; wing-caſes ſomewhat attenuated, and pointed; ſhanks pale. Inhabits England. Marſh.

Carabus *femoralis.* Duſky-black; wing-caſes ſomewhat truncated at the tip; thighs pale at the baſe. Inhabits England. Marſh.

Carabus *dilutus.* Pale ferruginous; eyes black; legs pale teſtaceous. Inhabits England. Marſh.

Carabus *elegantulus.* Black; antennæ ferruginous; wing-caſes and legs teſtaceous. An Engliſh ſpecies. Marſh.

Carabus *ochropus.* Piceous-black; antennæ and legs pale teſtaceous. Inhabits England. Marſh.

Carabus *rugimarginatus.* Ferruginous-black, and rather depreſſed; ſtriæ on the wing-caſes deeply punctured; margin of the thorax rough with dots. Inhabits England. Marſh.

Carabus *circulatus.* Black; antennæ, legs, and margin of the ſhells teſtaceous. Found under ſtones by the ſide of the river Uſk, near Crickhowell, Monmouthſhire. Marſh.

Carabus *purpureo-cæruleſcens.* Bluiſh-black; wing-caſes ſtriated, with numerous punctures between the ſtriæ; antennæ, feelers, and legs rufous. Found near Maldon in Eſſex. One of the new Engliſh ſpecies deſcribed by Mr. Marſham. Ent. Brit.

Carabus *nitidulus.* Bluiſh-black and gloſſy; antennæ at the baſe, ſhanks, and tarſi reddiſh; wing-caſes ſtriated with punctures. Marſh. Inhabits England.

Carabus *pulchellus.* Bluiſh-black and gloſſy; legs reddiſh; ſhells ſtriated with dots. Marſh. Inhabits England.

Carabus *ruficollis.* Black; head black and gloſſy; antennæ, thorax, and legs rufous-ferruginous. Inhabits England. Marſh.

Carabus *fulvus.* Ferruginous; legs paler; eys black. Inhabits England, and varies in having the legs more or leſs pale.

Carabus *inæqualis.* Black; antennæ and legs rufous. Inhabits England. Marſh.

Carabus *foraminuloſus.* Piceous, thorax dotted; ſhells ſtriated; legs ferruginous. Inhabits England. Marſh.

Carabus *nigriceps.* Ferruginous; head black; thorax very glabrous, and ſomewhat obcordated. Inhabits England. Marſh.

Carabus *linearis.* Ferruginous-fuſcous; wing-caſes paler, abbreviated, and truncated at the tip; legs pale. Olivier, &c. Inhabits England. Marſh.

Carabus *leproſus.* Blue; baſe of the antennæ, and legs ferruginous; ſhells brown, with two white ſpots. Inhabits Denmark. Pontopp.

Carabus *Inderienſis.* Duſky-green, beneath black; legs teſtaceous; ſhells ſtriated, the lateral margin yellowiſh-grey. Inhabits Siberia. Pallas.

Carabus *aiacer.* Apterous, black, and without ſpots;

thorax rounded behind and grooved. Inhabits the Cape of Good Hope. Thunberg.

Carabus *lunulatus*. Apterous, black; thorax lunated; wing-caſes ſtriated. Thunberg. Inhabits the Cape of Good Hope. Obſ. This is about the ſize of *Carabus violaceus*, but broader and more depreſſed.

Carabus *diſſormis*. Apterous, black; thorax tranſverſe, truncated behind; ſhells ſtriated. Thunberg. An African ſpecies, found at the Cape of Good Hope. Size of C. *hortenſis*.

Carabus *dorſalis*. Black; antennæ and wing-caſes red, with a black margin. Inhabits the Cape of Good Hope. Thunberg.

Carabus *aduſtus*. Thorax and wing-caſes fuſcous; head, antennæ, and legs red. Found at the Cape of Good Hope. Thunberg.

Carabus *afer*. Black; antennæ and legs reddiſh; wing-caſes ſmooth. Thunberg. Inhabits the Cape of Good Hope. Same ſize as *Carabus vulgaris*.

Carabus *Capenſis*. Ferruginous; thorax and ſuture of the ſhells with a longitudinal black line. Inhabits the Cape of Good Hope. Thunberg. Obſ. The body is glabrous; abdomen black or ferruginous.

Carabus *faſcialis*. Ferruginous; ſhells with a black band. Inhabits the Cape of Good Hope. Thunberg. This is very cloſely allied to *Carabus faſciatus*, and may be the ſame ſpecies.

Carabus *fimbriatus*. Apterous, black; ſides of the thorax, and margin of the wing-caſes downy white. An African ſpecies. Herbſt.

Carabus *Herbſtii*. Shells tranſverſely undulated with three rows of golden dots. Inhabits Germany.

Carabus *Pomeranus*. Coppery, beneath black; ſhells with three rows of raiſed dots, and decuſſate ſtriæ. A native of Pomerania. Herbſt.

Carabus *cylindricus*. Black, cylindrical; thorax narrowed, and grooved in the middle; ſhells with nine grooves, and dotted on the outer margin. Herbſt.

Carabus *marchicus*. Beneath black; head and thorax light grey; feelers and antennæ brown, ferruginous at the baſe. Inhabits Pruſſia. Herbſt.

Carabus *ſplendidus*. Brown; head and thorax braſſy-green; legs pale. Inhabits India. Herbſt.

Carabus *mango*. Piceous; legs ſpinulous; antennæ and margin of the thorax yellowiſh; ſhells with eight ſtriæ. Inhabits India. Herbſt.

Carabus *Friſchii*. Black; thorax with a ſingle groove, and eight furrows on the wing-caſes. Inhabits Pruſſia. Herbſt. Gmel.

Carabus *Indicus*. Black; antennæ grey at the tip; thorax with an impreſſed line; wing-caſes with ſeven grooves. Inhabits India. Herbſt.

Carabus *Mulleri*. Braſſy-black; wing-caſes ſtriated and punctured with three impreſſed dots. Inhabits Europe. Herbſt. Gmel.

Carabus *atratus*. Entirely gloſſy-black: thorax rounded; ſhells obſoletely ſtriated, with four indented dots at the ſuture. Inhabits Pruſſia. Herbſt. Gmel.

Carabus *fuſco-rufus*. Reddiſh-brown; ſhells ſtriated; thorax rounded. Inhabits Germany. Herbſt. ap. Fueſsli.

Carabus *lapideus*. Black, beneath brown; ſhells blue, with nine punctured ſtriæ, the outermoſt crenated. Inhabits Pruſſia. Herbſt. ap. Fueſsli.

Carabus *platys*. Totally black; thorax ſlightly margined; ſhells glabrous, and obſoletely ſtriated. Inhabits Pruſſia. Herbſt. ap. Fueſsli.

Carabus *virgo*. Black; antennæ and legs brown; thorax ſinuated behind; ſhells obſoletely ſtriated. Inhabits Pruſſia. Herbſt. ap. Fueſsli.

Carabus *glaber*. Gloſſy-black; ſhells brown, ſtriated; mouth, feelers, and legs piceous. Inhabits Pruſſia. Herbſt. ap. Fueſsli.

Carabus *globator*. Black; thorax hemiſpherical; ſhells ſtriated with punctures; mouth and feelers ferruginous; antennæ fulvous, and nearly moniliform at the baſe. Inhabits Pruſſia. Herbſt. ap. Fueſsli.

Carabus *lampros*. Gloſſy, very ſmooth, braſſy-black; beneath black; wing-caſes ſtriated with punctures; antennæ grey; legs brown. Inhabits Pruſſia. Herbſt. ap. Fueſsli.

Carabus *pyropus*. Gloſſy-black; margin of the thorax raiſed; antennæ and legs piceous. Inhabits Pruſſia. Herbſt. ap. Fueſsli.

Carabus *micros*. Bay-brown; ſhells ſtriated with punctures: eyes black. Inhabits Pruſſia. Herbſt. ap. Fueſsli.

Carabus *chalcos*. Braſſy; beneath black; antennæ ferruginous at the baſe; wing-caſes ſtriated with punctures. Inhabits Pruſſia. Herbſt. ap. Fueſsli.

Carabus *mixtus*. Pale yellow; head black; poſterior part of the wing-caſes ſpeckled with black. Herb. ap. Fueſsli. Inhabits Pruſſia.

Carabus *ſpinoſus*. Apterous, black; ſhells with eight grooves, and roughly dotted, poſterior part ſpinous. Inhabits the Cape of Good Hope. Voet.

Carabus *Thunbergii*. Wing-caſes teſtaceous, with a common violet ſpot; head and thorax black. Inhabits Upſal. Upſ. Tranſ.

Carabus *Upſalienſis*. Wing-caſes green, ſtriated; thorax flat, braſſy, and punctured. Inhabits Upſal. Upſ. Tranſ.

Carabus *pictus*. Depreſſed, teſtaceous; ſtriæ on the wing-caſes and the legs grey. Found by Pallas in the ſandy deſerts of Siberia, under carrion.

Carabus *didymus*. Bluiſh-black; wing-caſes yellow, with a double fuſcous ſpot. Inhabits Denmark. Müll.

Carabus *minimus*. Thorax ſomewhat black; wing-caſes ſtriated; legs and antennæ fuſcous. Inhabits Denmark, infeſts plants, and is ſcarcely larger than a flea. Müll. Fn. Fridrichſd.

Carabus *flavus*. Yellow; wing-caſes ſtriated; head, thorax, and ſpot at the tip of the wing-caſes green. Inhabits Denmark. Müll.

Carabus *feneſtratus*. Black; wing-caſes fuſcous, with oblique, yellow, ſemi-tranſparent ſpots. Inhabits Denmark. Müll.

Carabus *inflexus*. Black; ſhanks and joints of the feet piceous; wing-caſes with a flexuous ſeries of impreſſed dots. Inhabits Denmark. Müll.

Carabus *flavipes*. Black; wing-caſes braſſy; legs and antennæ fulvous. Inhabits Denmark. Müll.

Carabus *nigricans*. Black; wing-caſes, antennæ, feelers, and legs piceous. Inhabits Denmark. Müll.

Carabus *cæruleus*. Black; wing-caſes azure; antennæ, feelers, and legs fulvous. Inhabits Denmark. Müll.

Carabus *ſimilis*. Black; poſterior part of the thorax excavated at both ſides; ſtriæ of the wing-caſes ſlightly dotted. Inhabits Denmark. Müll.

Carabus *æſtivus*. Yellow; head ferruginous; thorax and wing-caſes black. Inhabits Denmark. Müll.

Carabus *flexilis*. Yellowiſh; head black; wing-caſes livid. Inhabits Scandinavia. Müll.

Carabus *lugubris*. Black, opake; antennæ and feelers fulvous; ſhanks and tarſi ferruginous. Inhabits Europe. Müll.

Carabus *pubeſcens*. Black, downy; wing-caſes ſtriated; antennæ, feelers, and legs fulvous. Inhabits Europe. Müll.

Carabus *lævis*. Braſſy; head and thorax green; wing-caſes coppery; legs piceous. Inhabits Denmark. Müll.

Carabus *vernalis*. Black; antennæ, feelers, and legs yellow; wing-caſes ſtriated with dots. Müll.

Carabus *pullus*. Black; wing-caſes ſtriated; legs piceous. Inhabits Denmark. Müll.

Carabus *aurichalceus*. Yellowiſh, above braſſy. Inhabits Denmark. Müll.

Carabus *rubicundus*. Apterous, beneath black; thorax violet; wing-caſes reddiſh, the ſuture and margin white. Lepechin. Inhabits Ruſſia.

Carabus *Forſteri*. Black; head, thorax, and ſhells gloſſy-green; antennæ and legs rufous. Inhabits America. Forſter.

Carabus *lineatus*. Thorax ferruginous; wing-caſes grey, with a common black line at the ſuture, and another in the middle; legs grey; tarſi black. Inhabits America. Forſter.

Carabus *fulvicornis*. Black; wing-caſes with ſmooth ſtriæ, the outermoſt punctured; feelers, antennæ, and legs pale yellow. Inhabits Europe. Hoppe.

Carabus *adſperſus*. Apterous; above braſſy-green, beneath black; wing-caſes with four rows of indented golden dots and raiſed lines. Inhabits Europe. Degeer. Gmelin.

Carabus *varius*. Above braſſy-black, beneath black; body ovate and ſhort; thorax convex; wing-caſes ſmooth; antennæ rufous at the baſe. Inhabits Europe. Degeer. Gmelin.

Carabus *verſicolor*. Braſſy, body ovate and ſhort, braſſy black above, beneath black; thorax convex; wing-caſes ſmooth; antennæ rufous at the baſe. Inhabits Europe. Degeer. Gmelin.

Carabus *ſubſtriatus*. Shining black; ſhells ſlightly ſtriated, with four impreſſed dots. Inhabits Europe. Degeer. Gmelin.

Carabus *Penſylvanicus*. Reddiſh-brown; head duſky; wing-caſes ſtriated; body beneath, legs, and antennæ teſtaceous. Degeer. Inhabits Europe.

Carabus *halenſis*. Black; ſhells ſtriated, and ferruginous towards the thorax; antennæ and legs teſtaceous. Inhabits Saxony. Schall.

Carabus *mærens*. Black; wing-caſes ſtriated, and thorax rough and opake. Inhabits Saxony.

Carabus *Schalleri*. Black; ſmooth; wing-caſes with very minute punctured ſtriæ.

Carabus 8-*ſtriatus*. Green, punctured; wing caſes with eight ſtriæ; legs pale. Inhabits France. Geoffr.

Carabus *nitidus*. Shining-green; wing-caſes with eight ſtriæ and three impreſſed dots; legs pale. Inhabits France. Geoffr.

Carabus *viridis*. Green; wing-caſes with eight ſtriæ, anterior part and margin fulvous. Inhabits France. Geoffr.

Carabus *nobilis*. Black; thorax deep black; wing-caſes red, with a black croſs. Inhabits France. Geoffr.

Carabus *ærugineus*. Shining; head and ſhells green; thorax coppery, with twelve dots. Inhabits France. Geoffr.

Carabus *ſtrigoſus*. Black, thorax ferruginous; wing-caſes ſtriated, with four livid ſpots. Inhabits France. Geoffr.

Carabus *nigricollis*. Entirely black; wing-caſes ſtriated, with four livid ſpots. Inhabits France. Geoffr.

Carabus 8-*maculatus*. Black, ſhells ſtriated, with eight livid ſpots. Inhabits France. Geoffr.

Carabus *minutulus*. Entirely black and ſmooth. Inhabits France. Geoffr.

Carabus *tenebrioides*. Black, thorax broad; wing-caſes ſtriated, with punctures. Inhabits France. Geoffr.

Carabus *laticollis*. Entirely green; thorax broad. Inhabits France. Geoffr.

Carabus *fuſcipes*. Black, ſmooth; legs and baſe of the antennæ ferruginous. Inhabits France. Geoffr.

Carabus *ſpinipes*. Piceous; thorax with an excavated longitudinal line; ends of the legs ſpinous. Inhabits Europe. Scopoli.

Carabus *elegans*. Thorax linear, and as long as the ſhells; legs rufous. Inhabits Europe. Scopoli.

Carabus *cordatus*. Thorax inverſely heart-ſhaped. Inhabits Europe. Scopoli.

Carabus *junceus*. Body ſomewhat linear; thorax narrowed behind. Inhabits Carniola and Helvetia. Scopoli.

Carabus *Scopoli*. Braſſy-green; wing-caſes teſtaceous, with the whole margin and band fuſcous. Inhabits Carniola. Scopoli.

Carabus *ſalicinus*. Black dotted; wing-caſes fuſcous, ſtriated; antennæ and legs ferruginous. Inhabits Carniola. Scopoli. Found on willows, &c.

Carabus *arenoſus*. Braſſy-fuſcous; thorax ſomewhat roundiſh, and dentated behind; legs rufous. Inhabits ſandy places in Carniola. Scopoli.

Carabus *lucidus*. Gloſſy-black; wing-caſes and legs teſtaceous. A ſmall ſpecies, and inhabits Hungary. Scopoli.

Carabus *atomarius*. Apterous, black, glabrous; wing-caſes edged with violaceous, ſmooth, and ſprinkled with minute, confluent, violaceous dots. Muſ. Leſk. Gmel.

Carabus *miliarius*. Apterous, black; wing caſes with elevated ſcattered dots; outer margins braſſy-violet. Inhabits Europe. Leſk. Gmel.

Carabus *fractus*. Apterous, black; wing-caſes ridged, the alternate ridges broken irregularly. Inhabits Europe. Leſk. Gmel.

Carabus *cypris*. Apterous, black, and coppery; wing-caſes with four ridges each, containing three rows of elevated dots. Inhabits Europe. Leſk. Gmel.

Carabus 5-*lineatus*. Black; thorax rounded, laterally truncated behind with an impreſſed dorſal line, and a double one on each ſide at the baſe; wing-caſes ridged, the five innermoſt joining the ſixth at the tip. Inhabits Europe. Leſk. Gmel.

Carabus *tricolor*. Ferruginous black; head, antennæ at the baſe, and thorax black; wing-caſes depreſſed, ſtriated, tip truncated, and with the outer edge of the thorax ferruginous. Inhabits Europe. Leſk. Gmel. Obſ. Antennæ cinereous and glabrous.

Carabus *confluens*. Black; thorax rounded at the ſides; wing-caſes ſtriated, the firſt and eighth, ſecond and ſeventh, united at the tip. Inhabits Europe. Leſk. Gmel.

Carabus *Leſkii*. Deep black; head and thorax black; wing-caſes brown, with ſilky ſtriæ; antennæ and legs ferruginous. Inhabits Europe. Leſk. Gmel.

Carabus *trichrous*. Black; antennæ and legs ferruginous; wing-caſes finely ſtriated; head and thorax braſſy, the latter with an impreſſed dorſal line, and two ſmaller on each ſide behind. Leſk. Gmelin makes three varieties of this ſpecies; namely, β Carabus antennis baſi rubris. Leſk. γ Carabus ater. Leſk. δ Carabus niger. Leſk. All theſe inhabit Europe.

Carabus *pullus.* Ferruginous black; wing-caſes ſtriated; antennæ rufous. Inhabits Europe. Leſk. Gmel.

Carabus *quadratus.* Thorax nearly ſquare, with an impreſſed dorſal line, and a ſmaller one on each ſide behind; wing-caſes ſtriated. Leſk. Gmel.

Carabus *plicatus.* Black; thorax ſomewhat orbicular, and plaited on each ſide behind. Inhabits Europe. Leſk. Gmel.

Carabus *picatus.* Piceous; wing-caſes black and ſtriated; thorax with an impreſſed dorſal line, and two ſmaller on each ſide behind, the inner one moſt elevated. Inhabits Europe. Leſk. Gmel.

Carabus *emarginatus.* Black; thorax nearly ſquare, and truncated behind; wing-caſes ſtriated and emarginated at the tip. Inhabits Europe. Leſk. Gmel.

Carabus *chalybeus.* Black; head and thorax braſſy; ſhells braſſy-black, and ſtriated, with greeniſh outer margin. Inhabits Europe. Leſk. Gmel.

Carabus *erythroceras.* Black; thorax nearly ſquare, and rounded at the ſides; wing-caſes ſtriated; antennæ rufous; legs ferruginous. Inhabits Europe. Leſk. Gmel.

Carabus *concolor.* Black; thorax nearly ſquare; ſhells deep black, and very finely ſtriated. Inhabits Europe. Leſk. Gmel.

Carabus *erythropus.* Black; thorax ſquare behind; wing-caſes ſtriated; antennæ and legs rufous. Inhabits Europe. Leſk. Gmelin ſpeaks of a variety of this ſpecies with ſtriæ of dots on the wing-caſes.

Carabus *crenatus.* Black; wing-caſes with crenated punctured ſtriæ. Inhabits Europe. Leſk. Gmel.

Carabus *diſtinctus.* Above black, beneath ferruginous; thorax truncated behind. Inhabits Europe. Leſk. Gmel.

Carabus *rubicornis.* Black, antennæ red; poſterior part of the thorax truncated, with an impreſſed dorſal line. Inhabits Europe. Leſk. Gmel.

Carabus *punctulus.* Black, with a row of minute dots on the ſhells. Inhabits Europe. Leſk. Gmel.

Carabus *biſpinoſus.* Black; thorax truncated behind; anterior ſhanks thick, and two-ſpined. Inhabits Europe. Leſk. Gmel.

Carabus *erythromelas.* Black, antennæ and ſhanks ferruginous. Inhabits Europe. Leſk.

Carabus *viridans.* Greeniſh-black; antennæ and legs rufous: wing-caſes ſtriated with flat finely punctured ridges. Inhabits Europe. Leſk.

Carabus *multicolor.* Black, head and thorax green; wing caſes bluiſh-green, with yellow down; mouth, baſe of the antennæ, and the legs rufous. Inhabits Europe. Leſk.

Carabus *obfuſcatus.* Fuſcous, thorax truncated behind; wing-caſes ſtriated; antennæ and legs ferruginous. Inhabits Europe. Leſk.

Carabus *dolens.* Black; wing-caſes ſtriated; ſhanks ferruginous. Inhabits Europe. Leſk.

Carabus *exciſus.* Ferruginous-glabrous; thorax truncated before and jagged behind; wing-caſes ſtriated. Inhabits Europe. Leſk.

Carabus *limbatus.* Black; thorax margined, plaited behind; wing-caſes ſtriated; legs black-ferruginous. Inhabits Europe. Leſk.

Carabus *trunculatus.* Black; thorax truncated behind; wing-caſes ſtriated; legs ferruginous-brown. Inhabits Europe. Leſk.

Carabus *chloromelas.* Black, above green; antennæ and legs ferruginous. Inhabits Europe. Leſk.

Carabus *ſinuatus.* Black; wing-caſes ſtriated, and ſinuate at the apex; antennæ rufous at the baſe. Inhabits Europe. Leſk.

Carabus *pallidicornis.* Black; wing-caſes ſtriated; thorax truncated behind, outer margin, with the legs and antennæ, pale. Inhabits Europe. Leſk.

Carabus *aurichalceus.* Braſſy-black; antennæ and legs rufous. Inhabits Europe. Leſk.

Carabus *rotundatus.* Black, above braſſy; thorax rounded; wing caſes ſtriated; ſhanks ferruginous. Inhabits Europe. Leſk.

Carabus *lituratus.* Piceous; head, legs, and ſtriated wing-caſes teſtaceous, the laſt with a common black violet ſpot at the tip; thorax violet. Inhabits Europe. Leſk.

Carabus *cylindricus.* Teſtaceous, cylindrical; head black; thorax orbicular and rufous. Inhabits Europe. Leſk.

Carabus 4-*notatus.* Black, thorax orbicular; wing-caſes blue-brown, with four teſtaceous dots; legs teſtaceous. Inhabits Europe. Leſk.

Carabus 6-*notatus.* Braſſy-black; thorax rounded; wing-caſes ſtriated, with three pair of impreſſed dots at the future. Inhabits Europe. Leſk.

Carabus *fucicornis.* Black, above braſſy; thorax rounded and punctured; wing-caſes with crenated ſtriæ; antennæ brown; legs rufous. Inhabits Europe. Leſk.

Carabus *triſpinoſus.* Black; head and orbicular thorax braſſy; wing-caſes ferruginous, braſſy, and ſtriated with punctures; legs rufous; thighs thick; ſhanks ſpinous. Inhabits Europe. Leſk.

Carabus *mæſtus.* Ferruginous; thorax rounded; wing-caſes ſtriated; head brown; antennæ and legs teſtaceous. Inhabits Europe. Leſk.

Carabus *porphyropus.* Piceous, thorax truncated; wing-caſes ſtriated; antennæ and ſhanks rufous. Inhabits Europe. Leſk.

Carabus *atratus.* Black; thorax orbicular; wing-caſes pale, varied with black; antennæ and legs ferruginous fuſcous. Inhabits Europe. Leſk.

Carabus *lepidus.* Above braſſy-green, beneath bluiſh; thorax nearly ſquare, with four impreſſed ſtriæ behind; anterior ſhanks dilated at the tip. Inhabits Luſace. Leſk.

CARAC, Karek, or Charedsi, in *Geography.* See Karek.

CARACA, in *Botany*, Rumph. Amb. 5. p. 373. tab. 132. See Dolichos *bulboſus.*

CARACAL, in *Zoology*, an animal of the lynx tribe, by ſome called the Perſian lynx. See Felis *caracal.*

CARACALLA, in *Antiquity*, a long garment, having a ſort of capuchin or hood a-top, and reaching to the heels; worn equally among the Romans by the men and the women, in the city and the camp.

Spartian and Xiphilin repreſent the emperor Caracalla as the inventor of this garment, and hence ſuppoſe the appellation *caracalla* was firſt given him. Others, with more probability, make the caracalla originally a Gallic habit, and only brought to Rome by the emperor above-mentioned, who firſt enjoined the ſoldiery to wear it. The people called it *Antoninian*, from the ſame prince, who had borrowed the name of Antoninus.

The caracalla was a ſort of caſſock, or ſurtout. Salmaſius, Scaliger, and after them Du-Cange, even take the name *caſaque* to have been formed from that of *caraque*, for *caracalla.* This is certain from St. Jerom, (epiſt. 128, ad Fabiolam,) that the caracalla which became an eccleſiaſtical garment, was a kind of cloak with a cowl; for both he, and Eucherius, (Inſtruction. l. ii. c. 10.), deſcribing the ephod, or ſacerdotal garment of the Jewiſh prieſts, tell us, it was made "in modum caracallæ," after the manner of the caracalla, or monkiſh dreſs, "ſed ſine cuculla," but without a cowl. The garment of Amphibalus, a monk of Caerleon, which St. Alban put on when he ſuffered death, is called by Bede, and other ancient writers, caracalla, which is rendered by the Saxon interpreter of Bede, a monkiſh habit. Thomas Walſingham, (apud Uſſer Britan. Eccleſ. antiq. p. 78.), relates, that this garment was preſerved in the church of Ely, in a large cheſt, which was opened in the reign of Edward II. A. D. 1314. The caracalla is deſcribed as made of ſeveral pieces cut and ſewed together, and hanging down to the feet; but it is more than probable there were ſome made ſhorter, eſpecially out of Rome, otherwiſe we do not ſee how it could have fitted the purpoſes of the ſoldiers.

Caracalla, in *Biography* and *Hiſtory*, a Roman emperor, was the ſon of the emperor Severus and Julia Domna, and born A. D. 188. At the age of eight years, his family name "Baſſianus," which he derived from his maternal grandfather, was changed by Severus, on his becoming emperor, into the highly reſpected names of Marcus Aurelius Antoninus; conferring upon him at the ſame time the dignity of Cæſar, which title was confirmed to him in the following year, viz. A.D. 197, by a decree of the ſenate. By theſe names he choſe to be diſtinguiſhed; but his infamous conduct has cauſed his hiſtory to be tranſmitted to poſterity under the nick-name of Caracalla, which was occaſioned by his fondneſs for a Gauliſh robe ſo called, (ſee the preceding article) worn by himſelf in preference to any other, and gratuitouſly diſtributed among his ſoldiers and the inhabitants of Rome, for their uſe. In his eleventh year, the emperor induced the ſoldiers, after the capture of Cteſiphon, to proclaim him "Auguſtus;" Geta his brother, receiving at the ſame time the title of Cæſar, and the name of Antoninus. The act of the ſoldiers was confirmed by the ſenate, and Severus recompenſed them with liberal donations. Before he had completed his 14th year, the emperor, whilſt he was at Antioch, proſecuting a war againſt the Jews, in which this youth had the title of commander, and for the ſucceſsful iſſue of which the ſenate decreed him a triumph, gave him the manly robe, and made him his colleague in the conſulſhip, A. D. 202. In the following year he married the daughter of Plautianus, the pretorian prefect, and an inſolent favourite, whoſe abuſe of the infamous power with which he was entruſted, brought him to an untimely end. Caracalla was inſtrumental in procuring the prefect's death, A. D. 205; and his hatred of the father was ſoon followed by an invincible diſlike of the daughter, whom he had married againſt his inclination. To the ruin of Plautianus ſucceeded that of his family; for his ſon Plautus, and daughter Plautilla, were baniſhed to the iſland of Lipari, where they languiſhed in miſery and perpetual alarms, till Caracalla, after he became emperor, ordered them to be killed. Caracalla and his brother Geta, who was declared "Auguſtus," and inveſted with the tribunitian power, A. D. 208, had conceived from their infancy an implacable hatred againſt one another. With a view of diverting their minds and allaying the animoſity that ſubſiſted between them, Severus took them with him in his expedition to Britain. But the ambition of Caracalla led him to avail himſelf of every opportunity that occurred for ingratiating himſelf with the officers and ſoldiers, and for inducing them to acknowledge him ſole emperor in prejudice to his brother, whom he regarded as an odious rival. In order to haſten his attainment of the ſovereign power, he even attempted to murder his father, whilſt he was concluding a treaty with the Britons, and receiving their arms. He afterwards intrigued with the officers and ſoldiers for the purpoſe of depoſing him. Some have ſaid, that during his laſt illneſs, Caracalla endeavoured to bribe the phyſician, who attended him, in order to haſten his death. Severus, who died at York, A. D. 211, was ſucceeded by his two ſons, whom he had inveſted with the ſovereign power during his life-time, and by his laſt will appointed to reign jointly after his death. The early antipathy that ſubſiſted between the two brothers was invincible; and the intreaties, rebukes, and exhortations, both of their father and their preceptor Antipater, had been altogether ineffectual to their reconciliation. As ſoon as Severus had expired, Caracalla endeavoured to exclude his brother, by his influence with the army, from any ſhare in the ſovereignty: but the ſoldiers proteſting that they would equally obey both the ſons of Severus, as he had appointed both to ſucceed him, he was forced to acknowledge his brother partner in the empire, and to ſuffer the ſoldiers to take the uſual oath of allegiance to each. After this ceremony, Caracalla concluded a ſhameful treaty with the Britons; and both the brothers, about the middle of ſummer, ſet out for Rome with their mother Julia, and the aſhes of their deceaſed father. In the progreſs of their journey, Caracalla attempted to murder Geta; and this attempt increaſed their mutual animoſity and jealouſy to ſuch a degree, that they afterwards marched with their ſeparate guards, and with no leſs warineſs than if they had been in an enemy's country; lodging conſtantly in different houſes, and carefully watching the motions of each other. On their arrival at Rome, they were received with great ſolemnity: but the diſcord that prevailed, and that was every day increaſing between the two princes, produced two contending factions; and it was therefore propoſed to make a diviſion of the empire between them. Geta, who loved a quiet life, conſented, that if Caracalla would ſurrender Aſia and Egypt, he would retire to Alexandria, or Antioch, and leave him in unmoleſted poſſeſſion of the reſt of the empire. But this ſcheme was defeated by their mother Julia. Towards the cloſe of this year, Caracalla made another attempt to murder his brother during the feaſt of Saturn; and this outrage occaſioned almoſt an open war between the two princes, and a great deal of bloodſhed. In the following year, A. D. 212, he effected his purpoſe, on occaſion of an interview which was propoſed, with a view to their reconciliation; when ſome centurions whom he had placed in ambuſh ruſhing on Geta with their ſwords in their hands, and urged on by the monſter Caracalla himſelf, diſpatched him with many wounds, whilſt he was ſeeking refuge in the arms of his mother, who in endeavouring to ſave him was herſelf alſo wounded. Having by this atrocious act made himſelf ſole maſter of the empire, he conciliated the attachment of the army by the moſt extravagant donations, and by circulating reports, as well as by public declarations, that his brother was a traitor, and that he had ſlain him unwillingly in his own defence, he eſtabliſhed his own power. In order to delude the ſoldiers and the people, and to gain credit to theſe unfounded pretences, he repaired to the camp of the prætorian cohorts, and proſtrating himſelf upon the ground before the images of the tutelary deities, he offered up ſacrifices of thankſgiving for his happy eſcape: juſtifying himſelf alſo by ſimilar declarations to the ſenate, before which he appeared, ſurrounded with his guards, and armed with a cuiraſs, he obtained the approbation of that baſe and venal aſſembly. By artifices of this nature he ſucceeded in prevailing with the prætorians to declare him ſole emperor, and Geta a public enemy. That Caracalla himſelf was active as one of the executioners in the

the aſſaſſination of his brother is not improbable, if we conſider, that ſome years after this event, he conſecrated in the temple of Serapis, at Alexandria, the ſword which he had uſed in the murder of Geta. When the ſavage deed was perpetrated, he forbade his mother, by menaces againſt her life, even exhibiting any ſigns of ſorrow on the occaſion: and he actually put to death Fadilla, the only remaining daughter of Marcus Aurelius, for diſobeying a ſimilar injunction.

In order to conciliate the ſenate, he made an oſtentation of clemency, by allowing all exiles to return to the city; and as he made no diſtinction between the innocent and the guilty, he thus filled Rome with multitudes of villains who had richly deſerved the puniſhment inflicted on them. With a view of ſatisfying the public, Caracalla permitted the memory of his brother to be honoured, uſing at the ſame time this memorable expreſſion, "Sit divus, dum not ſit vivus," i. e. "Let him be a god, as long as he is not alive;" and accordingly the ſenate iſſued a decree, by which he was enrolled among the gods. Notwithſtanding theſe apparent but undiſtinguiſhing tokens of clemency, and this ſeeming reſpect for his deceaſed brother, Caracalla was rigorous and cruel in his conduct towards all thoſe who manifeſted any reſpect for Geta, or who had any connection with him whilſt he lived; and he adopted every method which he could deviſe for eraſing the remembrance of him from the minds of ſurvivors. Dion Caſſius informs us, that in the general maſſacres of his partiſans and friends, he ordered all his domeſtics, to the number of 20,000 perſons, to be inhumanly put to death; it was death even to mention his name; and no one was allowed to uſe it even on the ſtage, where it was familiarly applied to ſlaves. All the money that bore his name was ordered to be melted down; and the inſcriptions were eraſed. The dead bodies of thoſe who were maſſacred were treated with indignity, burnt without ceremony, or were expoſed to the beaſts and birds of prey. Not ſatisfied with the murder of perſons of inferior rank, Caracalla ſacrificed to his rage and jealouſy a great number of illuſtrious victims, among whom, Papinianus, the prætorian præfect, and the moſt eminent civilian in the opinion of Zoſimus and Cujas, that ever lived, was the moſt diſtinguiſhed. Papinianus had returned the confidence of Severus by faithful and zealous endeavours to promote union and concord between the two brothers; and having thus diſguſted Caracalla, he was deprived of the poſt of prætorian prefect. But the immediate cauſe of his death was his laudable refuſal to concur in furniſhing Caracalla with apologies for the murder of his brother. "It is eaſier," he nobly replied, "to commit a parricide, than to juſtify it; and to accuſe an innocent perſon is a ſecond parricide." In ſhort, no ſex, rank, or age, eſcaped the cruelty of this monſter of wickedneſs: and he ſeems to have equalled, or even exceeded Caligula in the indulgence of the moſt malignant paſſions. Indeed, in another reſpect he alſo reſembled him, as a portion of real inſanity ſeems to have blended itſelf with a temper and character radically and habitually vicious. His acts of rapine and extortion correſponded to thoſe of his cruelty; and he ſeems to have made it his ſtudy through his whole reign to haraſs and oppreſs his people. Fond of public ſpectacles, he ſquandered with profuſion in the ſupport of theſe, what he extorted from the people; and his prodigality to the ſoldiers, with a view of engaging their affections, was unbounded. In games and ſhows he himſelf took an active part, fighting on occaſions of this kind with wild beaſts, and driving chariots in the circus. Whilſt he indulged a taſte altogether unſuitable to his high rank and office, and the meaneſt kind of curioſity and inquiſitiveneſs, he deſpiſed every quality that was likely to command eſteem; and his ignorance, and his contempt of literature and of learned men, were notorious. His debaucheries were as deteſtable as his other bad qualities; and yet, with an unpardonable hypocriſy, he affected zeal for chaſtity and even for religion, though he forbade any one's calling him by the names of the divinities he worſhipped: but his pretended piety was blended with a paſſion for the deluſive arts of magic and judicial aſtrology.

Having eſtabliſhed in the capital of his empire a character deteſtable for cruelty and oppreſſion, and levelled the prerogatives of the Roman people by extending them to all the ſubjects of his empire, he determined to trace the footſteps of Alexander the Great, for whom he profeſſed an extravagant veneration, in the path of military glory. Ambitious of reſembling this conqueror in every circumſtance of his hiſtory, he condeſcended to aſſociate upon the moſt intimate terms with his ſoldiers, and to take part with them in all their military labours and exerciſes; and having thus fitted himſelf, as he conceived, for all the offices of a great commander, he left Italy, A. D. 213, and commenced his expeditions by viſiting Gaul, where he exerciſed ſuch cruelties that he was more hated and abhorred there than he had ever been at Rome. He afterwards croſſed the Rhine, and conducted an expedition againſt the Catti and the Alemanni, now firſt mentioned in hiſtory; but he was obliged to purchaſe a peace with large ſums, and the liberty of returning with ſafety into the Roman dominions. As ſoon as it was known in Germany that he had bought a peace of theſe people, all the nations inhabiting that extenſive country flew to arms, and compelled him to grant them yearly penſions, the ſupply of which reduced him to the neceſſity of coining falſe money. In an interview with the Barbarians on this occaſion, he was guilty of an act of perfidy, which of itſelf is ſufficient to fix an indelible ſtain on his memory. Having ordered all the youth of Noricum to take arms, and join him, he commanded his troops to fall upon them and to put them all to the ſword. For this pretended victory he aſſumed the title of "Alemannicus." From the borders of the Rhine he marched to the Lower Danube, and obtained ſome ſlight advantages over the Barbarians, then hardly known, but afterwards too intimately connected with the affairs of declining Rome, called by the Romans Geti, and in ſubſequent times Goths. Having made an alliance with the Dacians, he paſſed from the banks of the Danube into Thrace; and afterwards croſſing the Helleſpont, he arrived at Ilium, and paid ſingular honours to the memory of Achilles at his ſuppoſed tomb. The death of Feſtus, his favourite freedman, whom he is ſuppoſed to have poiſoned, for the purpoſe which he propoſed, furniſhed him with an opportunity of reſembling Achilles in his funeral of Patroclus. Accordingly, he ſpared no expence in rendering the obſequies of Feſtus extremely pompous. From Ilium he went to Pergamus, to ſeek relief in the temple of Æſculapius, under the diſorders of mind and body, of which he had reaſon to complain, and which were probably owing to the agitations of remorſe and terror. Having ſpent the winter at Nicomedia, he prepared for attacking the Parthians and Armenians; but Artabanus was under a neceſſity, on account of the inteſtine diviſions of Parthia, to avert the attack by a timely ſubmiſſion. By the baſeſt perfidy, he made captives of Abgarus, king of Edeſſa, and the king of Armenia; but the only fruit which Caracalla reaped from his perfidy was the defeat of Theocritus, one of his generals, the conſequent ſhame he ſo juſtly merited, and the univerſal diſtruſt of all mankind. However, he poſſeſſed a ſoul incapable of feeling ſuch humiliations; and therefore gloried in the ſucceſs of his exploits, and wrote haughty and boaſtful letters to the ſenate on the occaſion, as Caligula had done before him. At Alexandria, whither he next went, he perfidiouſly availed himſelf of an opportunity that offered itſelf of avenging himſelf of the Alexandrians for ſome railleries which theſe volatile and ſarcaſtic people had formerly thrown out againſt him. The meaſure he adopted for this purpoſe was the moſt horrible maſſacre which hiſtory records. Having declared his intention of rendering perſonal homage to the god Serapis, the Alexandrians received him with every poſſible token of reſpect. Upon his firſt entrance into the ſacred temple, he ſacrificed whole hecatombs, and burnt upon the altar a great quantity of incenſe. From thence he proceeded to the tomb of Alexander, and rendered peculiar honours to the deceaſed hero. All theſe ſpecious and pompous appearances ſerved, however, to conceal his black deſign of extirpating the inhabitants of Alexandria. In the midſt of the feſtivities produced by the deluſion he was practiſing, he directed, from his poſt in the temple of Serapis, his troops to fall on the aſſembled inhabitants and to make an undiſtinguiſhed ſlaughter. Many thouſands of natives and ſtrangers fell in the carnage, and an univerſal pillage ſucceeded, which, with the ſeverities that followed this horrid maſſacre, reduced their flouriſhing capital almoſt to a ſtate of deſolation. This deſolation, however, was but a temporary evil; for Caracalla not long ſurviving, Alexandria recovered its ſplendour by its own reſources, and ſoon became again the ſecond city of the empire. Caracalla having completed his purpoſes of vengeance at Alexandria, determined to proceed towards Parthia; and making Artabanus's refuſal to give him his daughter in marriage a pretext for violating the peace which had been concluded between the empires, he ravaged a large tract of country, plundered the cities, and after overrunning all Media, drew near the royal capital, where, like a daſtardly enemy, he vented his fury even upon the dead, opening the tombs of the Arſacidæ, and ſcattering their aſhes to the wind. Upon his return to Meſopotamia he boaſted that he had conquered the Parthians, whom he had not even ſeen, and in his letters to the ſenate and Roman people, he pretended that he had ſubdued all the Eaſt, and obliged every country beyond the Euphrates to acknowledge their laws. In conſequence of theſe pretences, he obtained from the ſenate the appellation of "Parthicus," and a decree for a triumph. The war would have been furiouſly renewed if a domeſtic conſpiracy had not put an end to the miſeries inflicted on the world by this deteſtable tyrant. M. Opilius Macrinus had riſen from a low ſtation to the poſt of prætorian prefect; but he had incurred the jealouſy and hatred of Caracalla, whoſe ſuſpicion was increaſed by the prediction of a diviner, that he was to ſucceed him on the throne. The circumſtances of Macrinus were become critical, in conſequence of ſome diſpatches from Rome, which accidentally fell into his hands; and in order to evade the ſtroke which was meditated againſt him, he employed a diſcontented centurion, named Martialis, to aſſaſſinate the empe- . Accordingly, whilſt he was purſuing his journey from ſſa, where he had wintered, to Carrhæ, for the purpoſe fering a ſacrifice in the temple of the Moon, a call of nature obliged him to alight: Martialis ſeized the opportu- when he was almoſt alone, to diſpatch him with a The aſſaſſin inſtantly fled; but he was purſued, en, and ſlain by ſome of the emperor's attendants. ſhed Caracalla on the 8th of April, A.D. 217, at 29 years, and after a reign of ſix years, two ſix days. His death was regretted by the ſol emanded that he ſhould be ranked among the ceſſor Macrinus treated as a god, a prince whom he had been inſtrumental in killing; and the ſenate, by his orders, decreed him divine honours. Thus, this monſter, deteſted by heaven and earth, had his temple, his prieſts, and feſtivals, eſtabliſhed for the worſhip of him at Rome. The authors who lived under Caracalla were Q. Severus Sammonicus, murdered by his order; Ælius Maurus, and Oppian. The principal hiſtorians of this period are Herodian, Dion Caſſius, and Spartian. Crevier's Hiſt. of the Emperors, vol. viii. Anc. Un. Hiſt. vol. xiii.

CARACARA, in *Ornithology*, the name under which Buffon deſcribes the Braſilian kite. See Falco *Braſilienſis*. The ſame name caracara has been alſo given to the goldbreaſted trumpeter, Psophia *Crepitans*, which ſee.

CARACARAS, in *Zoology*, a ſpecies of ſnake. See Coluber.

CARRACCA, La, in *Geography*, a ſea-port town of Spain, in the province of Andaluſia; two leagues E. of Cadiz.

CARACCAS, a diſtrict of Terra Firma in South America, belonging to the Spaniards. It lies between the province of Venezuela to the weſt, and that of Cumana to the eaſt, and is bounded on the north by the Caribbean ſea, and on the ſouth, by parts of America little known. The coaſt is rocky and mountainous, but its vallies and plains are fertile, and produce the cacao-tree, indigo, ſugar, and tobacco. The air is reckoned clear, and the climate wholeſome. Its principal towns are Caraccas, the capital, and Porto Cavallo, which is a ſea-port town. In conſequence of the acknowledged ſuperiority of the cacao nuts in this province, and its communication with the Atlantic which facilitates the conveyance to Europe, the culture of the cacao there is more extenſive than in any diſtrict of America. However, the Dutch, by the vicinity of their ſettlements in the ſmall iſlands of Curaçoa and Buen-Ayre, to the coaſt of Caraccas, gradually ingroſſed the greateſt part of the cacao-trade. Hence the traffic with the mother country ceaſed almoſt entirely; and ſuch was the ſupine negligence of the Spaniards, or ſuch were the defects of their commercial arrangements, that they were obliged to receive from the hands of foreigners this production of their own colonies, at an exorbitant price. In order to remedy an evil no leſs diſgraceful, than pernicious to his ſubjects, Philip V. in 1728, granted to a body of merchants an excluſive right to the commerce with Caraccas and Cumana, on condition of their employing at their own expence, a ſufficient number of armed veſſels to clear the coaſt of interlopers. This ſociety, ſometimes diſtinguiſhed by the name of the company of Guipuſcoa, from the province of Spain in which it was eſtabliſhed, and ſometimes by that of the company of Caraccas, from the diſtrict of America to which it trades, has carried on its operations with ſuch vigour and ſucceſs, that Spain has recovered an important branch of commerce, which ſhe had ſuffered to be wreſted from her, and is plentifully ſupplied with an article of extenſive conſumption at a moderate price. From this inſtitution the colony, as well as the parent ſtate, has derived great advantage. The planters in the Caraccas are not left to depend entirely on the company either for the importation of European commodities, or the ſale of their own productions. The inhabitants of the Canary iſlands have the privilege of ſending thither annually a regiſter ſhip of conſiderable burden; and from Vera Cruz in New Spain, a free trade is permitted to every port comprehended in the charter of the company. Hence ariſes a competition which tends to fix the price of all commodities, both purchaſed and ſold, at its natural and equitable rate. The company has not the power of raiſing the former or degrading the latter at pleaſure; and accordingly, ſince it was eſtabliſhed, the increaſe of culture, of population, and of live ſtock, in the province of Caraccas, has been very conſiderable. During twenty years, prior to the eſtabliſhment of this company, only five ſhips ſailed from Spain to that province; and during 16 years, from 1706 to 1722, not a ſingle ſhip arrived from Caraccas in Spain. Before the erection of the company, neither tobacco nor hides were imported from Caraccas into Spain. But ſince the commercial operations of the company began, in the year 1731, the importation of cacao into Spain has very much increaſed. The company at firſt employed twelve veſſels to carry on its trade, with nineteen to guard the coaſt from ſmugglers, varying theſe numbers as ſuited their convenience, and for both theſe purpoſes they engaged 2500 ſeamen. The ports they uſed in Spain were St. Sebaſtian and Cadiz. During thirty years ſubſequent to 1701, the number of "fanegas" (each 110 pounds) imported from Caraccas was 643,215. During eighteen years ſubſequent to 1731 the number of fanegas imported was 869,214. And if we ſuppoſe the importation to be continued in the ſame proportion during the remainder of 30 years, it will amount to 1,448.746 fanegas, which is an increaſe of 805,531 fanegas. During eight years ſubſequent to 1756, there have been imported into Spain by the company 88,482 "arrobas" (each 25 pounds) of tobacco and hides to the number of 177,354. During five years ſubſequent to 1769, it has imported 179,156 fanegas of cacao into Spain, 36,208 arrobas of tobacco, 75,496 hides, and 221,432 peſos in ſpecie. In return for the cacao with which it ſupplies Mexico, it receives caſh, which is either remitted to Spain or laid out in purchaſing European goods. The quantity of cacao raiſed in the province is double of that which it yielded in 1731; the number of its live ſtock is more than treble, and its inhahitants much augmented. The revenue of the biſhop, which ariſes wholly from tythes, has increaſed from 8000 to 20,000 peſos; the price of cacao has decreaſed from 80 peſos for the fanega to 40. Guiana, including all the extenſive provinces ſituate on the banks of the Orinoco, the iſlands of Trinidad and Marguerita, are added to the countries with which the company of Caraccas had liberty of trade by their former charters; and in 1752 their grant was extended to the province of Maxacaybo. However, in many of the operations of this company, the illiberal and oppreſſive ſpirit of monopoly has been conſpicuous, and has prevented the company from deriving all the beneficial effects, which their conſtitution was adapted to afford them. In 1780 this company received a very ſevere ſtroke in the capture of a rich convoy by Lord Rodney, valued at more than 20,000l. and a few years after their capital was abſorbed in a new eſtabliſhment, called the *Company of the Philippines*; which ſee. Robertſon's America, vol. iii. Townſend's Journey through Spain, vol. ii.

CARACCAS, or LEON DE CARACCAS, the capital of the diſtrict above deſcribed, ſituated in a plain ſome leagues from the ſea, from which it is ſeparated by mountains, and rendered difficult of acceſs: and containing about 24,000 inhabitants. It is the reſidence of a governor, and carries on a conſiderable trade. Its port, named "Guayra," though it has bad anchorage, is improved by the conſtruction of a mole. N. lat. 10° 30′. W. long. 66° 26′.

CARACCAS, *Silla de*, a mountain on the coaſt of South America, in the province of Venezuela, 1316 toiſes in height. There is a dreadful perpendicular precipice of 1300 toiſes in this mountain, above Caravalledo; the northern part of this chain being perhaps broken by the gulf of Mexico.

CARACCI, LUDOVICO, in *Biography*, an eminent painter of hiſtory, landſcape, and portrait, was born at Bologna in 1555, became a diſciple of Proſpero Fontana, and acquired his diſtinguiſhed reputation by ſtudying the works of Titian, Tintoretto, and Paolo Veroneſe, at Venice, and of Parmigiano and Corregio at Parma. With leſs fire in his compoſitions than Annibal or Agoſtino, he ſurpaſſed them in grace, dignity, and ſweetneſs; and particularly in religious ſubjects he excelled them both. "Simplicity and elegance diſtinguiſhed all his deſigns; his touch was lively, his expreſſion good; the hairs of his heads are graceful; his figures are marked with a fine outline; and his compoſition is often ſublime." "He was," ſays Mr. Fuſeli, "the ſworn pupil of nature." "To a modeſt, but dignified deſign, to a ſimplicity eminently fitted for thoſe ſubjects of religious gravity which his taſte preferred, he joined that ſolemnity of hue, that ſober twilight, that air of cloiſtered meditation, which has been ſo often recommended as the proper tone of hiſtoric colour." Whenever he courted elegance, which was ſeldom the caſe, he did it with enviable ſucceſs. His maſter-piece in oil is the altar-piece of John the Baptiſt, now in the Louvre. This artiſt died in 1619. Pilkington.

CARACCI, *Agoſtino*, the elder brother of Annibal and the diſciple of Ludovico, was born at Bologna in 1558; and having firſt ſtudied his art in the ſchool of Proſpero Fontana, he afterwards became the diſciple of Paſſeroti, but he laid the foundation of his eminence under the direction of his kinſman Ludovico. He aſſiſted Annibal in the Farneſian gallery, but leſs aſſiduous than his brother, he devoted much time to engraving, which he had learned from Cornelius Cors. "He combined," ſays Mr. Fuſeli, "with ſome learning, a cultivated taſte, correctneſs, and ſometimes elegance of form, and a corregieſque colour, eſpecially in freſco." The moſt celebrated picture of this maſter is the communion of St. Jerom, now at the Louvre, which has been often compared with its rival picture of the ſame ſubject by Domenichino. "Theſe two pictures," ſays Mr. Fuſeli, "have often been compared without much diſcrimination of the principles that diſtinguiſh either, and the reſult has commonly been in favour of Domenichino; but ſurely, if Agoſtino yields to his ſcholar in repoſe, and the placid economy of the whole, he far excels him in the principal figure, the expreſſion and character of the ſaint." Agoſtino died in 1602. Pilkington.

CARACCI, *Annibal*, an eminent painter of hiſtory, portrait, and landſcape, was born at Bologna in 1560, and being a diſciple of his couſin-german, Ludovico Carracci, he imbibed from him the beſt principles of his art, as well as an ambition to arrive at perfection in the exerciſe of it. With this view he ſtudied the works of Titian, Tintoretto, and Paolo Veroneſe, at Venice, and thoſe of Corregio at Parma. At an early age he manifeſted proofs of an extenſive genius, which not only ſurpriſed the artiſts of his time, but excited a general expectation of the excellence to which he attained. The fame of the Carraccis having reached to Rome, Annibal was invited thither by the cardinal Farneſe, and employed in painting the gallery which bears his name. But though he laboured ten years at this work, the avaricious eccleſiaſtic preſented him with only 500 crowns. At Rome he had an opportunity of obſerving the antique ſtatues, the baſſo-relievos, and alſo the compoſitions of Raphael, and he was thus led to abandon his Bologneſe manner, formed after that of Corregio, and to adopt another more learned, but more dry and leſs natural, both in deſign and in colouring. There is a ſameneſs in the manner of all the Caraccis; and the only difference between them is that which reſults from their diverſity of temper and diſpoſition. Annibal had more fire, boldneſs, and ſingularity of thought than the two others;

and his deſigns were more profound, his expreſſion more lively, and his execution more firm. His genius was better adapted to poetical and profane, than to ſacred ſubjects; though, when he attempted the latter, he generally ſucceeded. His talents were admirably formed for landſcape: the forms of his trees are grand; and in repreſenting objects after nature, he gave them a character that diſtinguiſhes them ſtrongly. He is ſaid to have been deficient, however, in his knowledge of the principles of the chiaro, nor are all his local colours commendable: but upon the whole, no painter ſeems to have been more univerſal, more eaſy, more certain in every thing he did, nor more generally approved than Annibal. "Annibal," ſays Mr. Fuſeli, "though ſuperior to his couſin and brother in power of execution and academic proweſs, was inferior to them in taſte, ſenſibility, and judgment; in proof of which he adduces the maſter-work of Annibal, viz. the Farneſe gallery; "a work whoſe uniform vigour of execution nothing can equal but its imbecility and incongruity of conception; if impropriety of ornament were fixed by definition, the ſubjects of that gallery might be quoted as the moſt deciſive inſtances; the man of ſenſe may admire the ſplendour, the exuberance, the concentration of powers diſplayed by Annibal de Caracci, but the man of ſenſe muſt lament their miſapplication in the Farneſe gallery." He died in 1609. Pilkington.

The three Carraccis, of each of whom we have above given a brief account, laid the foundation of that ſchool which has been highly celebrated by the title of the academy of the Caraccis. Young men, who aſpired to be great maſters, reſorted hither for inſtruction; and they were furniſhed with well choſen models of men and women, fine caſts from the beſt figures, from antique ſtatues, and curious baſſo-relievos; as well as the moſt capital deſigns of the great maſters, the moſt inſtructive books pertaining to the art, and the leſſons of a very noted anatomiſt, who taught whatever it was neceſſary to know, concerning the knitting of the bones, and the inſertion of the muſcles.

Among the number of the excellent artiſts that were formed in this academy, were Guido, Domenichino, Albano, Lanfranc, Guercino, and many others. Pilkington.

CARACCIOLI, Robert, a famous preacher, was born in 1425 of a noble family at Lecce in the kingdom of Naples. In early life he entered into the order of Minor Obſervantines, and before his 30th year he acquired ſuch reputation for pulpit eloquence, that Pope Nicholas V. diſpenſed with his obedience to his ſuperior, and allowed him to diſpoſe of himſelf at pleaſure. Hence it has been ſaid that he was leſs famous for ſanctity of manners than for eloquence. After having been employed in ſeveral honourable commiſſions by the popes Calixtus III. and Sixtus IV. he became firſt biſhop of Aquino, and afterwards of Lecce, where he died in 1495. As a preacher he was highly admired, and regarded as a model, with reſpect to tone, geſture, and manner, to all the young orators of his time. His ſermons, which were adapted to a rude age, and which poſſeſs few graces of ſtyle, have been collected at different times; but moſt of them are contained in an edition at Venice, 3 vols. 1490, and at Lyons in 1503. Tiraboſchi.

CARACHABAN, in *Geography*, a town of Perſia, in the province of Adirbeitzan; 80 miles W. of Tauris.

CARACO, in *Zoology*, an animal of the rat kind, nearly allied to the Great or Norway rat, deſcribed by Dr. Pallas as a native of Siberia. See Mus *caraco*.

CARACOL, in *Architecture*, is ſometimes uſed for a ſtair-caſe in the form of a helix or ſpiral.

Caracol, in *Geography*, a town of South America, between Guayaquil and Quito.

Caracol, in the *Manege*, a motion which a cavalier makes half round; or a half-turn from left to right; changing hands: that his enemy may be uncertain on which ſide he intends to attack; whether in front or flank. The word comes from the Arabic *garagol*, and that from the Hebrew *carac*, *involvere:* but we have it immediately from the Spaniſh, where caracol ſignifies properly a *ſnail*, and figuratively the evolution deſcribed above.

Caracol, in *Military Language*, is the half-turn each horſeman in an army makes after his diſcharge, to paſs from the front of the ſquadron to the rear.

Caracol is alſo a ſort of half wheel, or ſemicircular movement not only by one horſeman, but by a whole troop of cavalry, by means of which they perform a ſort of winding, or ſerpentine motion, alternately on their right and on their left, in advancing towards the enemy. The object of this movement, or of the *caracol*, is to diſquiet or annoy the enemy, to throw him into diſorder or confuſion, to conceal from him your intended point of attack, to induce him to divide or break, by diſtracting his attention, and to ſeize the favourable moment of falling upon him with advantage. The light horſe are peculiarly calculated for this kind of manœuvre and attack. Velocity, indeed, is the principal excellence and very life of cavalry.

CARACOLI, in *Commerce*, a factitious metal whereof the natives of the Caribbee iſlands make a kind of ornament, in form of a half-moon, which is called by the ſame name. The metal is brought from the Terra Firma; and the common opinion is, that it is compoſed of gold, ſilver, and copper; but the mixture is ſo perfect, that a metal reſults from the whole which never ruſts nor tarniſhes, how long ſoever kept, either in the ſea or the ground. The Engliſh and French goldſmiths have made frequent attempts to imitate it. Thoſe who have ſucceeded beſt, uſe ſix parts of ſilver, three of purified copper, and one of gold. But the curious find all the imitations much inferior in beauty to the original metal of the ſavages.

M. Hauterire, procurator-general of Martinico, makes the caracoli to be a compound of gold only with a ſort of copper found in the Terra Firma of America. F. Labat takes it for a native, or ſimple metal. The Americans alſo make rings, buckles, cane-heads, and the like, of caracoli.

CARACOMBO, in *Geography*, an African iſland, ſituated about 15 miles N. of the line, at a ſhort diſtance N.W. of the iſland of St. Thomas, and a little above the mouth of the river Gabon. It produces a variety of fruits and plants peculiar to itſelf, beſides birds and animals. It is not uncommon to find a hundred neſts of birds floating on the water upon one branch of a tree, or a ſlender twig, thus guarding themſelves againſt the attacks of ſerpents and lizards. The iſland is inhabited, as it is ſaid, by an abandoned, profligate race both of men and women. The latter in particular are ſo lewd that they are ſaid to proſtitute themſelves without diſcrimination and without ſhame.

CARACORES, in *Sea Language*, denote light veſſels uſed by the natives of Borneo, and the adjacent iſlands, and alſo by the Dutch as guarda-coſtas in thoſe latitudes. They are high at each end, and chiefly navigated with paddles, in the uſe of which they ſit both within and without board, on narrow platforms of reeds, ſupported by bars rigged out acroſs the veſſel, and one at the outer end on each ſide, which ſerve as balances to prevent its being upſet. By placing three or four ranks of rowers on the platform of reeds outſide, and ſome within, they can multiply their number ſo as to proceed with great velocity. They have triple ſheets of bamboo for a maſt, ſupported by ſhrouds, on which is hoiſted an oblong ſail, bent to a ſort of bamboo yard at the head, and a boom at the foot. The ſail is hauled aft by a ſheet, the yard has a bowline to keep to windward, and a brace or vang that leads aft. The ſail rolls up or furls by a winch at the end of the boom. See *Plate of* Boats.

CARACORUM, or Holin, in *Geography*, a Tartar village, the poſition of which is marked, in the map of M. D'Anville and the Chineſe Itineraries, about 600 miles to the north-weſt of Pekin. This village was gradually ennobled by the election and reſidence of the ſons and grandſons of Zingis. It contained two ſtreets, the one of Chineſe mechanics, the other of Mahometan traders; and the places of religious worſhip, one Neſtorian church, two moſques, and twelve temples of various idols, repreſent in ſome degree the number and diviſion of inhabitants. However, a French miſſionary declares, that the town of St. Denys, near Paris, was more conſiderable than the Tartar capital, and that the whole palace of Mangou was ſcarcely equal to a tenth part of that Benedictine abbey.

CARACT, or Carat, in *Commerce*, a denomination given to an imaginary weight, which expreſſes the degree of goodneſs, fineneſs, and perfection, or imperfection of gold. The whole maſs is conceived to be divided into twenty-four equal parts, i. e. twenty-four carats; and the purity of the ſpecimen is expreſſed by the number of carats of pure gold it contains. Thus gold of eighteen carats fine means a compound of $\frac{18}{24}$ths of pure gold, and $\frac{6}{24}$ths of ſome other metal: gold of twenty-two carats fine contains $\frac{22}{24}$ths of pure gold, and $\frac{2}{24}$ths of alloy; and pure gold is called gold of twenty-four carats fine.

The word is alſo written *carract*, *carrat*, *karract*, and *karrat*. Its original is conteſted: but we chooſe to follow Kennet, who derives it from *carecta*, a term which this author obſerves anciently denoted any weight, and came not till of later days to be appropriated to that which expreſſes the fineneſs of gold, and the gravity of diamonds. Others, however, derive it from the Arabic "kirat," which weighed half of a "danek," or grain; of which ſix made up the "dirhem," or Arabic drachm; ſo that twelve "kirats" were equal to a "dirhem." See the next article.

The mint-men fix the higheſt purity and perfection of gold at twenty-four carats; and the ſeveral degrees are eſtimated from the diviſions hereof, which are called *grains*: but it is to be obſerved, that what care ſoever is taken in purifying gold, to clear it from droſs, it can never be brought to twenty-four carats; but ſtill comes ſhort, at leaſt $\frac{1}{4}$ of a carat, or a grain; this grain they call a ſixteenth; and this ſixteenth they ſubdivide into two eighths; and each of thoſe eighths into two ſixteenths: on which calculation, they ſay, gold may be purified as far as the firſt ſixteenth of the ſecond eighth, but no further. Gold of twenty-two carats, is that which has twenty-two parts of fine gold, and two of ſilver, or other metal; or that which, in refining, loſes two parts in twenty-four of its weight. The goldſmiths generally work in gold of twenty-two carats; that being the ſtandard gold of this kingdom. By the laws of France they are prohibited from working in gold below twenty-three carats. In England, the carat is divided into four grains; in Germany, into twelve parts; and in France, into thirty two. The Chineſe reckon by touches, a hundred of which correſpond to our twenty-four carats. *Carat fine*, as above, is the twenty-fourth part of the goodneſs of a piece of pure gold. *Carat price* is the twenty-fourth part of the value of an ounce or mark of gold.—They alſo ſometimes ſay, the *carat weight*, which is the twenty-fourth part of the weight of the ounce or mark. Two troy grains make a carat grain.

Caract is alſo the weight uſed in weighing diamonds, pearls, and precious ſtones; where it conſiſts of four grains. In this ſenſe, the word is by ſome ſuppoſed to be derived from κερατιον, a fruit which the Latins call *ſiliqua*, and we *carob bean*; each of which may weigh about four grains of wheat: whence the Latin *ſiliqua* has alſo been uſed for a weight of four grains. Bruce, (Appendix to his Travels in Abyſſinia, p. 66.) deduces it from the name of the bean of the Kuara-tree, which is called "Carat." From the gold country in Africa it paſſed, as he ſuppoſes, to India; and there came to be the weight of precious ſtones, eſpecially diamonds.

The carat by which jewellers eſtimate the weight of diamonds and pearls, is about $\frac{1}{150}$ of a troy ounce. Jeffreys on Diamonds.

Hence the carat is about $3\frac{1}{5}$ grains troy.

Carats are divided into halves, quarters, or grains; and farther, into eighths, ſixteenths, and thirty-two parts. Id. ibid.

CARACTACUS, in *Biography* and *Britiſh Hiſtory*, one of the moſt renowned of the Britiſh kings.

Among the proud defenders of our ancient liberty, ſcarcely any one ſeems entitled to ſuch ample notice as Caractacus, the victory over whom was acknowledged even by the conquerors of the world to have been one of the moſt important for the complete reduction of Britain that had ever been obtained.

What were the circumſtances of his early years, or whether his education at all differed from that which was uſually beſtowed upon his countrymen, we have no means to aſcertain. The earlieſt account we hear of him is in the reign of Claudius, when Aulus Plautius, the firſt Roman general who landed on the iſland after Julius Cæſar, commanded the expedition againſt Britain. The Roman commander, it appears, was unoppoſed at his landing, and having paſſed through the Britiſh ſtates upon the coaſt without reſiſtance, puſhed forward through the country in queſt of thoſe who were in arms. This was in the year 43, when, by the direction of his guide, he firſt overtook and defeated Caractacus.

The ſpirit of this illuſtrious chief, however, was not to be ſubdued at once: and though, in the progreſs of the Roman arms immediately ſubſequent to this tranſaction, we hear but little of Caractacus, we are not to ſuppoſe he was otherwiſe employed than in inſpiring his countrymen with the thoughts of vengeance.

Four years after Caractacus had loſt the greater part of his dominions Aulus Plautius was recalled. The affairs of the iſland were left in the hands of the legates or commanders of the legions; and in the interval which occurred till the appointment of Oſtorius Scapula as governor, A. D. 50, the Britons were enabled to gain ſome few advantages. Oſtorius having reſtored the tranquillity of the Roman province in the ſouth eaſt parts of Britain, marched againſt the Ceangi, who inhabited Cheſhire, and part of Lancaſhire, oppoſite to Ireland: but was ſoon recalled by the intelligence of an inſurrection among the Brigantes. It was not long, however, before he was called to encounter more determined enemies. Theſe were the Silures, (who occupied Herefordſhire, Radnor, Brecknock, Monmouth, Glamorgan, and, in general, *South Wales*), a people naturally brave and fond of liberty, but who, at that juncture, were rendered not only more confident and bold in themſelves, but more formidable to their enemies by the valour of their leader. Caractacus, who, as we have already mentioned, had loſt the greateſt part of his own dominions, willingly put himſelf at the head of this brave people, to make another effort for the deliverance of his country. He was ſkilled, we are told, in all the wiles and ſtratagems of ſavage warfare; and in point of local knowledge had greatly the advantage of the Roman general. And of this laſt, indeed, he availed himſelf by transferring the war into the country of the Ordovices, and by chuſing a place for the field of battle, which was every way favourable to his own army, and incommodious to his enemies. The ſpot he choſe, in Shropſhire, near the confluence of the Colun and Tame, is ſtill called *Caer Caradoc,* and will be deſcribed under the head of CASTLE. Its ramparts and entrenchments are yet viſible: and it exactly anſwers the deſcription given by Tacitus. It was ſituated on the ridge of a ſteep mountain. In ſome places where the ſides were acceſſible he fortified it with maſſy ſtones, heaped together in the form of a rampart. At the foot of the mountain flowed a river with fords and ſhallows of uncertain depth. And a hoſt of men guarded his entrenchments.

The Roman general, obſerving the deepneſs of the river, the ruggedneſs of the mountain, the ſtrength of the ramparts, and the loud alacrity of the enemy, was a little diſmayed at ſuch a ſucceſſion of dangers. As long, ſays Tacitus, as they fought with miſſive weapons, the Britons had the advantage. But when Oſtorius ordered his men to advance under a military ſhell, and level the pile of ſtones that ſerved as a defence to the enemy, a cloſe engagement followed. The Britons, unable to ſuſtain the ſhock, retired ſlowly towards the ridge of the mountain, and were eagerly followed by the Romans. In ſhort, the Britons, being without defenſive armour, the legions and auxiliaries made prodigious havoc; and the victory, at laſt, became deciſive. The wife and daughter of Caractacus were taken priſoners; his brother ſurrendered at diſcretion; and he himſelf fled for protection to Cartiſmandua, the queen of the Brigantes. But adverſity, ſays the Roman hiſtorian, has no friends. Cartiſmandua, who was his ſtep-mother, loaded him with irons, delivered him to the conqueror, and he, with his whole family, were carried priſoners to Rome. Even there the name of Caractacus was in high celebrity: and curioſity was eager to behold the hero who, for nine years, had made a ſtand againſt the Roman arms. The emperor too, proud of his priſoner, beſtowed the higheſt praiſe on the valour of the vanquiſhed king; he determined to render his entry into Rome as ſolemn and public as poſſible; and the people were ſummoned to behold the ſpectacle as worthy of admiration. The followers of the Britiſh chief, we are told, walked in proceſſion. The military accoutrements, the harneſs and rich collars, which he had gained in various battles, were diſplayed with pomp. The wife of Caractacus, his daughter, and his brother, followed next: he himſelf cloſed the melancholy train. The reſt of the priſoners, ſtruck with terror, deſcended to mean and abject ſupplications. Caractacus alone was ſuperior to miſfortune. With a countenance ſtill unaltered, not a ſymptom of fear appearing, no ſorrow, no condeſcenſion, he behaved with dignity even in ruin; and being placed before the tribunal delivered himſelf in the following manner:

"If, to the nobility of my birth, and the ſplendour of exalted ſtation, I had united the virtues of moderation, Rome had beheld me, not in captivity, but a royal viſitor and a friend. The alliance of a prince, deſcended from an illuſtrious line of anceſtors—a prince, whoſe ſway extended over many nations, would not have been unworthy of your choice. A reverſe of fortune is now the lot of Caractacus. The event to you is glorious, and to me humiliating. I had arms, and men, and horſes; I had wealth in abundance: can you wonder that I was unwilling to loſe them? The ambition of Rome aſpires to univerſal dominion: and muſt mankind, by conſequence, ſtretch their necks to the yoke? I ſtood at bay for years: had I acted otherwiſe, where, on your part, had been the glory of conqueſt, and where, on mine, the honour of a brave reſiſtance? I am now in your power: if you are bent on vengeance, execute your purpoſe; the bloody ſcene will ſoon be over, and the name of Caractacus will ſink into oblivion. Preſerve my life, and I ſhall be to late poſterity a monument of Roman clemency."

Claudius, it is enough to ſay, charmed with the boldneſs of his priſoner, pardoned both Caractacus and his family. The ſubſequent events of the Britiſh chieftain's life had no hiſtorian to pen them. And here we are obliged to cloſe his hiſtory.

The ſpeech of Caractacus, which is here tranſlated literally from Tacitus's Annals, was finely uſed by Mr. Maſon, in his celebrated dramatic poem. For the ſake of epiſodical incidents, however, he has departed from the ſtrict line of hiſtorical truth: and has transferred the honour of taking Caractacus priſoner, and ſending him to Rome, from Oſtorius to Aulus Didius. Tacit. Annal. l. xii. c. 35, et ſeq.

CARACTERE, *Fr.* as a dancer, *à demi-caractere,* in a ſtyle neither groteſque nor *terre à terre;* neither wholly comic nor ſerious.

CARADIVA, in *Geography,* an Aſiatic iſland, near that of Ceylon, at the weſtern point of the kingdom of Jaſnapatan: called by the Dutch *Amſterdam.*

CARAGA, in *Ancient Geography, Rugga,* a town of Africa, 2 leagues S.S.E. of Tiſdus, mentioned by Ptolemy.

CARAGACH, in *Commerce,* a cotton that comes from Smyrna, by the way of Marſeilles.

CARAGANA, in *Botany,* (from cara-caragan, the Tartar name). Lam. Encyc. Juſſ. 358. Vent. iii. p. 409. Claſs and Order, *diadelphia decandria.* Nat. ord. *Papilionaceæ,* Linn. *Leguminoſæ,* Juſſ.

Gen. Ch. *Cal.* one-leafed, bell-ſhaped-cylindrical, deeply divided on one ſide, with five ſhort teeth. *Cor.* papilionaceous; ſtandard egg-ſhaped, half erect; the ſides folded upwards; wings oblong; keel ſtraight, oblong, obtuſe. *Stam.* filaments ten, diadelphous. *Piſt.* germ ſuperior, oblong, ſmooth; ſtyle ſtraight; ſtigma ſmooth, truncate. *Peric.* legume oblong, inflated, ſmooth. *Seeds* four to ſix, egg-ſhaped, a little globular, not compreſſed.

Eſſ. Ch. *Calyx* five-toothed. *Stigma* ſmooth, truncate. *Legume* oblong, almoſt cylindrical. *Seeds* nearly ſpherical. La Marck has formed this genus for ſome plants which Linnæus referred to robinia, but which differ from its genuine ſpecies, both in the fructification and general habit. Their ſtigma is ſmooth, not downy; their legume nearly cylindrical, not compreſſed, and their ſeeds not flattened, as in robinia. Their leaves, moreover, are generally abruptly pinnated, and the petioles often elongated, terminating in a thorny point.

Sp. 1. C. *arboreſcens,* (robinia caragana, Linn. Sp. Pl. Gmel. Sib. iv. 17. n. 22. Aſpalathus arboreſcens, pinnis foliorum cretioribus, Amm. Ruth. p. 210. Duham. Arb. p. 188. n. 3.) "Leaves with about five pairs of leaflets, downy; ſtipules thorny; peduncles ſimple, faſciculated. *Stem* riſing to a tree, from ſix to ten feet high or more. *Branches* ſhort, ſtiff. *Leaves* faſciculated; leaflets elliptical, green above, veined, and paler green beneath; common petiole lengthened into a ſpinous point, ſometimes producing an odd leaf, but nevertheleſs evidently extended beyond it ; ſtipules in the ſecond year becoming a pair of ſhort, ſpreading ſpines. *Flowers* yellow, ſcentleſs. *Legumes* an inch and half long, ſmooth, rather cylindrical, pointed. A native of Siberia. It grows beſt in a light, ſandy ſoil, and is not injured by ſevere cold. Its leaves are good fodder for cattle, and are ſaid to produce a blue colouring matter. 2. C. *macrophylla*, Lam. "Leaflets in ſix pairs, roundiſh, mucronate, ſmoothiſh ; ſtipules ſpineſcent ; peduncles ſimple, ſolitary." A ſhrub, two or three feet high. *Leaves* alternate, abruptly winged. *Flowers* yellow, axillary, ſolitary ; peduncles rather long. A native of Siberia. 3. C. *ferox*, Lam. Illuſt. Pl. 607. *fig*. 1. (Robinia ferox, Pall. Roſſ. 70. tab. 44. Travels iii. app. 752. n. 125. tab. E *e*, *fig*. 2, 3. Germ. vol. iv. Pl. 25. p. 397, French Tranſlation. R. ſpinoſa, Linn. Sp. Pl. R. ſpinoſiſſima, Laxm. Nov. Com. Petrop. 15, 558. tab. 30. *fig*. 4.) "Leaflets oblong, narrow, mucronate ; ſtipules and petioles ſpineſcent." A ſhrub about five feet high. *Branches* ſlightly angular. *Leaves* alternate, abruptly winged : leaflets in four or five pairs, a little channelled, rather enlarged towards the ſummit, ending in a ſmall point ; common petiole ſharp-pointed, remaining after the fall of the leaflets, and becoming a permanent, woody, ſharp thorn about two inches long, and marked with the ſcars of the fallen leaflets ; ſtipules half-embracing the ſtem, membranous at their edges, ending in two ſharp ſpines. *Flowers* yellow, nearly ſeſſile, axillary, ſolitary, or in pairs ; calyx ſmooth, oblong, or cylindrical. *Legume* an inch long, ſtraight, ſmooth, acuminate. A native of Siberia and China. On account of its long, tough branches, and large ſtrong thorns, it is well adapted to make an impenetrable hedge ; and, as it is covered with flowers near the whole of the ſummer, is at the ſame time a very ornamental plant. It has the additional recommendation of being hardy, and able to bear the winters of our climate without injury. 4. C. *argentea*, Lam. Ill. Pl. 607. *fig*. 3. (Robinia halodendron, Pall. Travels, vol. ii. p. 471. t. w. German, vol. iii. pl. 6. p. 153, French Tranſlation, Linn. jun. Supp. 330.) "Leaflets in about two pairs, oblong, mucronate, waved, covered with a ſilvery down ; ſtipules and petioles ſpineſcent ; peduncles three-flowered." A ſhrub, four or five feet high, covered in all its parts with a whitiſh down, which gives it a ſilky appearance. *Branches* numerous, ſpreading, angular, in conſequence of three nerves proceeding from the baſe of each ſtipule. *Leaves* alternate ; leaflets enlarged towards their ſummit ; common petiole permanent, changing into a ſtraight, ſharp thorn, about an inch long ; ſtipules ſhort, recurved, ſpiny. *Flowers* reddiſh or purpliſh, ſweet-ſcented, axillary, often ſix-petalled, owing to the wings being doubled. *Legumes* ſhort, inflated, hard, remaining till the ſecond year. A native of Siberia, in dry, naked, ſalt ground, near the river Irtis. It flowers on its native ſoil in June, but has never produced flowers in our gardens, probably for want of the ſaline principle. Introduced by Dr. W. Pitcairn, in 1779. 5. C. *chamlagu*, (Robinia chamlagu, L'Herit. Stirp. Nov. 161. tab. 77. Aiton. Kew. iii. 54.) "Leaves in two pairs, petioled ; pairs diſtant ; ſtipules ſpineſcent ; peduncles one-flowered." A handſome ſhrub, much-branched, quite ſmooth, four or five feet high. *Branches* ſpreading, angular. *Leaves* alternate, or faſciculated, two or three together on the knots of the old branches ; common petiole ending in a ſhort, ſpiny point, deciduous, a little after the leaflets, not becoming a thorn. *Flowers* large, yellowiſh, axillary. A native of China, where it is called *chamlagu*. Introduced by Monſ. Richard, in 1773. 6. C. *digitata*, (Robinia fruteſcens, Linn. Sp. Pl. Aſpalathus fruteſcens major cortice aureo, Amm. Ruth. p. 206. n. 283.) "Leaves on ſhort petioles ; leaflets four, growing cloſe together in a digitate manner ; ſtipules ſomewhat ſpineſcent ; peduncles one-flowered." A ſhrub, about three feet high, branched from the bottom. *Branches* rod-like, pliant, of a ſhining yellowiſh colour, angular, loaded with leaves and flowers. *Leaves*, on the ſhoots of the year, alternate, with ſpineſcent ſtipules ; from the buds in bundles with unarmed ſtipules ; leaflets cluſtered, inverſely egg-ſhaped, attenuated at the baſe, ending in a ſmall, ſharp point ; petiole very ſhort, remaining after the leaflets, and hardening with the ſtipules into a triple ſpine. *Flowers* large, yellow, axillary ; peduncle jointed near the middle. There is a variety with longer, narrower leaves, which La Marck ſuppoſes is the *robinia pygmæa* of Linnæus and Pallas, but obſerves that the leaves in his plant are not ſo very obtuſe as Linnæus deſcribes them. Linnæus allows that his pygmæa reſembles the preceding, but ſays that it is of a dwarf ſtature, and more thorny. Both kinds were cultivated by Miller, who conſidered them as diſtinct. The Altaic plant, deſcribed by Pallas, is ſcarcely a ſpan high in its native ſoil, but grows larger when cultivated in gardens.

CARAGAS, in *Geography*, a province of Mindanao, in the Eaſt Indies, ſituate on the eaſtern coaſt, between Suliago and the Cape of St. Auguſtin, which lie north and ſouth. The ſeas on this coaſt are ſtormy. Caragas, as well as other parts of Mindanao, produces in great abundance that ſort of palm-trees, which are called ſagu, of the pith of which, reduced to meal, they make bread and biſcuit through the whole iſland, and more eſpecially on the coaſt of this province, near the river Butuan. The inhabitants of Caragas are a warlike people, and are accounted very brave, when employed either by ſea or land.

CARAGI, in *Commerce*, a name given to duties paid at the cuſtom-houſe in the territories of the grand ſignior, on the importation or exportation of goods. The term is alſo applied to the officers of the cuſtom-houſe, who collect theſe duties.

CARAGLIA, in *Geography*, a town of Piedmont, in the province of Coni ; 5½ miles N.W. of Coni.

CARAGNA, or KARAGNA, in *Pharmacy*. See CARANNA.

CARAGROUCH, a ſilver coin of the empire, weighing nine drams, which does not quite amount to a French crown, of three livres Tournois. At Conſtantinople it goes at 120 aſpers. There are four ſorts of them, equally current, and of the ſame value.

CARAGUATA, in *Botany*, Plum. gen. 10. See TILLANDSIA.

CARAHISSAR, in *Geography*. See APHIOM KARA-HISSAR.

CARAIBES. See CARIBBEES.

CARAIGOI, CARIGUEYA, or CARIGUEIA, in *Zoology*, according to Marcgrave, Piſa, and ſome other authors, the Braſilian name of the Virginian opoſſum. See DIDELPHIS *opoſſum*.

CARAIPA, in *Botany*, Lam. Enc. Juſſieu 434. Aubl. Guiana 561. a genus imperfectly known. Claſs and order, *polyandria monogynia*. *Cal.* Perianth deeply divided into five round ſegments. *Cor.* unknown. *Piſt.* Germ ſuperior. *Peric.* Capſule ſomewhat woody, rather three-ſided, acute, and recurved at its ſummit, three-celled, opening from the ſummit to the baſe with three permanent valves. *Seeds* one in each cell ; angular on the inner, convex on the outer ſide, attached to a large three-winged receptacle, which uniting with the valves, forms the partitions of the cells.

Sp. 1. C. *parvifolia*, Aub. tab. 223. fig. 1. "Leaves egg-ſhaped, acute, white with down underneath." A tree from fifteen to twenty feet high, much branched near the top.

*Branches* reddiſh. *Leaves* alternate, petioled, entire; ſtipules two, oppoſite, caducous. *Flowers* in terminal cluſters; capſules hairy. 2. C. *longifolia*, Aubl. tab. 223. fig. 2. “Leaves oblong egg-ſhaped, acute, grey underneath.” A larger and higher tree than the preceding. *Leaves* eight inches long, and three broad. 3. C. *latifolia*, Aub. tab. 224. fig. 3. “Leaves broad-egg-ſhaped, acuminate, aſh-coloured underneath.” 4. C. *anguſtifolia*, Aubl. tab. 224 fig. 4. “Leaves long, egg-ſhaped, acuminate, white underneath.” *Leaves* with more numerous lateral nerves, ten inches long, and two and a half broad. All the ſpecies are found in the foreſts of Guiana. The ſecond is called caripe by the natives.

CARAITES, or KARAITES, קראים, from קרא, *kera*, to read, a ſect among the ancient Jews: whereof there are ſtill ſome ſubſiſting in Poland, Ruſſia, Conſtantinople, Cairo, and other places of the Levant; though few or none are to be found in theſe weſtern countries. About the middle of the 16th century, a particular account was taken of their number; which in Poland was 2000; at Caſſa, in Crim Tartary, 12,000; at Cairo, 300; at Damaſcus, 200; at Jeruſalem, 30; in Babylon, 100; in Perſia, 600; amounting in the whole to 15,230, and being a ſmall number compared with the Rabbiniſts. It is their diſtinguiſhing tenet and practice to adhere cloſely to the words and letter of the Scripture, (as their name imports) excluſive of allegories, traditions, and the like.

Leo of Modena, a Rabbin of Venice, obſerves, that of all the hereſies among that people, before the deſtruction of the temple, there is none now left but that of the Caraim, a name derived from *micra*, which ſignifies the pure text of the Bible; becauſe of their keeping to the Pentateuch, obſerving it to the letter, and rejecting all interpretations, paraphraſes, and conſtitutions of the Rabbins. Aben Ezra, and ſome other Rabbins, treat the Caraites as Sadducees; but Leo de Juda calls them, more accurately, Sadducees reformed; becauſe they believe the immortality of the ſoul, paradiſe, hell, reſurrection, &c. which the ancient Sadducees denied. He adds, however, that they were doubtleſs originally real Sadducees, and ſprung from among them.

M. Simon, with more probability, ſuppoſes them to have riſen hence; that the more knowing among the Jews, oppoſing the dreams and reveries of the Rabbins, and uſing the pure texts of Scripture to refute their groundleſs traditions, had the name of Caraim given them; which ſignifies as much as the barbarous Latin, *Scripturarii*, i. e. people attached to the text of Scripture. The other Jews give them the odious name of Sadducees, from their agreement with thoſe ſectaries on the head of traditions. The real fact ſeems to have been, that the traditionary law was oppoſed, as a corruption of the true religion, by a numerous body, who ſtrenuouſly aſſerted the ſufficiency and perfection of the ancient written law, explained in its literal ſenſe. Among theſe were the Sadducees. But it is very probable, that the Sadducean tenets were highly offenſive to many pious men, who nevertheleſs were not diſpoſed to join thoſe who received the traditionary inſtitutions. Theſe, adhering ſimply to the letter of the Moſaic law, but at the ſame time refuſing to adopt the doctrine of the Sadducees, would of courſe become a ſeparate ſect, which would be diſtinguiſhed by ſome name expreſſive of their leading principle. It is not improbable that the oppoſite party gave them, in deriſion, the name of Scripturiſts, or Caraites. Hence we may conclude, that this ſect aroſe at the ſame time with thoſe of the Sadducees and Phariſees. From the Jewiſh records it may be inferred, that this ſect exiſted in the time of Hyrcanus. Accordingly it has been ſaid, that upon the diſſenſions between Hillel, the preſident of the Sanhedrim, and Shammai the vice-preſident, about 30 years before Chriſt, their reſpective ſcholars formed two parties, and took different names. Thoſe who adhered to Scripture only were called Caraim, or Scripturarii, and were followers of Shammai; and thoſe who were zealous for the traditions taught by the Scribes, or Rabbis, were called Rabbanim, Rabbiniſts, and were followers of Hillel. The Caraites juſtly boaſted the high antiquity of their principles, as being the followers of Moſes and the prophets, in oppoſition to human tradition; but when the doctrines of the Rabbis were generally adopted among the Jews, the Caraites were conſidered as ſchiſmatics. Scaliger, Voſſius, and Spanheim, erroneouſly, rank the Caraites among the Sabeans, Magi, Manichees, and Muſſulmen. Wolfang, Fabricius, &c. ſay, the Sadducees and Eſſeni were called Caraites, in oppoſition to the Phariſees: others take them for the doctors of the law ſo often mentioned in the goſpel: and in favour of this conjecture, has been alleged a tradition preſerved in the Jeruſalem Talmud, that there were in Jeruſalem 480 ſynagogues, each of which had a ſeparate apartment for the law, and another for the Talmud, or traditionary records: whence it has been inferred, that the Scripturiſts were a party diſtinct from the Traditionaries. The Scribes, whoſe office it was to expound the law, from the manner in which they are uſually mentioned in the New Teſtament, in conjunction with the Phariſees, may be concluded to have adopted, in their interpretations, the allegorical method of the Traditionaries and Cabbaliſts, and therefore to have commonly belonged to their party. Joſephus and Philo make no mention of them; whence it has been inferred, that they were more modern than either of thoſe authors. Perhaps, this ſect was not formed till after the collection of the ſecond part of the Talmud, or the Gemara; or not till after the compiling of the Miſchna.

The Caraites themſelves pretend to be the remains of the ten tribes led captive by Shalmaneſer. Wolfius, from the memoirs of Mardacheus, a Caraite, refers their origin to a maſſacre among the Jewiſh doctors, under Alexander Jannæus, their king, about one hundred years before Chriſt: becauſe Simeon, ſon of Schetach, and the queen's brother, making their eſcape into Egypt, there forged his pretended traditions; and, at his return to Jeruſalem, publiſhed his viſions, interpolating the law after his own fancy, and ſupporting his novelties on the notices which God, he ſaid, had communicated by the mouth of Moſes, whoſe depoſitary he was: he gained many followers; and was oppoſed by others, who maintained, that all which God had revealed to Moſes was written. Hence the Jews became divided into two ſects, the Caraites and Traditionaries: among the firſt, Juda, ſon of Tabbai, diſtinguiſhed himſelf; among the latter, Hillel. Wolfius reckons not only the Sadducees, but alſo the Scribes, in the number of Caraites. But the addreſs of the Phariſees prevailed againſt them all; and the number of Caraites decreaſed: and they long remained in obſcurity. At length, about the year of our Lord 750, Anan, a Babyloniſh Jew of the race of David, and Saul his ſon, both men of learning, publicly diſclaimed the authority of the traditionary doctrines of the Talmud, aſſerted the Scriptures to be the ſole rule of faith, and became heads of the Caraites, or Scripturarii, who again grew into repute, and increaſed in numbers. To this late period ſome have aſcribed the riſe of the Caraites. See Maſclef's Heb. Gram. vol. ii. p. 10. But from the hiſtory of the Rabbi Anan, who incurred great obloquy from the Phariſaical Rabbis for his hereſy, it clearly appears, that he was not the author, but the reſtorer of the Caraite ſect. Rabbi Schalomon, in the ninth century, maintained its credit; and among other perſons well ſkilled in the Jewiſh law, who adhered to it, we may mention Abu-Alphareus, who lived in Paleſtine, and wrote a commentary upon the Pentateuch, which added ſo much ſtrength to the intereſt of the Caraites, that the traditionary party thought it neceſſary to implore the aſſiſtance of the civil magiſtrate. Notwithſtanding this, however, they continued to hold their aſſemblies, and ſubſiſted, though in a declining ſtate.

The Caraites are but little known; their works coming only into very few hands, even among the greateſt Hebraiſts. Buxtorf never ſaw more than one; Selden two; but Mr. Trigland ſays, he has recovered enough to ſpeak of them with aſſurance. He aſſerts, that ſoon after the prophets had ceaſed, the Jews became divided on the ſubject of works, and ſupererogation: ſome maintaining their neceſſity from tradition; whilſt others, keeping cloſe to the written law, ſet them aſide; and it was from theſe laſt that Caraitiſm commenced. He adds, that after the return from the Babyloniſh captivity, the obſervation of the law being to be re-eſtabliſhed, there were ſeveral practices found proper for that end; and theſe, once introduced, were looked upon as eſſential, and appointed by Moſes; which was the origin of Phariſaiſm; as a contrary party, continuing to keep cloſe to the letter, founded Caraitiſm.

The modern Caraites, Leo of Modena obſerves, have their ſynagogues and ceremonies; they pretend to be the ſole proper Jews, or obſervers of the laws of Moſes: calling the reſt by the term *Rabbanin*, or *followers of the Rabbins:* theſe hate the Caraites mortally; refuſing to ally, or even to converſe with them, and treating them as *momzerim*, or baſtards; becauſe of their rejecting the conſtitutions of the Rabbins relating to marriages, repudiations, purifications of women, &c. This averſion is ſo great, that if a Caraite would become a Rabbiniſt, he would never be received by the other Jews.

The Caraites, however, do not abſolutely reject all kinds of traditions; but only ſuch as do not appear well grounded. Selden, who is very expreſs on this point, in his "Uxor Hebraica," obſerves, that beſides the mere text, they have certain interpretations, which they call *hereditary*, and which are proper traditions. Their theology only ſeems to differ from that of the other Jews, in that it is purer and clearer of ſuperſtition: they give no credit to the explications of the Cabbaliſts, chimerical allegories, nor to any conſtitutions of the Talmud, but what are conformable to the Scripture, and may be drawn from it by juſt and neceſſary conſequences.

Peringer obſerves of the Caraites in Lithuania, that they are very different, both in aſpect, language, and manners, from the Rabbiniſts, wherewith that country abounds. Their mother tongue is the Turkiſh; and this they uſe in their ſchools and ſynagogues. In viſage they reſemble the Mahometan Tartars. Their ſynagogues are placed north and ſouth; and the reaſon they give for it is, that Shalmaneſer brought them northward: ſo that in praying, to look to Jeruſalem, they muſt turn to the ſouth. He adds, that they admit all the books of the Old Teſtament; contrary to the opinion of many of the learned, who hold that they reject all but the Pentateuch.

Caleb, a Caraite, reduces the difference between them and the Rabbiniſts to three points: 1. In that they deny the oral law to come from Moſes, and reject the Cabbala. 2. In that they abhor the Talmud. 3. In that they obſerve the feaſts, as the ſabbaths, &c. much more rigorouſly than the rabbins do. To this may be added, that they extend the degrees of affinity, wherein marriage is prohibited, almoſt to infinity. Their diſtinguiſhing tenets may be ſummed up in the following particulars: that there is no other rule of faith and worſhip beſides the writings of Moſes and the prophets: that all oral traditions, and all allegorical and myſtical interpretations of the law are to be rejected: that all material beings were created by an uncreated Deity, of whom no reſemblance can be found in any thing which he has made: that he knows all things, and exerciſes a conſtant providence over all his works: that the human mind is ſubject to divine influence, but at the ſame time remains free in its volitions: that true penitence takes away guilt: that after death, the ſoul, if it be worthy, aſcends to the intellectual world, to live there for ever; but if it be guilty, it is conſigned to a ſtate of pain and ignominy: that God alone is to be worſhipped; and that faſts are to be ſtrictly obſerved. The preſent adherents of this ſect are ſaid to obſerve the moral precepts of their law more ſtrictly than their brethren, the Phariſaic Rabbinites, with whom, nevertheleſs, they are thought unworthy of eccleſiaſtical communion. Upon the whole, the Caraites are univerſally reckoned men of the firſt learning, of the greateſt piety, and of the pureſt morals of the whole nation.

See on this ſubject, Relandi Antiq. Hebræor. part ii. cap. 9. § 12. Trigland. de Secta Karæorum. Baſnage's Hiſt. of the Jews, book ii. chap. 8, 9. Brucker's Hiſt. Phil. by Enfield, vol. ii. p. 174, &c.

CARALIA, in *Ancient Geography*, a town of Aſia, in Pamphylia.

CARALIS, or Carales, now *Cagliari*, a town of the iſland of Sardinia, the capital, according to Florus, pillaged by Gracchus. It was of Phœnician foundation, according to Pauſanias, and had the right of Roman citizenſhip, according to Pliny. Ptolemy mentions a promontory and gulf of the name of "Carallis."

CARALLIA, or Carallis, an epiſcopal town of Aſia in Iſauria, according to Steph. Byz. or, according to the Notitia, in Pamphylia.

CARAMAN, in *Geography*, a town of France, in the department of the Upper Garonne, and chief place of a canton in the diſtrict of Ville-Franche; 5 leagues E.S.E. of Toulouſe. The place contains 2,292, and the canton 9,161 inhabitants; the territory includes 152½ kiliometres and 20 communes.

CARAMANGCE, in *Commerce*, a drug which comes from China. The Tonquineſe value it very much.

CARAMANIA, in *Geography*, one of the diviſions of Aſia Minor, now a province of Turkey in Aſia, ſituate on the ſouthernmoſt part, and extending from north to ſouth along the Mediterranean coaſt, which is its ſouthern boundary. It formerly comprehended the ancient countries of Lycia, Pamphilia, Piſidia, Lycaonia, Iſauria, Cilicia, part of Phrygia, Galatia, and Cappadocia. The Turks call the whole province Caraman-Ili. Its capital is Satalia. This province anciently belonged to the Caramanian princes, and was the laſt that ſubmitted to the arms of the Ottomans, about the year 1488. Caramania may be divided into Greater and Leſſer; the former comprehending all that part which lies to the north of mount Taurus, and the latter that part which lies ſouthward along the coaſt. The coaſt of Caramania is for the moſt part mountainous, and above theſe high mountains it is not uncommon to ſee, in clear weather, a very ſmall black cloud, no bigger than a bird. This globe of vapours is ſubject to great agitation; at firſt it is very ſmall, then ſuddenly ſpreads, contracts, appears and diſappears at intervals above the mountain, and changes its form every inſtant. How calm ſoever the atmoſphere may be, a ſudden and violent ſquall may be expected at the ſight of theſe inſulated clouds, which diſcharge the wind with ſo much rapidity and vehemence, that if a ſhip be not prepared to be overtaken by it, ſhe runs a great riſk of loſing part of her ſails, and even her maſts and yards. During the calm which precedes the ſtorm, a numerous ſhoal of fiſhes, cleaving the water level with its ſurface, and even darting above it, moves with great rapidity; and the agitation of theſe inhabitants of the depths of the ſea is always a certain preſage of an approaching and violent agitation in the atmoſphere and the waters.

CARAMANICO, a town of Naples, in the province of Abruzzo Citra.

CARAMANTA, a province of Terra Firma in South America, lying on the river Cauca, bounded N. by the diſtrict of Carthagena, E. by New Granada, and S. and W. by Popayan, in the audience of Sta. Fe. It is a valley ſurrounded by high mountains; and the natives extract from its waters very good ſalt. The capital, of the ſame name, lies in N. lat. 5° 18′. W. long. 72° 55′.

CARAMBIS, in *Ancient Geography*, a promontory of Aſia Minor, in the moſt northern part of Galatia, according to Ptolemy, and, according to Salluſt, between Heraclea and Paphlagonia; now "Capo Piſello."—Alſo, a town of Aſia in Paphlagonia.

CARAMBOLA, in *Botany*, Rheed. Mal. 3. 51. Burm. Zeyl. 148. Ind. 106. See AVERRHOA *Carambola*.

CARAMBU, Rheed. Mal. 2. 55. See JUSSIEUA *ſuffruticoſa*.

CARAMNASSA, in *Geography*, a river of Hindooſtan, which runs into the Ganges, near Buxar, in the country of Benares.

CARAMOUSSAL, in *Naval Architecture*, a Turkiſh veſſel, having a very high ſtern, and rigged nearly like a ketch; that is, it has main and mizen maſts and bowſprit, but neither foremaſt nor top-gallant maſts.

CARAMUEL DE LOBKOWITZ, JOHN, in *Biography*, was born at Madrid in 1606; and having entered into the Ciſtercian order, he poſſeſſed various church preferments in the Low Countries and in Germany, and at length became grand vicar of cardinal Harrach, archbiſhop of Prague. But ſuddenly abandoning the church, he aſſumed the military profeſſion, and in this capacity commanded a company againſt the Swedes, and acted as engineer and ſuperintendant of the fortifications in Bohemia. He then reſumed his former eccleſiaſtical character; and was ſucceſſively biſhop of Konigſgratz in Bohemia, of Campagna in Naples, and of Vigevano in the Milaneſe, at which latter place he died in 1682. His works are numerous, and indicate a ſingular genius; and it was ſaid of him, that he had invention in the eighth, or higheſt degree, eloquence in the fifth, and judgment in the ſecond. His "Eſſay on Cabaliſtic Grammar," was publiſhed at Bruſſels in 1642; and his "Daring or Audacious Grammar," at Frankfort in 1654. He wrote a large volume on the architecture of the temple of Solomon; and publiſhed at Vigevano a work, entitled "Λεπτοτατος, i. e. Subtiliſſimus, vel Nova Dialectico-Metaphyſica," diſtinguiſhed more by ſubtilty than by clearneſs and ſound ſenſe. He was a ſtrenuous defender of the doctrine of probability, and alſo of the infallibility of the pope. His theological writings that have been printed, amount to 7 vols. fol. Nouv. Dict. Hiſt.

CARAN, in *Geography*, a river of England, which runs into the Avon at Tewkeſbury in Glouceſterſhire.

CARANA, in *Ancient Geography*, a town of Aſia, in the Greater Armenia, which, according to Strabo, gave its name to the province "Caranitis." Steph. Byz. places Carana, which he ſays was built by the Romans, and alſo Caranitis, in Galatia.

CARANASI, in *Botany*, Rumph. Aub. 5. 49. See CAPPARIS *cruſtacea*.

CARANDA, a genus eſtabliſhed by Gærtner for a kind of palm, deſcribed by Rumphius, the fructification of which is imperfectly known. *Spadix* and *ſpatha* not known. *Cal.* coriaceous, three-leafed. *Cor.* none. *Peric.* none. *Seed* ſuperior, naked, pedicelled, affixed ſingly, or two or three together, to the baſe of the calyx. It is called, in the iſland of Ceylon, Ghalkarande, which means the ſtone kharande, to diſtinguiſh it from another kharande, or carandas, which Gærtner thinks is a ſpecies of Raudia; but, in his opinion, even a blind man may ſee that the ſeed deſcribed by him belongs to the family of palms. Linnæus refers a Carandas of Rumphius to his Cariſſa carandas.

CARANGAS, in *Geography*, a province and juriſdiction of South America, belonging to the archbiſhopric of Plata, which begins 70 leagues W. from the city of Plata, and extends above 50 leagues. The climate of this province is ſo cold that it is barren in corn and grain, &c. but it abounds in cattle. Here are a great number of ſilver mines conſtantly worked, among which that called Turco is very remarkable for a ſort of ore termed by miners Machacado; the fibres of the ſilver forming an admirable intertexture with the ſtone in which they are contained. Such mines are generally the richeſt. There are others found in the barren ſandy deſerts extending towards the weſt of the South Sea; in which are found, by digging in the ſands, detached lumps of ſilver, not mixed with any ore or ſtone, beſide that which adheres in ſome parts to the metal. The lumps are called "Papas," becauſe they are dug out of the ground like that root; and they have the appearance of melted ſilver; which proves that they are formed by fuſion. The ſize and figure of theſe lumps are very different, weighing from 2 to 60 and 150 marks; theſe laſt being a Paris foot in length. Juan and Ulloa's Voyage to S. America, by Adams, vol. ii. p. 153.

CARANJA, an iſland in the Indian ſea, near the Concan coaſt; 3 leagues S. of Bombay. N. lat. 18° 55′. E. long. 72° 44′.

CARANNA, in *Commerce*, a hard, brittle, reſinous gum, brought from ſome parts of the Weſt Indies, as Carthagena and New Spain; of an aromatic flavour; and ſometimes uſed in medicine as a cephalic.

The trees from which it runs, are like the palm-tree. When it is freſh, it is white; but as it grows ſtale, it becomes greyiſh inclining to green, in which condition it is ſent to Europe, where the white is ſeldom to be met with. It is brought in lumps wrapped up in leaves. To be of the beſt quality, it muſt be ſoft, of a pleaſant aromatic ſmell, and as white as ſnow. As this gum is very dear, it is ſeldom ſold unadulterated; and other ſorts are often ſubſtituted in its ſtead, which have not the ſame properties. When applied to the head, it has an extraordinary virtue to relieve it from pain; which renders it highly valuable. It produces the ſame effects in the joints; and is ſo much eſteemed in medicine, that it is become a proverb in pharmacy to ſay, Whatever the *tacamahaca* has not cured, the *caranna* will.

The Americans make a balm of it, which they pretend to be a ſovereign remedy for the cure of wounds, and the hæmorrhoids or piles.

CARANUS, in *Ancient Geography*, was, according to Strabo, the port of Aradus, ſituate in Syria, 7 leagues S.W. of Paltus.

CARANUSCA, a town of Belgic Gaul, occupying, as d'Anville thinks, the ſpot now called "Garſch," between Metz and Treves.

CARAPA, in *Botany*, Lam. Encyc. Aub. Guian. (Perſoonia, Willd.) Claſs and order, *octandria monogynia*.

Gen. Ch. *Cal.* perianth four-cleft. *Cor.* petals four; nectary cylindrical, eight-toothed, bearing the anthers. *Stam.* eight. *Piſt* germ ſuperior; ſtyle none; ſtigma large, ſalver-ſhaped. *Peric.* capſule one-celled, four-valved. *Seeds* numerous, angular, of various ſhapes, of a ſolid white ſubſtance, covered with a reddiſh, coriaceous ſkin, united together in an egg-ſhaped maſs, which entirely fills the capſule. La Marck. Willd. with the aſſiſtance of La Marck's figure.

Sp. 1. C. *guianenſis*, Aubl. Guian. Supp. p. 38. tab. 387. Lam. Ill. Pl. 301. (Perſoonia guareoides, Willd.) "Leaflets in numerous pairs, oblong, acuminate." A tree ſixty or eighty feet high, three or four feet in diameter. *Leaves* three feet long, alternate, abruptly winged; leaflets large, entire, ſmooth, ſometimes in not leſs than nineteen pairs. *Flowers* in compound racemes. A native of Guiana, where a thick bitter oil is expreſſed from the ſeeds, with which the inhabitants anoint themſelves as a ſecurity againſt the bite of inſects. Excellent maſts for ſhips are made of the trunk. 2. C. *moluccenſis*, Lam. Enc. (Granatum littoreum ſive martahal, Rumph. Amb. 3. p. 92. tab. 61.) "Leaflets in about three pairs, acutely egg-ſhaped." A tree ſmaller than the preceding, ſometimes producing two or three ſtems from the ſame root. *Leaves* four or five inches long; leaflets ſmooth. *Flowers*, according to Rumphius, dioicous, yellowiſh, ſmall, ſcentleſs, in compound, axillary racemes. *Fruit* large, containing from twelve to twenty ſeeds, ſimilar to thoſe of the preceding ſpecies.

As two other genera have been named in honour of Perſoon, one from New Holland, by Dr. Smith, and another from North America, by Michaux, we have retained the original name given by Aublet, though it muſt be acknowledged to be exceptionable, on account of its reſemblance to Caraipa, another of Aublet's genera.

CARAPACE, the thick, ſolid, firm ſhell, which covers the turtle or tortoiſe; and to which adhere thoſe fine tranſparent ſhells, which are known under the name of tortoiſe-ſhell, of which ſnuff-boxes and ſeveral ſorts of inlaid work are made.

CARAPALLA, in *Geography*, a river of Italy, in the kingdom of Naples, and province of Capitanata, which runs into the Adriatic; 9 miles S. of Manfredonia.

CARAPANATUBA, a river of Guiana, which empties itſelf into the Amazon, at about one third of a degree of the equator above fort Macapa. By the treaty between France and Portugal, 29th September 1801, it was concluded that the boundaries of French and Portugueſe Guiana ſhall be determined in future by that river. Theſe limits ſhall follow the courſe of the river to its ſource, whence they ſhall take a direction to the grand chain of mountains which divides the two rivers, and follow the windings of that chain to the point neareſt to Rio Branco, between the ſecond and third degree N. of the equator.

CARAPE, in *Ancient Geography*, a town of Aſia, in the interior part of the Leſſer Armenia, towards the mountains. Ptolemy.

CARAPICHEA, in *Botany*, Aubl. Guian. See CALLICOCCA *carapichea*.

CARAPITO, in *Geography*, a town of Portugal, in the province of Beira; 4 leagues N. of Pinhel.

CARAPO, in *Ichthyology*, a fiſh deſcribed by Marcgrave, of which he ſays there are two kinds, the firſt having a long and thin body, like a knife-blade, with the back thick, the belly very thin and narrow, and the tail pointed; the ſecond narrower in proportion to its length, and without ſpots. The head of both is flat and pointed, and the lower jaw runs out a little farther than the upper. The latter character ſeems to prove that theſe fiſhes are varieties of *Gymnotus faſciatus*, rather than of *Gymnotus carapo*, as ſome writers imagine. Gmelin conſiders the *Carapo* of Marcgrave as his *Gymnotus carapo*, which cannot be the fact if we may depend on Marcgrave, the Gmelinian fiſh of that name having the upper jaw longeſt inſtead of the lower one. See GYMNOTUS *carapo*, and *faſciatus*.

CARARA, in *Botany*. Piſ. Braſ. tab. 241. See AMARANTHUS *viridis*.

CARARA, in *Commerce*, a weight at Leghorn, and in other parts of Italy, uſed in the ſale of wool and cod-fiſh, equivalent to ſixty pounds of that country.

CARARA, anciently *Luna*, in *Geography*, a ſmall town of Tuſcany, celebrated for the white marble which was dug in its quarries, and which was not inferior to the marble of Paros either with reſpect to the fineneſs of its grain, or the beauty of its whiteneſs. The fineſt ſpecies of this marble is almoſt as hard as porphyry.

CARAROS, or CARARUS, in *Ancient Geography*, a town of Africa Propria, in the vicinity of Targarum.

CARASCHULLI, in *Botany*. Rheed. Mal 2. tab. 47. See BURLERIA *buxifolia*.

CARASCOF, in *Geography*, a town of Poland, in the palatinate of Kiov, 34 miles W. of Bialacerkiew.

CARASOU, a town of Leſſer Tartary in the Crimea, once very populous, but burnt by the Ruſſians in 1737.—Alſo, the name of two rivers in Turkey, one of Natolia, in Caramania, the other in Romania.—Alſo, the name of a lake, being part of the canal which forms the moſt ſoutherly mouth of the Danube, called by the Turks "Carakirmen."

CARASSIUS, in *Ichthyology*, a ſpecies of CYPRINUS, which inhabits the freſh waters of Europe; *Caraſſius* of Marſ. Danub. ſuppoſed by ſome to be the ſame with the Rud of Engliſh writers. See CYPRINUS *caraſſius*. Obſ. Among the old writers caraſſius was conſidered as a kind of generic name for the carp, bream, &c.

CARASYRA, in *Ancient Geography*, one of the forts of Thrace, erected by the emperor Juſtinian in the province of Rhodope.

CARAT. See CARACT.

CARATÆ, in *Ancient Geography*, the name of a people who formed part of the ancient Jacæ, and who inhabited the coaſt of the Caſpian Sea, on the banks of the Jaxartes.

CARA-TARTARS, in *Geography*, or *black Tartars*, a people of Aſia; formed by a body of Turks, incorporated by Kuli-khan the grandſon of Gengiſ-khan in his army, when he was ſent to Iran by Mangou-chan, his brother, emperor of the Moguls. They now occupy the countries of Geta and Touran in Aſia.

CARATCHOLIS, a people of Aſia in Georgia, N. of mount Caucaſus. They are alſo called "Karakinks" and black Circaſſians.

CARATING, in *Chemiſtry*, a term uſed to denote the mixture or combination of gold with other metals. Thus, "red carating" expreſſes the mixture of gold with copper, to diſtinguiſh it from the leſs uſual one, made with ſilver, and denominated "white carating," and alſo in contradiſtinction to the "mixed carating" or combination of gold, ſilver, and copper. The degree of this combination or alloy is expreſſed by carats and grains. See CARACT.

CARATTERE, *Ital.* character. A muſical term, in ſpeaking of a ſong of two ſtrains; *aria di due caratteri*; of which the firſt is generally *cantabile*, and the ſecond *bravura*. See CANTABILE and BRAVURA.

CARAVACA, or *St. Cruz de Caravaca*, in *Geography*, a town a town of Spain, in the province of Murcia; 40 miles W S.W. of Murcia.

CARAVAGA, a river of Peru in South America, famous for its golden ſands.

CARAVAGGIO, in *Biography*. See ANGELO AMERIGI.

CARAVAN, or CARAVANNE, in the eaſt, a troop or company of travellers, merchants, and pilgrims, who for their greater ſecurity march in a body through the deſerts, and other dangerous places, infeſted with Arabs and robbers.

The word comes from the Arabic *cairawan*, or *cairoan*; and that from the Perſian *kèrvan*, or *cârvân*, *negociator*, *a trader*, or *dealer*. Vid. Peritiſ. Itin. Mund. ed. Hyde. p. 61.

There is a chief, or aga, called "caravan-bachi," who commands each caravan, and has under him a number of janizaries, or other forces, ſufficient for their defence. The caravans encamp every night near wells, or rivulets known to the guides; and obſerve a diſcipline as regular as in war. They chiefly uſe camels for their vehicles, becauſe of their enduring much fatigue, eating little, and paſſing three or four days without drinking.

In this manner trade was carried on, particularly by the nations near the Arabian gulf, from the earlieſt period to which hiſtorical information reaches. See CAMEL.

The grand ſignior gives one fourth part of the revenue to Egypt, to defray the expence of the caravan that goes yearly from Cairo to Mecca, to viſit Mahomet's tomb: the devotees, in this caravan, are from 40,000 to 70,000; accompanied with ſoldiers to protect them from the pillage of the Arabs, and followed with 8 or 9,000 camels, laden with all neceſſary proviſions for ſo long a paſſage acroſs deſerts.

There are two regular caravans which go yearly to Mecca; the firſt from Damaſcus, compoſed of the pilgrims from Europe and Aſia; the ſecond from Cairo, for the Mahometans of Barbary.

Damaſcus is the grand rendezvous for all the pilgrims from the north of Aſia, as Cairo is for thoſe from Africa. Beſides the natives of Aleppo who go to Mecca, numbers from Perſia and the northern provinces aſſemble in that city in their way to Damaſcus, for which place the caravan ſets out immediately after the leſſer Bairam. When the caravan ſets out from Aleppo, it is conveyed for a few miles by the governor and grandees in proceſſion, and many of the pilgrims being accompanied ſtill farther in their way by their women and kinſmen, all is in commotion on the road to Damaſcus for ſeveral days after the Bairam. However, the number of pilgrims who go from Aleppo to Mecca is ſaid to be much leſs conſiderable now than formerly. This probably is owing in part to the decaying ſpirit of Mohammediſm, but more to the decline of the trade with Mecca; for it was uſual with the merchants, formerly, to make the journey ſeveral times in their life, and the caravans were accuſtomed to return, laden with Indian and Arabian merchandize. After the junction of the caravans from other towns at Aleppo, it proceeds to Damaſcus; and the number of pilgrims every year is ſaid to amount to from 30 to 50,000; many of them repair hither four months before the time, but the greateſt number only at the end of the Ramadan. Damaſcus then reſembles an immenſe fair; nothing is to be ſeen but ſtrangers from all parts of Turkey, and even Perſia; and every place is full of camels, horſes, mules, and merchandize. At length, after a preparation of ſome days, this vaſt multitude ſet out confuſedly on their march, under the conduct of the baſhaw or pacha of Damaſcus, and, travelling by the confines of the deſert, arrive in 40 days for the feſtival of Bairam at Mecca; the diſtance between the two cities being, according to the moſt moderate eſtimate, above a thouſand miles. As this caravan traverſes the country of ſeveral independent Arabs, it is neceſſary to make treaties with the Bedouins, to allow them certain ſums of money, for a free paſſage, and to take them for guides. On this ſubject frequent diſputes occur between the Scheiks, of which the pacha avails himſelf to make a better bargain; but in general the preference is given to the tribe of Sardia, which encamps to the ſouth of Damaſcus, along the Hauran: the pacha ſends to the Scheik a mace, a tent, and a peliſſe, to ſignify that he takes him as his chief conductor. From this moment it is the Scheik's buſineſs to furniſh camels at a ſtated price; theſe he hires likewiſe from his tribe and his allies: the pacha is reſponſible for no damages, and all loſſes are on his own account. On an average, 10,000 camels periſh yearly; which form a very advantageous article of commerce for the Arabs. It muſt not be imagined that the ſole motive of all the expences, riſks, and fatigues, incurred by the pilgrims, is devotion. Pecuniary intereſt has a conſiderable ſhare in theſe expeditions, and, indeed, permiſſion to trade, during the pilgrimage, is granted by the Koran, chap. ii. p. 23. The caravan affords the means of engroſſing every lucrative branch of commerce; and almoſt all the pilgrims convert it into a matter of ſpeculation. On leaving their own country, they load themſelves with merchandize, which they ſell on the road; the ſpecie ariſing from this, added to what they have brought with them, is conveyed to Mecca, where they exchange it for muſlins and Indian goods from Malabar and Bengal, the ſhawls of Caſhmire, the aloes of Tonquin, the diamonds of Golconda, the pearls of Bahrein, pepper, and a great quantity of coffee from Yemen. Sometimes the Arabs of the deſerts deceive the expectation of the merchant, by pillaging the ſtragglers, and carrying off detached parties of the caravan. Of the predatory ſpirit of the Arabs it is a ſingular proof, that although all their independent tribes are zealous Mahometans, yet they make no ſcruple of plundering the caravans of pilgrims, while engaged in performing one of the moſt indiſpenſable duties of their religion. A remarkable inſtance of this occurred in the year 1757; when 60,000 pilgrims were plundered and diſperſed over the deſert, a great number deſtroyed by ſword or famine, women reduced to ſlavery, immenſe riches loſt, and above all, a ſolemn act of religion ſacrilegiouſly violated. This produced a commotion in the empire, which was not ſoon forgotten. The plundering Arabs were the allies of Daher, who received them at Acre, and there permitted them to ſell their booty. The Porte, indeed, loaded him with the bittereſt reproaches, but he endeavoured to exculpate himſelf, and to appeaſe the Divan, by ſending the white banner of the prophet to Conſtantinople. In general, however, the pilgrims arrive ſafe; and in this caſe their profits are very conſiderable. At all events they are recompenſed in the veneration attached to the title of "Hadji," or "Hadgy," (pilgrim); and by the pleaſure of boaſting to their countrymen of the wonders of the Caaba (See CAABA) and mount Arafat; of magnifying the prodigious crouds of pilgrims, and the number of victims, on the day of the Bairam; and by recounting the dangers and fatigues they have undergone, the extraordinary figure of the Bedouins, the deſert without water, and the tomb of the prophet at Medina.

By means of this caravan, Damaſcus is become the centre of a very extenſive commerce. By Aleppo the merchants of this city correſpond with Armenia, Anatolia, the Diarbekir, and even with Perſia. They ſend caravans to Cairo, which, following a route, frequented in the time of the patriarchs, take their courſe by Djeſr-Yakoub, Tabaria, Nablous, and Gaza. In return they receive the merchandize of Conſtantinople and Europe, by way of Saide and Bairout. The home conſumption is balanced by ſilk and cotton ſtuffs, which are manufactured here in great quantities, and are very well made; by the dried fruits of their own growth, and ſweetmeat cakes of roſes, apricots and peaches, of which Turkey conſumes to the amount of about 40,000l. The remainder, paid for by the courſe of exchange, occaſions a conſiderable circulation of money in cuſtom-houſe duties, and the commiſſion of the merchants. This kind of commerce has exiſted in theſe countries from the earlieſt antiquity. It has flowed through different channels, according to the changes of the government, and other circumſtances; but it has every where left very apparent traces of the opulence produced by it. See Volney's Travels in Egypt and Syria, vol. ii. Ruſſell's Aleppo, vol. ii.

The caravan from Cairo in Egypt is compoſed, not only of pilgrims from every part of Egypt, but of thoſe that arrive from all the ſmall Mahometan ſtates on the African coaſt of the Mediterranean, from the empire of Morocco, and even from the negro kingdoms on the Atlantic. During the months of April, May, and June, in every year, theſe rich caravans from the interior of Africa arrive at Cairo; carrying thither a conſiderable quantity of three ſpecies of gums, elephants' teeth, tamarinds, parrots, oſtrich feathers, gold duſt, and black ſlaves; and in return they convey into their own country falſe pearls, coral, amber, glaſs-ware, broad ſwords, cloths, and all kinds of clothing, which are purpoſely made by the manufacturers of Cairo to ſuit the African taſte. When aſſembled, the caravan conſiſts at leaſt of 50,000 perſons, and the number of camels employed in carrying water, proviſions, and merchandize is ſtill greater. In the month of Ramadan, viz. one month previous to the departure of this caravan from Cairo, begins the fair, vulgarly called "Maûlâd (or, the birth of the prophet). Strangers of every nation and religion repair hither to diſpoſe of their merchandize. At this fair European merchandize is the moſt required; and of coin the ſequin of Venice is preferred. The pilgrims purchaſe them at the higheſt price, as it is the coin from which they derive the greateſt profit. The women are not leſs anxious to obtain them than the men, for the purpoſe of ornamenting the head and boſom. The journey, which, in going from Cairo, and returning hither, is not completed in leſs than 100 days, is performed wholly by land; and as the route lies moſtly through ſandy deſerts, and barren uninhabited wilds, which ſeldom afford any ſubſiſtence, and where often no ſources of water can be found, the pilgrims always undergo much fatigue, and ſometimes muſt endure incredible hardſhips. Of this caravan an early and good deſcription is publiſhed by Hakluyt, vol. ii. p. 202, &c. Maillet (Deſcript. de l'Egypt, part ii. p. 212, &c.) has entered into a curious and minute detail with regard to it: and Pocock (vol. i. pp. 188, 261, &c.) has given a route, together with the length of each day's march, which he received from a perſon who had been 14 times at Mecca. Upon the return of the caravan to Cairo, another fair begins, more ſumptuous and rich than that already mentioned; where ſtrangers barter for new commodities, and part with thoſe which they had not been able to ſell at the departure of the caravan. Thus the commerce of Cairo extends by land as far as Mecca in conſequence of this yearly pilgrimage, and alſo into the interior of Africa by the caravans of pilgrims.

Great as theſe caravans are, we muſt not ſuppoſe that all the pilgrims who viſit Mecca belong to them. Such conſiderable additions are received from the extenſive dominions of Perſia, from every province of Hindooſtan, and the countries to the eaſt of it, from Abyſſinia, from various ſtates on the ſouthern coaſt of Africa, and from all parts of Arabia, that when all are aſſembled, they have been computed to amount to two hundred thouſand. In ſome years the number is further increaſed by ſmall bands of pilgrims from ſeveral interior provinces of Africa, the names and ſituation of which are juſt beginning to be known in Europe. For this laſt fact we are indebted to the Aſſociation for promoting the diſcovery of the interior parts of Africa. In the report of the committee of the privy council on the ſlave trade, and alſo in Brown's Travels in Africa, (chap. 18.) other particulars are contained: and it appears that the commerce carried on by caravans in the interior parts of Africa, is not only widely extended, but of conſiderable value. Beſides the great caravan which proceeds to Cairo, and is joined by Mahomedan pilgrims from every part of Africa, there are caravans which have no object but commerce; which ſet out from Fez, Algiers, Tunis, Tripoli, and other ſtates on the ſea-coaſt, and penetrate far into the interior country. Some of them take no leſs than 50 days to reach their place of deſtination; and as the medium of their rate of travelling may be eſtimated at about 18 miles a day, the extent of their journey may be eaſily computed. As both the time of their outſet, and their route are known, they are met by the people of all the countries through which they travel, who trade with them. Indian goods of every kind form a conſiderable article in their traffic, in exchange for which the chief commodity they can give is ſlaves. Three diſtinct caravans are employed in bringing ſlaves, and other commodities, from the interior of Africa to Cairo. One of them comes ſtraight from Mourzouk, the capital of Fezzan; another from Sennaar, and the third from Fûr. They do not arrive at fixed periods, but after a greater or leſs interval, according to the ſucceſs they may have had in procuring ſlaves, and ſuch other articles as are ſuited to the market, the orders of their reſpective rulers, and various other accidental circumſtances. The Fezzan caravan is under the beſt regulations. The merchants from that country employ about 50 days in their paſſage from Mourzouk to Cairo; which city they as often as poſſible contrive to reach a little before the commencement of Ramadan, that ſuch as find themſelves inclined to perform the pilgrimage may be prepared to accompany the emir of Miſr. The ſale of their goods ſeldom employs them in the city much more than two months; after the expiration of which, thoſe who have no deſign of viſiting Mecca, return to their native country. The arrival of this caravan is generally annual. Thoſe who compoſe this caravan from Mourzouk to Cairo are collected from the empires of Bornou and Caſhna, from the extenſive kingdom of Caſſaba, and from ſeveral of the Negro ſtates. It ſeldom conſiſts of leſs than 100, or of more than 300 travellers; and begins its journey on the laſt week of October, or in the firſt of the ſucceeding month. At the cloſe of the ſeventh day it arrives at Temiſſa, and in two days more, at a lofty, rocky, uninhabited, and barren mountain, called Xanibba. Here they recruit their goatſkin bags with water from the only well which theſe heights afford, and then deſcend to a vaſt and dreary deſert, whoſe hilly ſurface, for four ſucceſſive days, preſents nothing to the eye but one continued extent of black and naked rock, to which, for three days more, the equally barren view of a ſoft and ſandy ſtone ſucceeds. On the eighth day they reach the vaſt mountain of Ziltan, the paſſage of which occupies four days of labour; and in the four ſucceeding days they croſs the ſultry plain that extends with its barren ſands from the foot of the mountain to the verdant heights of Sibbeel, and at the cloſe of the following day they arrive at the town of Augéla. From Augéla, which is ſubject to Tripoli, and famous for the abundance and excellent flavour of its dates, they proceed in one day to the village of Gui Xarrah, and another brings them to the long aſcent of the mountain of Gerdóbah. Deſcending from this height, where they procure, during five days of their paſſage over it, but a ſcanty ſupply of unpalatable water, they enter the narrow plain of Gegabib, which is ſandy and uninhabited, but fertile in dates, annually gathered by the people of Duna, a town dependent on Tripoli, and ſituate on the coaſt at the diſtance of eight days' journey from Gegabib. After a march of three days they are conducted to a deſolate mountain called Buſelema, that furniſhes only water; and in three days more they enter the dominions of the independent republic of See-wah. From See-wah, the capital, the caravan proceeds in a ſingle day to the miſerable village of Umſeguér, ſituate at the foot of the mountainous deſert of le Mágra, whence, after ſeven days, it arrives at the hill of Huaddy l'Ottrón, diſtinguiſhed by a ſmall convent of three Chriſtian monks, under the protection of Cairo. By theſe monks the travellers are hoſpitably entertained; and thence they continue their courſe, and on the fifth day reach the city of Cairo, from whence, at the proper ſeaſon, they purſue their route to Mecca.

The other two caravans from Sennaar and Fûr, are extremely various in their motions; ſometimes not appearing in Egypt for the ſpace of two or even three years, and ſometimes two or more diſtinct caravans arriving in the ſame year. The perpetual changes in their ſeveral governments, and the caprices of their deſpots, are in a great degree the occaſion of this irregularity. The road alſo between theſe two places and Cairo is often infeſted by bodies of independent Arabs, as that of Sennaar by the Ababdé and Shaikié, and that of Fûr by the Cubba-Beeſh and Bedaiât. The departure of a caravan from Dar-Fûr forms an important event: it engages the attention of the whole country for a time, and even ſerves as a kind of chronological epocha. The period of their arrival at Cairo is as uncertain as that of their departure; for they travel indifferently either in winter or ſummer. The journey from Aſſûan to Sennaar requires much leſs time than that from Aſſiût to Dar-Fûr. The roads of the deſert are not diſtinguiſhable by any permanent marks; and as they are perfectly ignorant of the compaſs, and ſo imperfectly acquainted with the fixed ſtars, they are often at a loſs for the road, and ſometimes deviate into dangerous paths. In paſſing from Dar-Fûr to Egypt, they conſider 2000 camels and 1000 ſlaves a large caravan. Camels are indiſpenſable for theſe long and fatiguing journeys, and therefore they are reared by the Arabs and Jelabs with great care: nevertheleſs, the merchant pays nearly as much for the camels to carry his merchandize as he did for the commodities themſelves. Horſes are little uſed by the Jelabs: they generally furniſh themſelves with Egyptian aſſes, which are afterwards ſold at Soûdan at an advanced price. The cuſtomary food of the drivers and ſervants of the caravan conſiſts of the milk of the camel, with a few dates, together with the meal of barley, or of Indian corn, which is ſometimes ſeaſoned with oil, to which the merchant ſuperadds, for his own uſe, the dried fleſh of the camel, or of ſheep, and concludes his repaſt with coffee. Water is drawn from the wells, when they occur, in leather buckets, that form a part of the travelling equipage of the caravan, and is carried in the ſkins of goats, through which, however, though tarred both within and without, it is often exhaled by the heat of the noon-day ſun. A very eaſy mode of conveyance is provided for the women and children, and for perſons either ill or infirm. Six or eight camels are yoked together in a row, and ſeveral tent poles are placed in parallel lines upon their backs: theſe are covered with carpets, and bags of corn are ſuperadded to bring the floor to a level, as well as to ſoften the harſhneſs of the camel's movement: other carpets are then ſpread, and the traveller ſits or lies down with as much convenience as if he reſted on a couch. The proviſions of the Dar-Fûr caravan are ſcanty and indifferent, nor are any of them furniſhed with dried meat as is common with the Fezzaners. Few uſe coffee and tobacco, and the reſt content themſelves with a leathern bag of flour, another of bread baked hard, a leathern veſſel of honey or treacle, and another of butter. In travelling from Dar-Fûr to Egypt, another article is much uſed, eſpecially for the ſlaves, which is the grain called millet. Of this they take a quantity after it has been coarſely ground, and cauſing it to undergo a ſlight fermentation, they make of it a paſte. When they uſe it they add water, and it becomes a tolerably palatable food, allaying thirſt whilſt it aſſuages hunger. Experienced travellers, among every ten camels laden with merchandize, charge one with beans, and ſtraw chopped ſmall, which, ſparingly given, ſerve them during the greater part of the journey. Water, inſtead of being conveyed in goat ſkins, the evaporation of which no ſkill can entirely prevent, is carried in ox hides, which the Jelabs, on their march from Soûdan to Egypt, form into capacious ſacks, and properly ſeaſon with tar or oil. A pair of theſe is a camel's load. The "Cabba-Beeſh" and the "Bedaiât," when they make any attempt on the caravans, commonly ſhew themſelves between Leghea and Bir-el-Malka. But this road is ſo ill provided with any kind of accommodation for man or beaſt, that neither the wandering tribes, nor the ferocious animals which infeſt other parts of the continent, are commonly found there. The Egyptians and other whites, therefore, though they commonly carry fire-arms with them from the North, generally take advantage of the market of Fûr, and return without any. The natives of Soûdan are furniſhed with a light ſpear, the head of which is made of unhardened iron of their country. They have alſo a ſhield about three feet long, and 1½, or ¾ foot broad, compoſed of the hide of the elephant, or hippopotamus, very ſimple in its conſtruction. No regular caravan of Hadgis leaves Dar-Fûr, but a number of the natives make their way to Mecca, either with the caravan of merchants trading to Egypt, or by way of Suakem or Jidda.

Upon the whole we may obſerve, that independently of thoſe caravans that are formed from religious motives, moſt of the inland commerce of the Eaſt has been for many ages carried on by means of caravans. In former times, caravans traverſed the whole latitude of Aſia in 243 days, from the Chineſe Ocean to the ſea-coaſt of Syria. Silk was immediately delivered to the Romans by the Perſian merchants, who frequented the fairs of Armenia and Niſibis; but this trade, which, in the intervals of truce, was oppreſſed by avarice and jealouſy, was totally interrupted by the long wars of the rival monarchies. However, the cities of Samarcand and Bokhara were advantageouſly ſituated for the exchange of the various productions of Aſia; and their merchants purchaſed from the Chineſe the raw or manufactured ſilk, which they tranſported into Perſia for the uſe of the Roman empire. In the vain capital of China, the Sogdian caravans were entertained as the ſuppliant embaſſies of tributary kingdoms; and if they returned in ſafety, the bold adventurer was rewarded with exorbitant gain. But the difficult and perilous march from Samarcand to the firſt town of Shenſi, could not be performed in leſs than 60, 80, or 100 days. As ſoon as they had paſſed the Jaxartes they entered the deſert; and the wandering hordes, unleſs they are reſtrained by armies and garriſons, have always conſidered the citizen and the traveller as the objects of lawful rapine. In order to eſcape the Tartar robbers, and the tyrants of Perſia, the ſilk caravans explored a more ſouthern road; they traverſed the mountains of Thibet, deſcended the ſtreams of the Ganges or the Indus, or expected with patience, in the ports of Guzerat and Malabar, the annual fleets of the Weſt. But the dangers of the deſert were found leſs intolerable than toil, hunger, and the loſs of time; and therefore the attempt was ſeldom renewed; and the only European who has paſſed that unfrequented way, applauds his own diligence, that in nine months after his departure from Pekin, he reached the mouth of the Indus.

The ſame intercourſe which was anciently kept up by the provinces in the north-eaſt of Aſia with Hindooſtan and China, ſtill ſubſiſts. Among all the numerous tribes of Tartars, the demand for the productions of theſe two countries is very conſiderable. In order to ſupply them, caravans ſet out annually from Bokhara, Samarcand, Thibet, and ſeveral other places, and return with large cargoes of Indian and Chineſe goods. But the trade carried on between Ruſſia and China, in this part of Aſia, is by far the moſt extenſive and beſt known. Some connexion of this kind has probably been kept up between them from the earlieſt period; but it greatly increaſed after the interior parts of Ruſſia were rendered more acceſſible by the conqueſts of Zenghis Khan, and Tamerlane. The commercial nations of Europe were ſo well acquainted with the mode of carrying on this trade, that ſoon after the Portugueſe had opened the communication with the Eaſt, by the Cape of Good Hope, an attempt was made, in order to diminiſh the advantages which they derived from this diſcovery, to prevail on the Ruſſians to convey Indian and Chineſe commodities through the whole extent of their empire, partly by land carriage and partly by means of navigable rivers, to ſome port on the Baltic, from which they might be diſtributed through every part of Europe. This ſcheme was rendered practicable by the conqueſts of Ivan Baſilowitz, and the genius of Peter the Great. Though the capitals of the two empires were ſituated at the immenſe diſtance of 6378 miles from each other, and the route lay for above 400 miles through an uninhabited deſert, caravans travelled from the one to the other. But though it had been ſtipulated, when this intercourſe was eſtabliſhed, that the number of perſons in each caravan ſhould not exceed 200, and though they were ſhut up within the walls of a caravanſera during the ſhort time they were ſuffered to remain in Pekin, and were allowed to deal only with a few merchants, to whom a monopoly of the trade with them had been granted; yet, notwithſtanding all theſe reſtraints and precautions, the jealous vigilance with which the Chineſe government excludes foreigners from a free intercourſe with its ſubjects was alarmed, and the admiſſion of the Ruſſian caravans into the empire was ſoon prohibited. After various negotiations, it was agreed, that two towns ſhould be built almoſt contiguous, on the boundaries of the two empires, Kiachta inhabited by Ruſſians, and Maimatſchin by the Chineſe. To theſe all the marketable productions of their reſpective countries are brought by the ſubjects of each empire; and the furs, the linen and woollen cloth, the leather, glaſs, &c. of Ruſſia, are exchanged for the ſilk, the cotton, the tea, the rice, the toys, &c. of China. See RUSSIA and CHINA.

M. Bougnon, geographer of the duke of Lorraine, has given a treatiſe of the caravans of merchants in Aſia, wherein he ſhews of what they are compoſed; how many ſorts there are; the ſeveral uſes of the different ſorts of animals in them; the price given for them; the officers and men appointed to conduct them, and the pay of each; with their manner of marching, halting, fighting, treating, &c.

In the heavy caravans, to five hundred elephants there are a thouſand dromedaries, and at leaſt two thouſand horſes, eſcorted by four thouſand cavaliers. Two men are required to lead each elephant; five to three dromedaries; and ſeven to twelve camels. Such a number of ſervants joined with the officers and paſſengers, the number whereof is not limited, renders the body very formidable; the paſſengers, indeed, are not obliged to fight, but in caſe they refuſe, proviſion will ſcarcely be allowed them afterwards, even for their money.

As few of the Arab princes have any other ſubſtance than what they can get by pillage, they keep continually ſpies on foot to give them intelligence of the departure and motions of caravans, which they frequently attack with ſuperior forces: in caſe of repulſe, they come to an accommodation; but if the caravan be beaten, it is abſolutely plundered, and the whole guard made ſlaves; though more indulgence is ſhewn to ſtrangers. The taking of a ſingle caravan ſometimes enriches a prince for ever.

The profits to be made in a caravan, during its march, are often incredible; Mr. Bougnon gives inſtances where, by repeated bargains and exchanges, a perſon has made twenty thouſand crowns out of a ſingle gold watch, and thirty louis d'ors.

Any dealer is at liberty to form a company, in order to make a caravan. He in whoſe name it is raiſed, is conſidered as the caravan-bachi, or chief of the caravan, unleſs he appoint ſome other in his place. If there be ſeveral merchants equally concerned, they elect a caravan-bachi; after which they appoint officers to conduct the caravan, and decide all controverſies which may ariſe during the journey.

In the Eaſt, days' journies are diſtinguiſhed into journies of horſe-caravans, and caravans of camels: thoſe of horſes are equal to two of camels. Mr. Rennell, in an ingenious diſſertation on the rate of travelling, as performed by camels, (Phil. Tranſ. vol. lxxxi. p. 129—145) of which ſome account has been given under the article CAMEL, has ſhewn how to apply the hourly rate of the camel's travelling in caravans as an uſeful ſcale to the geography of Africa; and it will alſo ſerve for the eſtimate of diſtances and of time, in other countries, where camels and caravans are in uſe. He diſtinguiſhes caravans into *heavy* and *light*. Camels loaded with from 500 to 600 pounds, which are a camel's load, form what is called the *heavy* caravan; and *light* caravans, on the contrary, are applied to camels under a moderate load, or perhaps little more than half-loaded. Having ſettled the mean daily rate of the heavy caravan at 18.64 Britiſh miles, reckoning $2\frac{1}{2}$ miles for each hour, and 19.06, if taken at 2.56, and the mean rate of the light caravan, 22.17 miles, at $2\frac{1}{2}$, and 22.7 at 2.56; he obſerves, that, in order to apply the ſcale with effect to the African geography, it is neceſſary to ſtate the number of days that the caravans uſually halt on the road. From various inquiries he concludes that, at an average, one halt muſt be allowed to $12\frac{1}{2}$ travelling days; and this, of courſe, muſt be deducted from the aggregate of the diſtance: or ſhould it be averaged on each day, the heavy caravan day muſt be reckoned at 17.14 miles inſtead of 18.64; and that of the light caravan 20.4, inſtead of 22.17, when the hourly rate is taken at $2\frac{1}{2}$ miles. It further remains to be ſtated from the proportion that the road diſtance bore to the direct diſtance, what length in direct diſtance, and in geographical miles, may be allowed for each day, for the heavy caravan, on lengths of journey, and over tracts of country ſimilar to the route of Mr. Carmichael from which the eſtimate is made. It appears that on the 28 days between Aleppo and Rackama (oppoſite Meſjid Ali) the mean length of the day's journey in direct diſtance is about 15¼ geographical miles; and on the whole 45 days between Aleppo and Buſſorah, 13.8 ſuch miles. If allowance be made for halts, theſe will require a deduction of 8 parts in 100 to be made from the groſs amount of the whole journey, when applied to the purpoſes of geography. Mr. Carmichael counted the camel's ſteps in order to aſcertain a ſcale of diſtance. Mr. Holford alſo did the ſame, and meaſured the length of them on the ground. The former gentleman counted the double ſteps, or rather the return of the ſame foot of a camel on which he rode, for an hour together on 20 different days, at ſuch times as admitted of the greateſt variation in the rate of motion. He found the greateſt number of ſteps to be 2420, the leaſt 2086; and the mean of the whole 20 hours was 2200. The latter gentleman reckoned the greateſt 2240, leaſt 2060; mean 2150. They both report the double ſtep to be 5½ feet. The reſult of the former account is 2.29 Britiſh miles per hour; of the latter 2.24: each allowed his diſtance accordingly in his journal. But Mr. Rennell obſerves, that their computed diſtances fall very ſhort of the truth. The error probably originated from their meaſuring too ſmall a number of ſteps on the ground as the foundation of their calculation. The reaſon of the great variation in the number of paces, in a given time, is the plenty or ſcarcity of the deſert ſhrubs, on which the camels feed as they go on; and then ſuch experiments become uſeleſs unleſs the quality of the deſert were deſcribed in every part of it.

Some have reckoned five ſorts of caravans, viz.

Caravan, *heavy*, compoſed of elephants, dromedaries, camels, and horſes.

Caravan, *light*, in which there are but few elephants.

Caravan, *ordinary*, that in which there are no elephants.

Caravan *of horſes*, that in which there are neither camels nor dromedaries, but only horſes.

Caravans, *ſea*, companies of merchant veſſels, loaden with goods, and convoyed by ſhips of war. Such are thoſe which paſs from Conſtantinople to Alexandria.

Caravan is alſo an appellation given to the voyages, or campaigns, which the knights of Malta are obliged to make at ſea againſt the Turks and corſairs, in order to arrive at the commanderies and dignities of the order. They are thus called, becauſe the knights have frequently ſeized the caravan going from Alexandria to Conſtantinople.

CARAVANIER, a perſon who leads the camels and other beaſts of burden uſed in the caravans of the Eaſt.

CARAVANSERA, a large public building, or inn, deſtined to receive and lodge the caravans.

The word comes from the Arabic *cairawan*, or Perſian *karwan* or *cârvân, a caravan*, and *ſerai, a large houſe*.

Of theſe caravanſeras, or as Chardin calls them, *caravanſerai*, there are a great number throughout the eaſt; erected out of the charity and magnificence of the princes, &c. of the ſeveral countries, for the accommodation of travellers. They are called by the Turks "Kanes;" and are ſituate ſometimes in the towns and villages; ſometimes at convenient diſtances upon the road.

Thoſe of Schiras and Caſbin in Perſia, are ſaid to have coſt ſixty thouſand crowns each. They are open to people of all religions and countries, without any queſtions aſked or any money required.

The caravanſerai are uſually huge ſquare buildings, with a ſpacious court in the middle of them. They are encompaſſed with galleries and arches, under which runs a kind of banquette, or elevation, ſome feet high, where travellers reſt themſelves, and make their lodgings as well as they can; their baggage and the beaſts that carry them being faſtened to the foot of the banquette. Over the gate, there is frequently a ſort of little chambers, which the caravanſeraſkier lets out at a very dear rate to ſuch as wiſh to be retired.

Though the caravanſeras ſerve in lieu of inns, yet there is this eſſential difference between them and our inns, that the traveller finds nothing at all in the caravanſera either for himſelf, or his cattle; but muſt carry all his proviſions and neceſſaries with him. They are chiefly built in dry barren deſert places; and are generally furniſhed with water from a great diſtance, and at a vaſt expence; there being no caravanſera without its well of water. There are ſeveral of them in cities; where they ſerve not only as inns, but as ſhops, warehouſes, and even exchanges.

There are ſome carayanſeras where moſt things may be had for money; and as the profits of theſe are conſiderable, the magiſtrates of the cities to whoſe juriſdiction they belong, take care to ſtore them well; they have an inſpector who fixes the price of lodging, without appeal. Such well-furniſhed reſting places appear to have been known in Judæa in the time of our Lord; ſince he ſuppoſes the good Samaritan committed the poor wounded man to the care of the hoſt, or keeper of the caravanſera, and promiſed at his return to pay him for whatever things the diſtreſſed traveller required, and which the keeper furniſhed him with. Luke x. 34, 35.

There are few cities in the eaſt without their caravanſerai; eſpecially within the dominions of the great Mogul. Thoſe of Conſtantinople, Iſpahan, and Agra, the capitals of theſe three empires, are diſtinguiſhed for their magnificence and commodiouſneſs. The caravanſeras of Schiras and Caſbin, conſiderable cities of Perſia, are alſo in high reputation, and little inferior to thoſe of the capital.

In Turkey, none but the grand ſignior's mother and ſiſter, with the viſiers and baſhaws who have been in three battles againſt Chriſtians, are allowed to build a caravanſera.

CARAVANSERASKIER, the director, ſteward, or intendant of a caravanſera.

At Iſpahan there are caravanſeras in manner of halls or exchanges, where goods are laid up, and expoſed to view; for which the caravanſeraſkier is accountable, in conſideration of a certain fee.

CARAVEL, the name of a veſſel formerly uſed by the Spaniards and Portugueſe; the maſts were inclined, in place of being upright as uſual, with triangular ſails. Veſſels of this deſcription ſailed faſt, and would lie near the wind.

Caravel is alſo the name of a ſmall veſſel employed on the coaſt of France in the herring fiſhery; and theſe are commonly from twenty-five to thirty tons burthen. French veſſels in the ſame employment in the Britiſh channel are called Trinquarts; theſe are in general from twelve to fifteen tons burden.

CARAVELLA, in *Zoology*, a ſpecies of Meduſa deſcribed in Sloane's Hiſtory of Jamaica. See Medusa *Caravella.*

CARAVI, in *Geography*, a ſmall iſland in the Grecian Archipelago. N. lat. 36° 55′. E. long. 23° 36′.

CARAVILLA, a town of Naples, in the country of Moliſe; 12 miles N.W. of Moliſe.

CARAUNA, in *Ichthyology*, the name of a ſmall Braſilian fiſh deſcribed by old writers as being of a fine bright red colour, with innumerable black ſpots all over it. The exact ſpecies is uncertain, but it appears to be a fiſh of the Labrus genus.

CARAUSIUS, in *Biography*, a native of Menapia or Maritime Flanders, who uſurped the empire in Britain in the third century. According to Dr. Stukely (Hiſt. of Carauſius) he was a native of St. David's, and a prince of the blood royal of Britain. Although ſprung from the meaneſt origin "viliſſimè natus," according to the expreſſion of Eutropius, he advanced himſelf by his naval ſkill, as a pilot, and by his experience and valour in maritime expeditions, to ſtations of truſt and ſervice, under Probus and his ſucceſſors. Having by the diſplay of his talents ingratiated himſelf with Maximian, this emperor employed him in conducting an enterpriſe againſt the Franks and Saxons, who by their piracies had rendered the navigation of the ſeas impracticable. With this view he was appointed to the command of a ſquadron, aſſembled at Geſſoriacum or Boulogne. Carauſius availed himſelf of the opportunity which this office of truſt afforded him for acquiring, by various captures of veſſels richly laden with ſpoil, ample treaſures; which he appropriated to his own uſe. Maximian, enraged by his treacherous and fraudulent conduct, determined to put him to death without trial. The crafty Carauſius foreſaw and prevented the ſeverity of the emperor. By his liberality he had attached to his intereſt the fleet which he commanded; and from the port of Boulogne he ſailed over to Britain; where, perſuading the legion, and the auxiliaries that guarded the iſland, to join his party, he boldly aſſumed the imperial purple, and the title of Auguſtus, and ſet at defiance the juſtice and the arms of his injured ſovereign. This event happened, during the joint empire of Diocleſian and Maximian, A. D. 286. In order to ſecure his uſurpation he augmented his fleet, attached to his cauſe by a variety of artful methods the Franks and Saxons, and whilſt he defended the frontiers of his dominions againſt the Caledonians of the North, invited from the continent a great number of ſkilful artiſts, and diſplayed, in various coins which are ſtill extant, his taſte and opulence. He ſtill preſerved the poſſeſſion of Boulogne and the adjacent country. His fleets rode triumphant in the channel, commanded the mouths of the Seine and of the Rhine, ravaged the coaſts of the ocean, and diffuſed beyond the columns of Hercules the terror of his name. Under his command, Britain deſtined in a future age to obtain the empire of the ſea, already aſſumed its natural and reſpectable ſtation of a maritime power. As he had ſeized the fleet of Boulogne, he had deprived his maſter of the means of purſuit and revenge. After a diſappointed effort by a new armament, conſiſting of imperial troops unaccuſtomed to the ſea, Diocleſian and his colleague reſigned to Carauſius the ſovereignty of Britain, and reluctantly admitted their perfidious ſervant to a participation of the imperial honours. His civil government, whilſt it laſted, was oppreſſive and tyrannical. He held the people in a ſtate of perfect ſubjugation, and at the ſame time indulged his own paſſions and thoſe of his mercenaries, upon whom he depended for ſupport, without reſtraint and limitation. At length, however, the aſſociation of the two Cæſars reſtored new vigour to the Roman arms; and the conduct of the Britiſh war was committed to the brave Conſtantius. His firſt enterpriſe was directed againſt Boulogne, which after an obſtinate defence ſurrendered, A. D. 292; and thus a conſiderable part of the naval ſtrength of Carauſius fell into the hands of the beſiegers. During the three years which Conſtantius employed in preparing a fleet adequate to the conqueſt of Britain, he ſcoured the coaſt of Gaul, invaded the country of the Franks, and deprived the uſurper of the aſſiſtance of theſe powerful allies. Before theſe preparations were finiſhed, Conſtantius received information of the death of the tyrant, who was murdered, A. D. 294 (ſays Gibbon) or A D. 293 (Blair's Tables) by his firſt miniſter Allectus. See Allectus. Crevier's Rom, Emp. vol. ix. Gibbon's Hiſt. vol. ii.

CARAWAWANG *Point*, in *Geography*, the eaſt point of the bay of Batavia in the iſland of Java.

CARAWAY, in *Botany*. See Carus *carui*.

Caraway, in *Agriculture*, a plant ſometimes cultivated for the ſeed. It is a ſort of crop much cultivated in Eſſex on rich old leys of a ſtrong clayey or loamy nature, in low ſituations. It is ſometimes ſowed with coriander and teaſel, and harveſted the ſecond year at the expence of four ſhillings an acre. It is commonly threſhed upon a cloth in the field, being very apt to fall in gathering, which is done the beginning of July. It commonly requires two good hoeings; one in April, the other in the beginning of June. The produce of this crop has often been very great, even as much as twenty hundred weight per acre, which has always a market in London; but ſometimes as low as 12s. and frequently as high as 50s. on an average, 24s. or 26s. per hundred weight. It does not perfect its ſeed till the ſecond or third year, when the land is fit to be ploughed up for wheat. For this crop the land ſhould be prepared by two or more ploughings, and have a portion of manure applied where poor. See Carus.

CARAXERON, in *Botany*. Vaill. act. 1722. p. 264. See Illecebrum *vermiculatum*.

CARAZOWINY, in *Geography*, a river on the eaſt coaſt of South America, between the river Cauroya to the E.S.E. and Uracho to the W.N.W. It large and navigable; but viſited chiefly by a few Dutch ſhips, who come hither to load a kind of dyers' wood.

CARBACA, or Garbaca, in *Ancient Geography*, a town of Aſia, in Paropamiſus. Ptolemy.

CARBANA, a town of Aſia Minor, in Lycia. Steph. Byz.

CARBANIA, a ſmall iſland of the Mediterranean, between Sardinia and the continent of Italy. Pomp. Mela. Some have thought that it is the *Barpana* of Pliny, and the modern *Carboli*.

CARBANTORIGUM, a town in the northern part of Britain, which, according to Ptolemy, belonged to the Selgovæ. Horſley places it at Bardanna on the river Nith, above Dumfries, and Camden at Carlaverock, below it; and it was therefore probably ſituated where Dumfries now ſtands, or a little below it. The name ſeems to be derived from "Caer vant o rig," a town near the mouth of a river. Baxter places it at Melroſs.

CARBASA *Caryſtia*, a term uſed by many of the ancient writers to expreſs pieces of cloth made of the *linum incombuſtibile*, or aſbeſtos ſtone, which being found plentifully about Caryſtium, was thence called by the name of the place. Pauſanias calls it *linum Carpaſum*, for the ſame ſort of reaſon; Carpaſus, a town in the iſland of Cyprus, being a place famous for affording large quantities of the ſtone in its neighbourhood.

CARBATIA, in *Ancient Geography*, a place of Italy in Liguria, at a ſmall diſtance ſouth of the Padus, or Po.

CARBENSIS *aqua*, in the *Materia Medica*, the name of a mineral water of Germany, of which Hoffman from Petzelerus has given the following account. All about the place of its origin, and along the canals through which it paſſes, it depoſits an earthy and ferruginous matter, which concretes into a ſtony hardneſs. When any alkaline liquor, whether fixed or volatile, is added to theſe waters, they become turbid, and precipitate a whitiſh earthy matter to the bottom of the veſſel; after the evaporation of the water they leave a *ſal enixum*, and an alkaline earth; two quarts of them yield two ſcruples and ten grains of the earth, and twelve grains of the ſalt. If it be kept for any time in a glaſs, or earthen veſſel, it depoſits a ſediment of a yellow ochreous earthy matter, and when immediately taken from the ſpring, it changes to a bluiſh brown colour, on being mixed with galls. It contains a very large portion of a ſubtile mineral ſpirit; for if a long-necked veſſel be filled half full with it, and the orifice ſtopped with the thumb, the whole, on a little ſhaking, ſends up a froth to the top; and when the thumb is taken off, the water ſquirts out to ſeveral feet diſtance. It makes an effervesſcence on mixing oil of vitriol with it; but this laſts but a very little time. From the whole, it ſeems to contain a large quantity of calcareous earth, and ſome ſmall portion of ferruginous matter; whence it purges both by ſtool and urine, though moſtly the latter way: the former operation, which is pretty conſtant, is owing to this alkaline earth meeting with an acid in the *primæ viæ*, and being by it changed into a bitter purging ſalt, of the nature of Glauber's.

CARBEQUI, or *Aſper of copper*, a coin which is current in the province of Georgia in Aſia; particularly at Tefflis, the capital. Forty carbequis are equal to the "abagi," and ten carbequis to the "chaouri."

CARBERRY, in *Agriculture*, a name applied, in ſome places, to the gooſeberry.

CARBERY, in *Geography*, the name of a large barony in the S.W. of the county of Cork, province of Munſter, Ireland. The diſtrict of this name formerly included ſome of the adjoining baronies, and is ſuppoſed to have been ſo called from an Iriſh prince who governed it. It is ſtill the largeſt barony in Ireland, containing 39 pariſhes, and 196,321 Iriſh plantation acres, which is more than many counties. It has, therefore, been found convenient, in managing county buſineſs, to divide it into Eaſt and Weſt Carbery. It is a very wild, mountainous, unimproved country, with a bold rocky coaſt, and many harbours.

A Latin poem of dean Swift's, called "Carberiæ rupes," was written in 1723, whilſt on a viſit to a clergyman in this barony. Dr. Smith, who made more than once the ſame little voyage along the coaſt which the dean had done, obſerves that the dean's deſcriptions were as juſt as his numbers were beautiful. The poem, and a tranſlation of it by Dr. Dunkin, may both be ſeen in Smith's Hiſtory of Cork, from which this article is principally taken. In ſome parts of Carbery the linen manufacture is ſucceſsfully carried on, eſpecially about Dunmanway and Cloghnakilty. Carbery, or Carbury, is alſo the name of two other baronies, one in the county of Sligo, and the other in the county of Kildare.

Carbery, a ſmall iſland in Dunmanus bay, county of Cork, Ireland, which ſhelters veſſels from weſterly winds, but has ſhoals in its neighbourhood, which require attention to guard againſt. It is ſometimes called *Innis Carbery*. N. lat. 51° 31′. W. long. 9° 34′. M'Kenzie, Beaufort.

CARBET St. Jaques, a town of Martinico, in the Weſt Indies. N. lat. 14° 39′. W. long. 61° 10′.

CARBI, in *Ancient Geography*, a people of Arabia Felix, according to Diodorus Siculus.

CARBIA, a place in the iſland of Sardinia, on the route from Tibulæ to Sulci. Anton. Itin.

CARBINA, a place of Italy in Japygia, mentioned by Athenæus, who ſays that it was taken by the Tarentins.

CARBINI, in *Geography*, a town of the department of Liamone, (iſland of Corſica), and chief place of a canton in the diſtrict of Sartene; 5 miles E. of Tallano. The canton contains 2806 inhabitants.

CARBO *aquaticus*, in *Ornithology*. See Pelecanus *Carbo*, the Corvorant.

CARBON, in *Chemiſtry*.

### § 1. *Of Carbon.*

This ſubſtance abounds largely in all vegetable and animal bodies, as well as in the mineral kingdom, yet it is of very rare occurrence in a ſtate of abſolute purity. When uncombined with any foreign matter, it is tranſparent, colourleſs, intenſely hard, and cryſtallized; and, both on account of its beauty and value, is placed at the head of the gems under its commercial and mineralogical name Diamond.

Diamond was formerly ſuppoſed to be incombuſtible, and the firſt hint at its real nature was given by Newton. This philoſopher having obſerved that inflammable bodies poſſeſs, in proportion to their denſity, a greater power of refracting the rays of light than any other ſubſtances, was induced to rank the diamond among them, on account of the eminent degree in which it poſſeſſed this property. This conjecture was verified, in 1691, by the members of the Academy del Cimento at Florence, who conſumed ſeveral diamonds by placing them in the focus of a lens. Francis I. emperor of Germany, afterwards witneſſed the deſtruction of ſeveral more by the heat of a furnace. Theſe experiments were repeated by Macquer, Rouelle, Darcet, and Cadet, who aſcertained, that by the concurring action of air and heat, diamond was not only evaporated, but actually burnt with flame; they alſo proved that when the air was excluded the higheſt heat of a furnace produced little or no effect on this ſubſtance.

In 1772, an experiment was made by Lavoiſier, which may be conſidered as the firſt attempt to effect a chemical analyſis of diamond. He burnt a few grains of this ſubſtance in a jar of common air, confined over mercury, by means of a very powerful lens, and found that the pure part of the air had diſappeared, as well as a conſiderable proportion of the diamond, and that the reſidual air abounded with carbonic acid: repeating the ſame proceſs only with the ſubſtitution of an equal weight of highly burnt charcoal, he found preciſely analogous effects to take place, and therefore concluded that diamond and charcoal in their chemical eſſence were very ſimilar to each other. In 1785, M. Morveau diſcovered that diamond, when dropped into melted nitre, burns like charcoal, and without leaving any reſiduum. This fact ſuggeſted to Mr. Tennant a method of analyſing diamond, which was effected with complete ſucceſs. Into a gold tube, cloſed at one end, and terminating at the other in a curved glaſs tube, were put a quarter of an ounce of nitre and 2½ grains of diamonds; the tube was then kept at a full red heat for an hour and a half, and when its contents were afterwards examined, the diamonds were found to have entirely diſappeared, and the nitre was changed into ſub-carbonat of potaſh; to a ſolution of this ſalt muriat of lime was added, and thus the carbonic acid was transferred to the lime: from this carbonat of lime the carbonic acid was expelled by means of the muriatic acid, and was found to amount to 9.03 grains. Hence 27.6 parts of diamond and 72.4 of oxygen conſtitute 100 of carbonic acid. But, according to Lavoiſier, 28 parts of charcoal, and 72 of oxygen conſtitute 100 of carbonic acid; therefore diamond and pure charcoal may be conſidered as chemically the ſame.

Morveau has ſince endeavoured to invalidate the experiment of Mr. Tennant, and to ſhew that diamond is pure carbon and that charcoal is an oxyd of carbon, but his experiment is ſo manifeſtly incorrect as to merit no ſort of confidence.

A further proof of the analogy between charcoal and diamond is furniſhed by an ingenious experiment of Clouet's, in which ſome pure bar-iron being expoſed to a high heat, in contact with diamond, this latter ſubſtance was found to have diſappeared, and the iron to be converted into ſteel.

But though diamond is the pureſt form of carbon, yet its high value, its hardneſs, and denſity, forbid it to be uſed in ordinary chemical experiments; all the ſucceeding facts, therefore, relate to that leſs pure kind of carbon which is obtained by expoſing common CHARCOAL, or, ſtill better, lamp-black, to a high heat in cloſe veſſels.

Carbon, or prepared charcoal, is an excellent conductor of galvaniſm and electricity, but tranſmits caloric with very great difficulty; a ſhort piece may be held by one end while it is heated red at the other, without conveying any notable warmth to the hand.

It is inſoluble in water, and even the combined action of air and water produces hardly any perceptible effect upon it; hence it is that ſtakes of wood that are charred on the outſide will laſt much longer without rotting than the ſoundeſt timber that has not undergone this preparation.

Charcoal is not fuſible by the greateſt heat that can be applied: if expoſed to a very high temperature in cloſe veſſels it loſes little or nothing of its weight, but ſhrinks in ſize, and becomes proportionably more compact, denſe, and ſonorous, and acquires a deep velvet black colour. But though charcoal is unalterable by mere heat, yet when heated red in the open air, it ſpeedily undergoes combuſtion, and is converted into CARBONIC ACID; pure oxygen gas produces, as might be expected, a much more powerful effect on this ſubſtance than atmoſpheric air does; a piece of charcoal barely heated at one end to redneſs and plunged into this gas, immediately burns with an intenſely white glow, and is rapidly changed into carbonic acid.

Water, although it is, as we have already mentioned, incapable of diſſolving carbon, is yet very obſtinately retained by it, partly on account of its porous texture, and in part probably on account of a ſtrong mutual affinity ſubſiſting between them. When, however, charcoal is red hot, or nearly ſo, it decompoſes any water with which it may happen to be in contact, and unites with both the elements of this ſubſtance; producing with the oxygenous baſe, according as this is added to ſaturation or not, carbonic acid and carbonous oxyd; and with the hydrogenous baſe forming a heavy inflammable air, called carburetted hydrogen or hydrocarbonat.

Newly prepared charcoal is capable of abſorbing various gaſſes, with remarkable facility, and in conſiderable proportions. This fact had been obſerved by Fontana, Lametherie, Prieſtley, Scheele, and Morveau, but the firſt important ſeries of experiments on this ſubject was publiſhed by Morozzo, ſince which time Meſſrs. Rouppe and Van Noorden of Rotterdam have made a conſiderable and very valuable addition of facts on this curious ſubject. The charcoal for the experiment being highly ignited in an open fire, to expel all the moiſture and gaſeous ſubſtances which it may contain, is quickly removed, and extinguiſhed by being plunged under mercury, or incloſed in an air-tight metallic box; when quite cool it produces the following effect on the various gaſſes.

One part of charcoal is capable of abſorbing three times its bulk of atmoſpheric air in four or five hours; of oxygen gas there is abſorbed, at firſt rapidly, and afterwards more ſlowly, 2.8 times the bulk of the charcoal. Azot and hydrogen are taken up inſtantaneouſly, but only in the proportion of 1.6 of the former, and 1.8 of the latter. Of nitrous gas 8.5 parts are very ſlowly, and of carbonic acid 14.3 parts are very rapidly abſorbed. The gaſſes thus taken up undergo no change except of form, nor are the reſidues at all altered, and they may be all again ſeparated from the charcoal by diſtillation, at the temperature of boiling water. If charcoal ſaturated with hydrogen in the way deſcribed is introduced into oxygen gas, or even into atmoſpheric air, a conſiderable abſorption of the oxygen takes place, and combines with the hydrogen, forming water, and at the ſame time the temperature riſes to about 103° Fahr. The reſult is the ſame if the experiment is inverted, that is, if charcoal charged with oxygen is introduced into hydrogen gas. Charcoal ſaturated with hydrogen is even capable of decompoſing nitrous gas, the oxygen being abſorbed and the azot alone remaining in the elaſtic ſtate. Charcoal ſaturated with azot is alſo capable of decompoſing atmoſpherical air, by abſtracting the oxygenous part, which is a remarkable proof how adverſe the gaſeous ſtate is to chemical combination.

Carbon is capable of combining with ſulphur; the ſubſtance hence reſulting is called carburetted ſulphur, and almoſt all that is known as yet concerning it is due to the united inveſtigations of Clement and Deſormes, two French chemiſts. It is thus prepared. Fill an earthenware tube with ſmall pieces and powder of newly burnt charcoal, fix it in a ſlanting direction in a furnace, and lute to the lower end a glaſs tube, dipping it into ſome water contained in a receiver. Faſten a glaſs tube alſo to the upper extremity of the earthen pipe, and fill it with ſhort cylindrical pieces of ſulphur, and fit a cork to the open end of the glaſs tube with a moveable wire paſſing through its centre, by which the pieces of ſulphur may be puſhed at pleaſure towards the earthen pipe. The apparatus being completed, heat the pipe very gradually, and as ſoon as the gas caſually contained in the charcoal is driven out, cauſe the ſulphur, by means of the wire, to approach the heated part of the apparatus. Allow it to remain at ſuch a diſtance that it may melt as ſlowly as poſſible, and run down among the charcoal; and if theſe precautions are duly obſerved, a yellowiſh oily liquor will ſoon be perceived in the terminating glaſs tube, which will drop into the water of the receiver, and collect at the bottom of the veſſel, without at all uniting with the ſupernatant fluid. The carburet of ſulphur thus obtained is a tranſparent liquid, colourleſs when pure, but generally of a yellowiſh-green tinge, and of a diſagreeable ſlightly pungent odour, differing, entirely, however, from that of ſulphuretted hydrogen. The ſpecific gravity of carburetted ſulphur is about 1.3. It evaporates in the air with nearly the ſame rapidity as ether, and, like this fluid, ſinks the thermometer during the proceſs in a remarkable degree. If it is put into an air-pump, and the atmoſpherical preſſure be reduced to about nine inches of mercury, the carburetted ſulphur begins to aſſume the form of a gas; but upon reſtoring the common preſſure, this gas will immediately again reſume its liquid ſtate. It takes fire upon the application of a flame, and burns like alcohol, giving out at the ſame time a ſulphureous odour, and depoſiting both ſulphur and carbon. When kept for ſome time in a vial with atmoſpheric or azotic gaſſes, it is diſſolved by them in ſmall proportion, and renders them inflammable. It combines with nitrous gas, and the mixture burns like zinc. When diſſolved in oxygen gas, the reſult is an air that explodes with ſuch prodigious violence as to render it dangerous to ſet fire to even a few ounce meaſures at the ſame time. In the ſtate of vapour it combines ſlowly with the cauſtic fixed alkalis, forming with them deep amber-coloured ſolutions. By alcohol it is reduced to a ſoft paſty conſiſtence. It diſſolves very eaſily in cold olive oil, or in ether, depoſits a little charcoal, and then aſſumes a cryſtalline form.

Carbon is ſaid by Prouſt to be capable of uniting with phoſphorus, but this, from ſubſequent experiments, appears to be a miſtake.

Two of the metals are known to unite with charcoal; when combined with Iron the product is called ſteel; and with Copper it forms a peculiar ſubſtance, firſt noticed by Dr. Prieſtley, and named by him charcoal of copper.

The action of the alkalies upon charcoal has been but little examined into; it is certain, however, that cauſtic potaſh, by long digeſtion with this ſubſtance, becomes coloured and partly carbonated.

The undecompoſable acids appear to have no action on charcoal, but the decompoſable ones are deprived by it of their oxygen, either entirely or in part, and the charcoal is changed into carbonic acid; thus phoſphoric acid and charcoal yield, by ignition, phoſphorus and carbonic acid; ſulphuric acid and charcoal yield ſulphur, ſulphureous acid, and carbonic acid. If highly dried and finely pulveriſed charcoal is poured into recently prepared oxymuriatic acid gas; as ſoon as the two ſubſtances come into contact the charcoal becomes red hot, and falls to the bottom of the veſſel, like a ſhower of fire.

The neutral and earthy ſalts with decompoſable acids are remarkably changed at a red heat by charcoal: the others ſuffer no perceptible alteration. Thus the ſulphats are converted into ſulphurets, the nitrats become carbonats, while the muriats and fluats remain unchanged.

The metallic ſalts are all of them decompoſed by charcoal at a greater or leſs degree of heat, in conſequence of the deoxygenation of their baſes, independently of the action of this ſubſtance on their acids.

The effects of charcoal in clarification are both curious and important. They were firſt noticed by M. Lowitz of Peterſburg, and have for the moſt part been amply confirmed by ſucceeding obſervers, although the preciſe cauſe of theſe remarkable changes has not been ſatisfactorily aſcertained. All that is eſſential for this purpoſe is, that the charcoal ſhould be in fine powder and very dry; hence the only preparation requiſite is to pulverize ſome well burnt common charcoal, and then heat it in a covered crucible to a glowing red, till it ceaſes to give out an inflammable vapour. If it is not employed immediately, it ought to be kept in a ground ſtoppered glaſs bottle, and may then be preſerved unimpaired for any length of time. The effects of this prepared charcoal are very ſtriking. Being mixed with common vinegar, or any kind of wine, a thick froth riſes to the ſurface, and the liquors, after filtration, are found to be as limpid as water. The filthieſt and moſt putrid ditch-water is in like manner rendered perfectly clear, inodorous and inſipid; and rancid oils are alſo deprived of their ſmell and taſte by repeated filtration through this prepared charcoal. Hence alſo its peculiar efficacy as a dentrifice; it is ſufficiently hard to remove the concretions from the teeth without injuring the enamel, while it neutralizes and entirely deſtroys for a time any fœtor which may ariſe from a carious tooth.

### § 2. *Of carbonous oxyd, or gaſſeous oxyd of carbon.*

Dr. Prieſtley was the firſt perſon who effectually called the attention of chemiſts to this ſubſtance; but for a correct acquaintance with its nature and properties we are indebted to Mr. Cruickſhank. It had always been objected by Dr. Prieſtley, againſt Lavoiſier's hypotheſis of the conſtitution of fixed air, that when charcoal, however dry, was diſtilled with ſcales of iron, or the red oxyd of mercury, the product was not only carbonic acid, but a large quantity of a heavy, inflammable air, reſembling, in many reſpects, carburetted hydrogen, and ſuppoſed by Dr. Prieſtley to be actually this very gas. Now carburetted hydrogen conſiſts of hydrogen, holding carbon in ſolution; and if it were really produced by the mutual action of carbon and a metallic oxyd, could only be accounted for upon the Lavoiſerian theory by the caſual preſence of ſome water. But the gas is produced in ſuch great abundance, even when the materials have ſeparately been firſt expoſed to a very high heat to drive off every atom of water, that this hypotheſis is untenable; it is, therefore, an obligation of no trifling kind that the modern chemical theory is under to Mr. Cruickſhank, for having ſhewn that this gas, though inflammable, does not neceſſarily contain any hydrogen whatever, but has only a ſimple combuſtible baſe, namely, carbon, and differs from carbonic acid merely by its ſmaller proportion of oxygen. Hence, it is properly called an oxyd of carbon, and bears the ſame analogy to carbonic acid as the nitrous oxyd does to the nitric acid. The experiments of Mr. Cruickſhank have been repeated with much apparent accuracy by Meſſrs. Clement and Deſormes, and the reſults obtained by them correſpond very nearly with thoſe of the former chemiſt.

The gaſſeous oxyd of carbon may be produced either by the partial oxygenation of carbon, or the partial deoxygenation of carbonic acid, or the ſolution of carbon in carbonic acid, on each of which methods we ſhall proceed to ſay a few words.

The original experiment by Dr. Prieſtley is the following. Equal parts of ſcales of iron and charcoal (each having previouſly been ignited in ſeparate veſſels), were put into a glazed earthen retort and ſtrongly heated. In a ſhort time a prodigious quantity of air came over, which, on examination, was found to conſiſt of one tenth carbonic acid, and the remainder was "an inflammable air of a very remarkable "kind, being quite as heavy as common air. The reaſon "of this," Dr. Prieſtley adds, "was very apparent, when "it was decompoſed by dephlogiſticated air, for the greater "part of it was fixed air." The above two important properties, namely, the weight of this gas and its almoſt total convertibility into carbonic acid by oxygen, are fully confirmed by ſubſequent experiments.

Mr. Cruickſhank, in repeating this experiment of Dr. Prieſtley, found, that as ſoon as the retort was red, abundance of gas came over, which, being examined at different periods, was found, in the beginning of the proceſs, to be compoſed of one part of carbonic acid and four of carbonous oxyd, with a ſmall admixture of carburetted hydrogen; after this, to the end of the proceſs, the proportion of carbonous oxyd gradually increaſed to about ſix-ſevenths of the whole. Two ounces of the materials afforded many gallons of the gas.

The ſublimed oxyd of zinc was next ſubſtituted to the iron ſcales, and diſtilled in the ſame manner with charcoal. Even before the retort became red much gas was given out, and, on increaſing the heat, it came over in torrents. It contained a much ſmaller proportion of carbonic acid than the former, and, towards the end, conſiſted of pure oxyd of carbon. Part of the zinc was found, in the metallic ſtate, ſublimed into the neck of the retort. In like manner litharge, the grey oxyd of manganeſe, and the red oxyd of copper, produced with charcoal, firſt, a mixture of carbonic acid with carbonous oxyd, and, at laſt, the inflammable gas in a ſtate of purity.

The diſtillation of charcoal and the ſublimed oxyd of zinc was repeated by Clement and Deſormes, with particular attention to the quantity of products from a given weight of materials. The charcoal and zinc were firſt heated ſeparately, and examined. Common charcoal, when heated ſtrongly, gave a conſiderable quantity of inflammable gas, and about $\frac{1}{20}$th of its weight of water. After an hour nothing further came over; ſo that, to enſure the purity of the charcoal, it ſhould be uſed hot from the crucible or other veſſel in which it has been expoſed to a full red heat for half an hour. The oxyd of zinc gave out nothing at all by being heated *per ſe*; ſo that it may at any time be conſidered as pure, when previouſly free from accidental moiſture.

It was found, by experiment, that 14.36 parts of zinc increaſed, by calcination, to 17.48 of white ſublimed oxyd; and hence it is inferred that 100 parts of white oxyd conſiſt of 82.15 metal, and 17.85 oxygen. Pure charcoal, prepared as above, was mixed, to the amount of 30 grammes, (463 grains) with an equal weight of oxyd of zinc, which were put into a coated glaſs retort, communicating with lime-water, through which all the gaſeous products paſſed. When firſt heated, a ſmall portion of carbonic acid gas appeared, rendering the lime-water turbid; but this ſoon ceaſed, and the gas was purely inflammable. In five hours the production of gas had entirely terminated, and the total products of the operation were as follows:

| | Grammes. |
|---|---|
| Zinc ſublimed in the retort - - - | 21.82 |
| Charcoal remaining - - - - | 26.60 |
| Carbonic acid - - - - - | 0.07 |
| Nine litres (16.9 wine pints) of inflammable gas | 10.35 |
| | 58.84 |
| Loſs - | 1.16 |
| | 60.00 |

In all the preceding experiments the carbonous oxyd was obtained by the partial deoxygenation of the metallic oxyds and the conſequent oxygenation of the carbon. In thoſe which we are about to relate, the ſame gas was procured by inverting the proceſs, that is, by depriving carbonic acid of a portion of its oxygen.

Dr. Prieſtley, having obtained an inflammable gas, by heating together carbonat of barytes and magnetic oxyd of iron, Mr. Cruickſhank was induced to vary the experiment in the following manner. Equal parts of chalk (heated red hot previouſly for ten minutes), and of iron filings were mixed together, and heated in an earthen retort, abundance of gas was given out, conſiſting pretty uniformly of one part carbonic acid and five of carbonous oxyd.

An ounce of chalk previouſly heated red for ten minutes, was mixed with an equal weight of zinc filings, and heated gradually in a coated glaſs retort. A little carbonic acid came over at firſt, but mixed with oxyd of carbon; and when the contents of the retort were thoroughly red, nothing but the inflammable gas came over, and that in prodigious quantity. It was examined at different periods of the diſtillation, and proved to be wholly unmixed with carbonic acid. After the proceſs, the retort being examined, there was found ſome ſublimed oxyd of zinc in its neck, below which was ſome metallic zinc, and at the bottom was a mixture of oxyd of zinc, and partly cauſtic lime. Chalk, with tin filings, gave a ſimilar reſult.

In theſe experiments, the carbonic acid was united to an earthy baſe before diſtillation, and conſequently was expoſed to the deoxydating effect of the metallic filings in its naſcent ſtate, or, at the moment of its aſſuming the gaſeous form, a ſtate in which airs of all kinds are peculiarly ſuſceptible of chemical change. Mr. Cruickſhank found, however, that carbonic acid, even in the elaſtic ſtate, was alſo ſuſceptible of being deoxydated by the ſame means, though not quite ſo eaſily. For this purpoſe, ſome dry chalk was introduced into an iron retort, over which was rammed ſome dry ſand, and a ſtratum of iron-filings over all. In this arrangement, the carbonic acid gas expelled from the chalk had to traverſe a ſtratum of ſand three inches thick, before it could reach the iron-filings. The gaſeous products of the diſtillation were a quantity of undecompoſed carbonic acid, together with a large proportion of the inflammable gas, and the iron filings were taken out conſiderably oxydated. The decompoſition of carbonic acid by metals does therefore take place, when the acid is in the gaſeous form, but by no means ſo perfectly as when in its naſcent ſtate. A ſimilar decompoſition was alſo effected by forcing the ſame carbonic acid gas ſucceſſively backwards and forwards through an iron tube, the middle of which was full of iron-filings, and kept red hot by a ſmall furnace placed beneath it. A bladder was tied to each end of the tube to receive the gas, and, by paſſing it twenty times ſlowly through the tube, two thirds of it were converted into inflammable gas.

It is obvious, that if to any baſe, already united with oxygen, we add a freſh portion of the baſe, it will have the ſame relative effect as abſtracting part of the oxygen; and this offers another mode of preparing carbonous oxyd, which has been ſucceſsfully practiſed by Meſſrs. Clement and Deſormes. Pelletier had previouſly diſcovered that though the native carbonat of barytes is ſcarcely calcinable, *per ſe*, in any fire, yet it will readily part with its acid by calcination, if previouſly ground to fine powder, and mixed with a little charcoal. The chemiſts above-mentioned, on repeating this experiment with three parts of carbonated barytes and one of charcoal, obtained a large quantity of gas, compoſed of about $\frac{5}{6}$ carbonous oxyd, and $\frac{1}{6}$ carbonic acid, and the barytes remaining in the retort was found to be quite cauſtic. Here, therefore, it is to be ſuppoſed, that the carbonic acid is ſuperſaturated with its own baſe, and thus rendered much more volatile than before.

A more direct combination of carbon with carbonic acid was alſo obtained by the two aſſociated chemiſts juſt mentioned, with preciſely the ſame apparatus as that uſed by Mr. Cruickſhank for paſſing carbonic acid gas over red hot iron, except that the tube was filled with pulverized charcoal inſtead of iron-filings. The firſt ſenſible effect produced on the gas was a conſiderable dilatation, excluſive of the mere expanſion by heat, and ariſing from the ſolution of a part of the heated charcoal in the gas as it paſſed over. After each experiment, by far the greater part of the carbonic acid was changed into the inflammable gaſeous oxyd of carbon, the reſidual carbonic acid not amounting to more than from $\frac{1}{10}$th to $\frac{1}{30}$th of the whole. The remaining charcoal being taken out and weighed was found to be conſiderably diminiſhed; but the proportional loſs was uniformly greater in tubes of iron, than of glaſs or porcelain, doubtleſs on account of part of the carbon being combined with the iron, and thus converting it internally into ſteel. The compoſition of the gaſeous oxyd, into which the carbonic acid was changed, calculated from the amount of charcoal taken up by it in porcelain tubes, appears to be about 53 of oxygen, and 47 of carbon.

The properties of pure carbonous oxyd, prepared from chalk or carbonat of barytes, and filings of iron or zinc, are the following. It is lighter than atmoſpheric air, in the proportion of 22 to 23. Hence, its ſpecific gravity (that of water being 1000), will be 1.177, while that of atmoſpheric air is 1.2308; hence, it materially differs from carburetted hydrogen, the weight of which is not more than half that of common air. It ſuddenly deſtroys animal life.

It is in no degree altered by being electrized, *per ſe*, for a conſiderable length of time. It burns in the open air with a quiet, blue flame. When previouſly mixed with common air and kindled, it does not explode but burns ſlowly: when mixed with oxygen gas, and fired by the electric ſpark it explodes, but not very violently, and gives out a red flame. If a ſmall jet, communicating with a reſervoir of this gas, be ſet fire to, and introduced into a large balloon receiver filled with oxygen gas, it is found to burn brightly for a time, and afterwards goes out. The gas remaining in the receiver is not greatly diminiſhed, and the inſide of the veſſel, though ſomewhat damp, is by no means ſtudded with thoſe viſible drops of liquid that characterize the combuſtion of hydrogen. The reſidual gas, on examination, will be found to conſiſt of carbonic acid with ſome uncombined oxygen.

The relative proportions of carbonous oxyd and oxygen requiſite to mutual ſaturation, and the conſequent production of carbonic acid, are the means of aſcertaining the exact conſtituent parts of this inflammable gas. When 20 meaſures of pure gaſeous oxyd are mixed with eight meaſures of oxygen and exploded, the whole is reduced to 18 or 19 meaſures, and is entirely abſorbable by lime-water; it is, therefore, carbonic acid. The weight alſo of this latter product is found to correſpond, as nearly as can be expected in experiments of this kind, with the ſum of the weight of its two ingredients before mixture. One hundred cubic inches of carbonous oxyd with 40 inches of oxygen produce 92 cubic inches of carbonic acid, and the weight of the firſt may be eſtimated at 30 grains, of the ſecond at 13.6, and of the third at 43.2; the ſum of the two firſt differing from the third only by 0.4 of a grain.

Hence it may be inferred, that 100 parts, by meaſure, of gaſeous oxyd of carbon, require for ſaturation 40 meaſures of oxygen gas, and produce, by combuſtion, about 92 meaſures of carbonic acid gas; or, by weight, that 100 grains of carbonous oxyd require about 45.5 grains of oxygen, and are converted into 144 grains of carbonic acid, 1.5 grain being allowed for water and caſual impurities. Now carbonic acid has been found by Lavoiſier and other chemiſts to conſiſt of 28 parts, by weight of carbon, and 72 of oxygen; conſequently 144 grains of carbonic acid (the product of the full oxygenation of 100 grains of the inflammable gas), contain 40.32 grains of carbon; therefore the remainder of the 100 grains of the oxyd, i. e. 59.68 grains, muſt be oxygen. Hence, carbonous oxyd may be ſtated as compoſed of

40.32 carbon
59.68 oxygen

100.00

Or, by another calculation, 144 grains of carbonic acid contain 72 per cent., or 103.68 grains of oxygen; but only 45.33 grains of oxygen were added to the inflammable gas to produce this carbonic acid, and, conſequently, the difference between 103.68 and 45.33, or 58.35 grains of oxygen were already contained in the gas, leaving 41.65 grains, to complete the 100 grains of this gas, for carbon: hence, according to this calculation, carbonous oxyd conſiſts of

41.65 carbon
58.35 oxygen

100.00

We may, therfore, reckon on an average, that 100 grains of carbonous oxyd, obtained from the decompoſition of the earthy carbonats by metallic ſubſtances in its pureſt poſſible ſtate, unmixed with any hydrogen, are compoſed of about 41 of carbon and 59 of oxygen.

A true combuſtion of the gaſeous oxyd of carbon takes place when it is mixed with oxymuriatic acid gas. If the latter be recently made and added to carbonous oxyd in due proportion, the whole mixture is converted into carbonic acid and ſimple muriatic acid; the carbonous oxyd having been fully oxygenated by the exceſs of oxygen in the oxymuriatic acid. The proper proportions for the complete ſucceſs of this experiment are two meaſures of carbonous oxyd, and $2\frac{2}{3}$ meaſures of oxymuriatic acid. A mixture, thus proportioned, being kept for 24 hours in a ground ſtoppered vial, and, for further ſecurity, inverted in mercury, when opened in water will undergo an inſtantaneous abſorption of about two-thirds, which is muriatic acid gas; the reſidue, by agitation with lime-water, will be taken up, with the exception of about $\frac{1}{10}$th, which is a caſual mixture of azot.

Oxyd of carbon, when heated with phoſphorus, diſſolves a portion, and then burns with a pale yellow flame. The phoſphorus is neither depoſited nor acidified by long ſtanding, even when aſſiſted by water.

The effect of hydrogen on the carbonous oxyd is very ſtriking. When equal parts of theſe gaſſes are mixed together and paſſed through a glaſs tube made red hot, a complete decompoſition takes place, the gaſeous oxyd depoſits its charcoal on the inſide of the tube, which, being nearly melting, cauſes it to adhere, and to form a brilliant, uniform, black enamel; while the oxygen of the gaſeous oxyd by union with the hydrogen forms water, which is condenſed at the further end of the tube. Some of the hydrogen paſſes through apparently unaltered.

The decompoſition of carbonic acid gas, by means of electricity, when in contact with mercury or any other eaſily oxydable metallic body, well illuſtrates the nature of carbonous oxyd. Dr. Prieſtley was the firſt who found a change to take place in carbonic acid gas by taking the electric ſpark in it repeatedly for a conſiderable time. Out of many experiments, the following may be ſelected. In a ſmall tube containing about $\frac{1}{15}$th of an ounce meaſure of carbonic acid, and ſtanding over mercury, the electric ſpark was taken for the ſpace of an hour; after which the whole tube was clouded by a pulverulent matter of a black colour in the upper part of the tube, but yellow at the bottom, like ſulphur. This ſubſtance, on examination, proved to be oxyd of mercury. The air itſelf was a little enlarged, and about a fifth part of it was rendered inſoluble in water.

The elegant experiments of Th. de Sauſſure have thrown much light on this ſubject. Electric ſparks were taken for 18 hours in a glaſs tube containing 13 cubic inches of dry and pure carbonic acid gas and confined by mercury. After electrization much black oxyd of mercury was diſcovered; a very ſlight dilatation amounting to no more than $\frac{1}{10}$th of a cubic inch was obſerved. On throwing up ſome cauſtic alkali no more than one cubic inch was abſorbed, which was therefore carbonic acid; the next was very pure oxyd of carbon, for where 100 parts of it were burnt with about a third of oxygen gas no water was perceived, the product being merely carbonic acid.

Carbonic acid has alſo been decompoſed by the ſame ingenious chemiſt by hydrogen, by aid of the electric ſpark. In a long glaſs tube were mixed together $3\frac{3}{4}$ meaſures of pure carbonic acid with an equal quantity of hydrogen, and the whole was electrized for twelve hours. A condenſation took place, conſiderable at firſt, but very trifling towards the concluſion of the proceſs. A number of fine drops of water were depoſited on the upper part of the tube, and the gaſeous mixture was reduced in bulk from $7\frac{1}{4}$ meaſures to $4\frac{3}{4}$, of which one was undecompoſed carbonic acid, and the remaining $3\frac{3}{4}$ were carbonous oxyd, containing a ſmall admixture of hydrogen. In the above experiment the hydrogen appears to unite with part of the oxygen of the carbonic acid, to form the water, which is condenſed, while the carbonic acid, by loſing oxygen, paſſes to the ſtate of carbonous oxyd.

A ſimilar decompoſition of carbonic acid by hydrogen alſo takes place when the mixed gaſſes are paſſed through a red hot porcelain tube, and the gaſeous oxyd is produced.

### § 3. *Of hydrocarbonat, or carburetted hydrogen.*

In the former ſection we have treated of the combination of carbon with a leſs portion of oxygen than is required for its acidification; in the preſent ſection we ſhall examine the phenomena attending the combination of carbon with hydrogen. Carburetted hydrogen, otherwiſe called *heavy inflammable air*, is an inflammable gas conſiderably heavier than hydrogen, but lighter than carbonous oxyd, or common air: it does not render lime-water turbid, when agitated with it, and by combuſtion with oxygen is totally reſolvable into carbonic acid and water.

Before it was ſuſpected that carbon could exiſt in any other ſtate of oxygenation than carbonic acid, it might be inferred, with tolerable though not abſolute certainty, that when any gas had been purified from carbonic acid by means of alkali or lime-water, if it furniſhed a freſh portion of this acid after combuſtion with oxygen, the carbonaceous ingredient exiſted in the ſtate of pure carbon or charcoal. Therefore, as the only products of carburetted hydrogen, when burnt with oxygen, are carbonic acid and water, chemiſts generally ſatisfied themſelves with eſtimating the quantity of carbon contained in the gas, by taking about 28 per cent. of the carbonic acid produced, and ſet down the entire remainder as hydrogen. For example, if 100 cubic inches of any gas, weighing 15 grains, were totally reſolvable into carbonic acid and water, by combuſtion with oxygen; and if, by the combuſtion, 54 inches of carbonic acid, weighing 25 grains, were produced, the quantity of carbon originally contained in the gas would be reckoned to be ſeven grains, (being 28 per cent. of the weight of the carbonic acid,) and the difference between 7 and 15, or eight grains would be conſidered as the weight of the hydrogen; or, in other words, the gas would be called a carburetted hydrogen, conſiſting of hydrogen holding carbon in ſolution, in the proportion of eight, by weight, to ſeven of the latter.

But, it is obvious, that this mode of eſtimating muſt be totally erroneous in the caſe (probably very frequent), of a mixture of gaſeous oxyd of carbon and hydrogen gas; and hence no approach to analyſis can be obtained without aſcertaining both the water and carbonic acid produced, and even then various cauſes of uncertainty will occur.

So that it is poſſible, and by no means improbable, that there may exiſt three ſpecies of gaſſes, all of which have a claim to the title of hydrocarbonat, or carburetted hydrogen, namely, 1ſt. hydrogen, ſimply holding carbon in ſolution, or what correſponds with the original idea of a hydrocarbonate; 2d. hydrogen mixed with gaſeous oxyd of carbon; 3d. a mixture of the two former ſpecies, or hydrogen and gaſeous oxyd of carbon with an exceſs of carbon held in ſolution by one or both of theſe gaſſes.

Carburetted hyrogen is obtained in a great variety of ways, and with very conſiderable differences in ſpecific gravity and the proportion of ingredients. It is found native on the ſurface of ſtagnant waters, marſhes, wet ditches, &c. through which, if examined cloſely, large bubbles will be ſeen to riſe in hot weather, and may be increaſed at pleaſure by ſtirring up the bottom with a ſtick. In cloſe, ſtill evenings, if a candle be held over the ſurface, flaſhes of a blue lambent flame may be perceived ſpreading to a conſiderable diſtance. All that is not fabulous in the *ignis fatuus* is probably derived from this ſource. This ſpecies may be termed, for diſtinction, the carburetted hydrogen of marſhes: in the pureſt form in which it can be collected it is uſually mixed with about 20 per cent. of azot.

This gas is alſo given given out very abundantly by almoſt every vegetable ſubſtance that is expoſed to a dry heat ſufficient for its decompoſition. When heated in cloſe veſſels much more hydrocarbonat is obtained than by combuſtion in the open air, the product in this latter caſe containing more carbonic acid. It would be endleſs to enumerate the vegetable ſources of this gas, but we ſhall mention ſome of the moſt convenient modes of obtaining it in a ſtate of purity.

One of the commoneſt methods employed is the deſtructive diſtillation of the acetous ſalts. For this purpoſe, let a ſmall proportion of dry acetite of potaſh be heated in a glaſs retort. The ſalt ſoon melts in its water of cryſtallization, puffs up, and, if the retort is too ſmall, is very apt to come over into the neck. The firſt products are water and the air of the veſſels; but, when the acetous acid begins to be ſcorched, a large ſtream of gas begins, and continues till the whole is red hot, and little elſe remains in the retort but carbonated alkali and a little charcoal. Along with the gas there ariſes much oil, which is condenſed in the cool receiver. The gas, according to the analyſis of it by Dr. Higgins, after the firſt portions have paſſed over, conſiſts of nothing but hydrocarbonat and carbonic acid, which laſt may be ſeparated by lime-water. The hydrocarbonat itſelf varies conſiderably. The firſt part is much heavier than the laſt, (though ſtill lighter than common air,) and appears to hold in ſolution part of the oil; for, on ſtanding ſome time over water, it becomes lighter, and is found to require leſs oxygen for ſaturation than before. The average ſpecific gravity of the firſt and laſt gas mixed is to that of common air as two to three.

Carburetted hydrogen is obtained in great purity by ſending the vapour of imflammable vegetable matter through an earthen or glaſs tube paſſing through a furnace, and kept red hot in the middle. The vapour of camphor, ether, alcohol, and other inflammables thus treated, is converted into this gas, but with much difference in quantity, according to the degree of heat and other circumſtances.

Another method of obtaining carburetted hydrogen, is to put coal, wood, peat, &c. into any convenient veſſel, an earthen or iron retort for example, and heat it ſlowly to redneſs.

Moſt animal inflammable ſubſtances, ſuch as ſilk, fat, wax, and the like, yield this gas as freely as vegetable matter, by a ſimilar treatment. This was diſcovered by Berthollet, in his maſterly reſearches on the nature of animal matter and ammonia.

Carburetted hydrogen (or at leaſt a gas that gives water and carbonic acid by combuſtion with oxygen), is alſo generated in abundance, when charcoal, without previous drying, is heated *per ſe* in cloſe veſſels, and continues to be given off till the charcoal has been in a ſtate of full ignition for about an hour; after which it ceaſes, and the charcoal, as already mentioned, is rendered pure. A ſimilar proceſs of obtaining this

this gas, is to incloſe powdered charcoal in a tube paſſing through a furnace, to confine the charcoal by a pellet of clay looſely fixed at each extremity of the tube, and in that ſituation to ſend through it the vapour of water kept boiling in a ſmall retort attached to one end of the tube. Much carbonic acid gas is generated this way, and, when this is ſeparated by lime-water, the reſidue is inflammable.

Laſtly, this gas may be procured by the direct union of its conſtituent parts. If hydrogen gas is paſſed ſeven or eight times ſucceſſively through an iron tube containing charcoal, and heated red-hot, a diminution of bulk takes place, the hydrogen diſſolves a portion of the charcoal, and then aſſumes the properties of carburetted hydrogen.

A curious variety of hydrocarbonous gas, was diſcovered by the aſſociated Dutch chemiſts (Van Dieman, Trooſtwyck, and others) which is procured from ether or alcohol, and has the remarkable property of generating an oil when mixed with oxymuriatic acid gas. Hence it has been termed *oily carburetted hydrogen*, or *olefiant gas*. The mode of preparing this ſingular gas, and the enumeration of its diſtinguiſhing properties, will form the ſubject of the next ſection; it may, however, be obſerved here, that according to Mr. W. Henry's experiments, the olefiant gas appears alſo to be contained in part in the hydrocarbonat from coal, wax, and ſome other ſubſtances, and greatly to contribute to the quantity of light and heat which theſe gaſſes give out as well as to their large proportion of carbonic acid.

Carburetted hydrogen is ſingularly affected by the electric ſpark. Dr. Auſtin found, that on taking the electric ſpark repeatedly through this gas, obtained from acetite of potaſh, the bulk of the gas enlarged after every ſhock, and at length expanded to nearly twice its original dimenſions. When examined after this expanſion, it was found to be as inflammable as before, and judging from the teſt of lime-water no carbonic acid appeared to have been generated. Dr. A. concludes that the enlargement can only be owing to the production of a quantity of hydrogen, and makes ſome inferences which, however, have ſince been ſhewn by Mr. W. Henry to be erroneous. Mr. H. demonſtrates that there is no deſtruction of carbon by this proceſs, ſince the ſame quantity of carbonic acid is produced after as before electrization by the action of oxygen gas. He likewiſe makes it appear probable, that the water held in ſolution by the gas is the chief agent in its expanſion, ſince when the gas has been dried by cauſtic alkali no continuance of electrization will enlarge it more than one ſixth of its original bulk; but when the contact of water is admitted, the bulk is doubled by the ſame treatment. Perhaps the diſcovery of carbonous oxyd will explain this fact. It is not improbable that the carbon of the gas may unite with the oxygen of the water, and thus produce the carbonous oxyd which would not give any precipitate with lime-water, and the bulk of the gas would be enlarged both by the carbonous oxyd and the hydrogen of the water, as well as by the expanſion which the hydrocarbonat would undergo after the carbon was ſeparated from it, whilſt the actual quantity of carbon remaining the ſame, as much carbonic acid would be ſeparated by compleat oxygenation as before electrization. It is not improbable that the affinities of hydrogen and carbon for oxygen are ſo nearly equal, that either ſubſtance is able *partially* to decompoſe the complete oxyd of the other. Thus we find, that when hydrogen and carbonic acid are together ſubjected to electricity, the carbonic acid is partially decompoſed, and the product is carbonous oxyd and water, and on the other hand, when water is decompoſed by red hot charcoal, a part of the product is alſo the carbonous oxyd.

All the hydrocarbonats are fatal to animal life; not at appears from the mere abſence of oxygen, but from the preſence of ſomething poſitively noxious: ſince animals immerſed in it die ſooner than they would from the mere interruption of reſpiration.

This gas is ſcarcely if at all abſorbed by water, but by long ſtanding over it depoſits a part of its carbon. This, however, applies only to thoſe hydrocarbonats that require at leaſt their own bulk of oxygen to ſaturate them, and eſpecially to that variety called olefiant gas.

Simple carburetted hydrogen, when ſet fire to, burns at the ſurface in contact with the air with a blue flame with red edges, but when mixed with any of the olefiant gas the flame becomes much more brilliant, reſembling that of oil. When applied to the purpoſes of illumination the hydrocarbonat from coal, from lamp-oil, or from wax, produces as much light in an Argand lamp as oil in ſubſtance does; this appears to be owing to the olefiant gas which they contain. The brightneſs of the flame is much diminiſhed when theſe gaſſes have been kept over water, and hence for illumination they ſhould be uſed as ſoon as prepared.

The combuſtion of hydrocarbonat is much more brilliant in oxygen gas, and the products if a ſufficient quantity of oxygen has been uſed, are merely water and carbonic acid.

If any of the hydrocarbonats be mixed with oxygen gas and fired in a cloſe veſſel by the electric ſpark, or in any other way, an exploſion takes place more or leſs violent according to the quantity of carbon contained in the gas, and the reſult of the decompoſition is carbonic acid, together with any unconſumed gas or exceſs of oxygen, while the water is found condenſed in drops on the ſides of the jar. A ſingle cubic inch of the mixed airs is generally as much as can be conveniently managed at each exploſion, and when any olefiant gas is preſent even this ſmall quantity will endanger very thick glaſs jars; a very vivid red flame appears at the moment of exploſion, and a great inſtantaneous enlargement takes place, after which the bulk is ſuddenly reduced to much leſs than its original quantity. When the carbonic acid is abſorbed, if the gaſſes have been properly proportioned, no gaſeous reſidue is left except accidental impurities.

The oxymuriatic acid furniſhes alſo a very uſeful method of decompoſing and analyſing all the hydrocarbonats. Mr. Cruickſhank's beautiful and accurate experiments on this ſubject are highly inſtructive. The oxymuriatic acid gas was procured from oxymuriat of potaſh, by means of muriatic acid, and was uſed ſoon after being prepared, as it is in ſome degree altered by keeping.

Pure hydrogen and oxymuriatic acid gas were firſt tried; one meaſure of the former with two of the latter mixed in a glaſs vial with a ground ſtopper, and inverted over water were ſuffered to remain 24 hours. The ſtopper being then withdrawn, the water ruſhed into the vial, abſorbing the whole of its gaſeous contents, except about $\frac{1}{30}$ of the whole, which was azot, and doubtleſs a caſual impurity.

The different hydrocarbonats were then tried. In a bottle filled with, and inverted over water, one meaſure of well waſhed hydrocarbonat from camphor was mixed with two of oxymuriatic acid. A ſlight cloud and trifling abſorption were perceived at the time of mixture, after which the ſtopper was put in, and the whole was left at reſt for 24 hours. When opened under water all the gas was abſorbed, except 0.43 of a meaſure, and this was reduced by lime-water to 0.34. This reſidue was ſtill inflammable, but burnt with a lambent blue flame like carbonous oxyd; and this it was proved for the moſt part to conſiſt of, by the large quantity of carbonic acid which it yielded when fired with oxygen; two parts of it with one of oxygen yielding no leſs than 1.7 of carbonic acid.

In the above experiment the mutual decompoſition of the oxymuriatic acid and carburetted hydrogen, produces no leſs than four new compounds: namely, common muriatic acid by the loſs of oxygen; water by the union of oxygen with hydrogen; carbonous oxyd by the partial oxygenation of ſome of the carbon; and carbonic acid by the compleat oxygenation of the remainder.

On increaſing the quantity of oxymuriatic acid to about four times that of the carburetted hydrogen, the whole of the carbon was now found to be completely oxygenated, and every thing was abſorbed by water or lime-water; the products were therefore only muriatic and carbonic acids and water.

Mr. Cruickſhank found a very conſiderable difference in the quantity of carbonic acid produced, and of courſe in the carbonaceous ingredient in the hydrocarbonats from camphor, ether, and alcohol, when they had been long kept over water or agitated with it. A ſimilar difference in the quantity of combuſtible matter was obſerved by Dr. Higgins, in the hydrocarbonat from acetite of potaſh, which renders it highly probable that theſe hydrocarbonats hold in ſolution ſomewhat of an oily ethereal vapour, or a portion of true olefiant gas which water will abſorb. This alſo, it probably is, which cauſes the ſlight diminution which ſome of the hydrocarbonats *immediately* experience when mixed with oxymuriatic acid gas; for with pure olefiant gas the diminution is great and immediate, as we ſhall preſently mention. When oxymuriatic acid gas and carburetted hydrogen are mixed in the proportion of two of the former to one of the latter, and the mixture is exploded by the electric ſpark, a copious depoſition of charcoal takes place, but when oxymuriatic acid gas is uſed in a larger quantity, the whole of the carbon is converted into carbonic acid. This ſeparation of charcoal takes place only with the hydrocarbonats from camphor, ether, and alcohol, and even in theſe this property is loſt by being kept ſome time over water.

Carburetted hydrogen is alſo readily decompoſed by ſulphur; the carbon being precipitated in form of a black powder, and the hydrogen uniting by preference with the ſulphur forming hepatic gas. This may be moſt conveniently effected by making ſulphur red hot in an earthen tube and then paſſing the carburetted hydrogen through it.

### § 4. *Of olefiant gas.*

The diſcovery of this ſingular ſpecies of carburetted hydrogen is due to ſome aſſociated chemiſts of Amſterdam, (Van Dieman, Van Trooſtwyck, Bondt, and Lawrenburgh,) and originated in their examination of the different products of the diſtillation of ſulphuric acid and alcohol, in the preparation of ether. In the common proceſs this gas appears towards the latter end of the diſtillation accompanied by the *oil of wine;* but in order to procure it immediately, for the purpoſe of experiment, nothing more is neceſſary than to put into a proof bottle a little rectified alcohol, and four times its weight of ſtrong ſulphuric acid; much heat is given out on mixture; the colour becomes firſt brown, and then black, and on the application of a gentle heat the gas in queſtion is produced in vaſt abundance, and may be collected in jars inverted over water. The only foreign matters with which the gas is mixed are ſulphureous acid, and a little ether, but theſe may be got rid of by waſhing it with ſome very dilute liquid ammonia, and then the olefiant gas remains pure.

When thus prepared it exhibits the following properties. Its ſpecific gravity is to that of atmoſpheric air, as 905 to 1000. Its odour is very fetid. It burns with a denſe flame, like an oil or reſin. It is not abſorbed nor altered by water, nor is it affected by any of the common reagents, whether gaſſes, alkalies, or acids, except the oxymuriatic acid gas. Equal parts of theſe gaſſes being mixed together, an immediate diminution of bulk takes place, a viſible vapour fills the veſſel, much heat is given out ſo as to be very ſenſible even to the hand, and at the ſame time a thick pearl-coloured oil appears in drops on the ſurface of the water, over which the mixture is made, and immediately ſinks to the bottom.

It is from this ſingular production of denſe oil, with the oxymuriatic acid, that this ſpecies of carburetted hydrogen has acquired the name of *olefiant* or *oil making*. When theſe two gaſſes are mixed in the proportion of four of oxymuriatic acid to three of carburetted hydrogen, the whole is abſorbed, except accidental impurities.

The oil thus generated is heavier than water, whitiſh, and ſemi-tranſparent. By keeping it becomes yellow and limpid; its odour is highly fragrant and penetrating; its taſte is ſomewhat ſweet. It is ſparingly ſoluble in water, to which it communicates its peculiar odour. Cauſtic potaſh has no effect on the oil, but ſeparates the adhering muriatic acid and renders it more fragrant.

The conſtituent parts of olefiant gas appear to be only carbon and hydrogen, but it contains a larger proportion of the former than the common hydrocarbonats do. It is decompoſed by ſulphur like the other hydrocarbonats.

The combuſtion of this gas offers ſome curious circumſtances. When an Argand lamp is ſupplied with it inſtead of oil, the flame far exceeds every oil and hydrocarbonat in beauty and brilliance. When mixed with oxygen gas, and detonated by the electric ſpark, the exploſion is much more violent than that of common carburetted hydrogen. Mr. Henry found that a ſtrong glaſs tube was ſhattered with only 0.3 of a cubic inch of olefiant gas, and 0.17 of oxygen; but when the quantity of oxygen is conſiderably below that required, for the compleat ſaturation of this gas, only a very trifling exploſion is produced.

Another ſingular property of olefiant gas is the copious depoſition of charcoal, when it is mixed with a ſmall quantity of oxygen or oxymuriatic acid gas and kindled. After the mixture of the olefiant and oxymuriatic acid gaſſes, two or three minutes elapſe before the oil thus generated is entirely precipitated, but if this mixture is immediately ſet fire to there is no production of oil; but in its ſtead ſo copious a depoſition of charcoal takes place, that the whole veſſel is obſcured, as if it had been lined with lamp-black.

A ſimilar depoſition of carbon takes place when the olefiant gas is mixed with juſt enough of oxygen to begin the combuſtion. If two parts of the latter are mixed with 1½ of the former, and the mixture ſet fire to by the electric ſpark, a copious depoſition of carbon enſues.

The great exceſs of carbon contained in olefiant gas is alſo manifeſt from the large proportion of oxygen required for its ſaturation, amounting to 2.84 to one, eſtimating each by bulk.

Olefiant gas has alſo been procured by the Dutch chemiſts, above named, not only from alcohol and ſulphuric acid, but by paſſing the vapour of alcohol or ether through a red hot earthen tube. In this caſe, however, the olefiant gas appears to be mixed with a little carburetted hydrogen. It is remarkable, that if a glaſs tube be uſed inſtead of an earthen one, the gas is no longer olefiant, but only ſimple carburetted hydrogen; but if the glaſs tube is filled with either alumine or ſilex the ſame effect is produced as with the earthen tube; on the other hand, when lime either pure or carbonated, or magneſia, were ſubſtituted to the two other earths, the gas was common carburetted hydrogen.

The whole of this very intereſting part of chemiſtry requires further examination, eſpecially as far as regards the formation of carbonous oxyd.

Carbon, in reference to *Huſbandry* and *Gardening*, a matter obtained from different animal and vegetable ſubſtances, by means of a ſlow and confined combuſtion. This ſubſtance is charcoal in its pure ſtate; that which is commonly met with containing a portion of incombuſtible earth, and ſome ſaline matter in union with the carbon. See Carbon and Charcoal.

The author of the "Philoſophy of Agriculture and Gardening," remarks, "that when animal and vegetable bodies are burnt without the acceſs of air, that is, where their volatile parts are ſublimed, there remains a greater quantity of charcoal, a much greater in vegetable bodies than in animal ones. This is termed carbon by the French ſchool, when it is quite pure, and is now known to be one of the moſt univerſal materials of nature: and as vegetable bodies contain ſo much of it in their own compoſition, they may be ſuppoſed to abſorb it entire where they grow vigorouſly, eſpecially as it is a ſimple material: but they may poſſibly form it alſo from water and air within their own veſſels, when they are excluded from acceſs to it externally. The whole atmoſphere contains always a quantity of it in the form of carbonic acid, or fixed air; as is known by the ſcum which preſently becomes viſible on lime water when expoſed to the air, and which conſiſts of a reunion of the lime with the carbonic acid, which may therefore be ſaid to encompaſs the earth. The ſimplicity of carbon as an elementary ſubſtance was diſputed by Dr. Auſtin, who believed he had decompounded it. But Mr. Henry, by accurately repeating his experiments, has ſhown the fallacy or inconcluſiveneſs of them, as may be ſeen in the Philoſophical Tranſactions for 1797. And it is added that a further great reſervoir of carbon exiſts in lime-ſtone, in the form of carbonic acid; which when the ſtronger acid is poured on, the calcareous earth becomes a gas, acquiring its neceſſary addition of heat from that which is given out in the combination of the ſtronger acid with the lime. It alſo acquires its neceſſary heat when lime-ſtone is burnt, from the conſuming fuel, riſing in the form of gas, and is diſſipated in the air; and probably ſoon ſettles on the earth as it cools, as it is conſiderably heavier than the common atmoſphere. But the great ſource of carbon exiſts in the black earth which has been lately left by the decompoſition of vegetable and animal bodies; and is then in a ſtate fit to combine with azote or nitrogen, and with oxygen, when expoſed to thoſe two gaſſes, as they exiſt in the atmoſphere, and is thus adapted either to promote the generation of nitrous acid, or to form carbonic acid, and thus to aſſiſt vegetation. Moraſſes conſiſt principally of the carbonic recrements of vegetable matters, which are gradually decompoſed in great length of time into clay, with argillaceous ſand, ſuch as is found over coal beds, and ſome calcareous earth, as in marl, and laſtly, with ſome iron and foſſile coal. Theſe by elutriation are ſeparated from each other, and form the ſtrata of coal countries. In other places they remain intermixed, as they were probably produced from the decompoſition of vegetables and terreſtrial animals; and form what in books of practical agriculture is called a *loamy* ſoil, conſiſting of carbonic matter, ſand, and clay, with a portion of iron. It has always been obſerved, that this black garden mould, or earth produced from the recrements of vegetables, is capable of abſorbing a much greater quantity of putrid effluvia than either air or water, and probably of combining with its ammonia, and producing a kind of *hepar carbonis*, and thus facilitating vegetation. The practice of burying dead bodies ſo few feet below the ſurface is a proof of this; as the putrid exhalations from the carcaſe are retained, and do not penetrate to the ſurface. On the ſame account, the air over new ploughed fields has long been eſteemed ſalutary to invalids, or convaleſcents, as it probably purifies the ſupernatant atmoſphere. But it was not till lately known that carbon, or charcoal, abſorbs with ſuch avidity all putrid exhalations; if it has been recently burnt, and has not been already ſaturated with them: inſomuch that putrid fleſh is ſaid to be much ſweetened by being covered a few inches with the powder of charcoal, or even for being buried for a time in black garden mould; as putrid exhalations conſiſt chiefly of ammonia, hydrogen, and carbonic acid, and are the immediate products of the diſſolution of animal or vegetable bodies; they are believed to contribute much to vegetation, as whatever materials have conſtituted an organic body may again, after a certain degree of diſſolution, form a part of another organic body. The hydrogen and azote produce ammonia, which combining with carbon, may form an *hepar carbonis*, and by thus rendering carbon ſoluble in water, may much contribute to the growth of vegetables. It has been ſaid, that ſome moraſſes have prevented the animal bodies which have been buried in them from putrefaction; which may in part have been owing to the great attraction of the carbon of the moraſs to putrid effluvia, and in part, perhaps, to the vitriolic acid which ſome moraſſes are ſaid to contain in their conſtitution."

"Then here occurs," ſays the author, "an important queſtion. By what other means is the ſolid carbon rendered fluid, ſo as to be capable of entering the fine mouths of vegetable abſorbents? The carbon, which exiſts in the atmoſphere, and in lime-ſtone, is united with oxygen, and thence becomes ſoluble or diffuſible in water; and may thus be abſorbed by the living action of vegetable veſſels; or may be again combined by chemical attraction with the lime, which has been deprived of it by calcination. When mild calcareous earth, as lime-ſtone, chalk, and marble, has been deprived of its water, and of its carbonic acid by calcination, it becomes lime. Afterwards, when it is cold, if water be ſprinkled over it, a conſiderable degree of heat is inſtantly perceived, which is preſſed out by the combination of a part of the water with the lime; as all bodies when they change from a fluid ſtate to a ſolid one, give out the heat which before kept them fluid. At the ſame time, another part of the water which was added, is raiſed into ſteam by the great heat given out, as above mentioned, and the expanſion of this ſteam breaks this lime into fine powder, which otherwiſe retains the form of the lumps of lime-ſtone before calcination. But if too great a quantity of cold water be ſuddenly added, no ſteam is raiſed, and the lump of lime-ſtone retains its form, whence it happens, that ſome kinds of lime fall into finer powder, and are ſaid to make better mortar, if ſlaked with boiling water, than with cold. On this account, the lime which is deſigned to be ſpread on land ſhould previouſly be either laid in a heap, and either ſuffered to become moiſt by the water of the atmoſphere, or ſlaked by a proper quantity of water: otherwiſe, if it be ſpread on wet ground, or when ſo ſpread is expoſed to much rain, the heat generated will be diſſipated without breaking the lumps of lime into powder, which will then gradually harden again into lime-ſtone, diſappoint the expectations of the agricultor, and afflict him with the loſs of much labour and expence. When the powder of ſlaked lime, mixed with ſand and water, is ſpread on a wall, that part of the water which is not neceſſary for its imperfect cryſtallization, evaporates into the air, and the lime then gradually attracts the carbonic acid, which is diffuſed in the atmoſphere: but as he ſuppoſes this carbonic acid is diſſolved in the water, which is alſo diffuſed in the atmoſphere, the lime is perpetually moiſtened by this new acquiſition of water from the air, as that which before adhered to it, and had parted with its carbonic acid, evaporates. On which account, new built walls are months, and even years in drying, as they continue to attract water along with the carbonic acid from the air, which ſtands upon them in drops till the lime regains its original quantity of carbonic acid, and again hardens into ſtone, or forms a ſpar by its more perfect, or leſs diſturbed manner of cryſtallization. It is conſequently ſuppoſed, that the earth acquires carbon, both in a manner ſimilar to the above, by its attracting either the carbonic acid, or the water in which it is diffuſed, from the atmoſphere, and alſo by the ſpecific gravity of carbonic acid gas being ten times greater than that of common air: whence, there muſt be conſtantly a great ſediment of it on the ſurface of the earth, which in its ſtate of ſolution in oxygen and water may be readily drank up by the roots of vegetables. Another means by which vegetables acquire carbon in great quantity, may be from lime-ſtone diſſolved in water, which though a ſlow proceſs, occurs in innumerable ſprings of water, which paſs through the calcareous or marly ſtrata of the earth; as thoſe of Matlock or Briſtol in paſſing through lime-ſtone, and thoſe about Derby in paſſing through marl; and is brought to the roots of vegetables by the ſhowers which fall on ſoils where marl, chalk, lime-ſtone, marble, alabaſter, and fluor, exiſt, which include almoſt the whole of this iſland.

By this ſolution of mild calcareous earth in water, not only the carbon in the form of carbonic acid, not yet made into gas, but the lime alſo with which it is united, becomes abſorbed into the vegetable ſyſtem, and thus contributes to the nutriment of plants, both as ſo much calcareous earth, and as ſo much carbon.

And another mode may be by the union of this ſimple ſubſtance, with which all garden mould abounds, with pure calcareous earth into a kind of hepar, analogous to the hepar of ſulphur made with lime, which abounds in ſome mineral waters, and this is ſuppoſed to be the great uſe of lime in agriculture."

For the purpoſe of aſcertaining the probability of this mode of ſolution of carbon, the following experiment was made. "About two ounces of lime in powder was mixed with about as much charcoal in powder, put into a crucible, and covered with about an inch or two of ſiliceous ſand. The crucible was kept red hot for an hour, or longer, and then ſuffered to cool. On the next day water was poured on the lime and charcoal, which then ſtood a day or two in an open cup, and acquired a calcareous ſcum on its ſurface. And though it had not much taſte, except that of the cauſticity of the lime, yet on dropping one drop of marine acid into a tea ſpoonful of the clear ſolution, a ſtrong ſmell like that of *hepar ſulphuris* was procured, or like that of Harrowgate water, which evinced that the carbon was thus rendered ſoluble in water. Hence, the doctor ſuggeſts, that the ſulphureous ſmell of Harrowgate and Kiddleſton waters, and other ſimilar ſprings, may be owing to the union of the alkali of decompoſing marine ſalt, with the carbon of the earth they run through, and that this kind of water might thus poſſibly be uſed as a profitable manure in agriculture."

And a ſtill further method by which vegetable roots acquire it, is ſuſpected to be "by their diſuniting carbonic acid from lime-ſtone in its fluid, not its gaſeous ſtate, which the lime-ſtone again attracts from the atmoſphere, and conſolidates, and forms other matters included in the ſoil. Firſt, becauſe lime is believed by ſome agricultors, who much employ it, to do more ſervice in the ſecond year than the firſt, that is, in its mild ſtate, when it abounds with carbonic acid, than in its cauſtic ſtate, when it is deprived of it. Secondly, that the uſe of burning lime ſeems hence to be ſimply to reduce it to an impalpable powder, almoſt approaching to fluidity, which muſt facilitate the application of the innumerable extremities of vegetable fibres to this incalculable increaſe of its ſurface; which may thence acquire by their abſorbent power, the carbonic acid from theſe minute particles of lime, as faſt as they can recover it by chemical attraction from the air or water, or other inanimate ſubſtances in their vicinity. Thirdly, the hyperoxygenation of the perſpirable matter of the plants, which thence gives up oxygen gas in the ſunſhine, would induce us to believe that a great part of the carbon which furniſhes ſo principal a part of vegetable nutriment, was received by their roots in the form of carbonic acid; and that it becomes in part decompoſed in their circulation, giving up its oxygen; which thus abounds in the ſecreted fluids of vegetables from this ſource, as well as from decompoſed water, as is generally known. And laſtly, there is another way by which carbon is received into the vegetable ſyſtem, which is by its exiſtence in ſugar and in mucilage, both of which are taken up undecompounded, as appears by their preſence in the vernal ſap-juice, which is obtained from the maple and the birch, which like the chyle of animals, is abſorbed in its undecompounded ſtate by the roots of plants." This matter muſt of courſe be conſidered as one of the principal conſtituent parts of vegetables; and would ſeem to enter into, and accumulate in the conſtitutions of plants in proportion to their ſucceſſive growth. Some plants, however, take more into their compoſition than others, as from the reſult of chemical analyſis, a quantity almoſt equal to all their other component parts has been found in particular inſtances, as in *agaricus piperatus*, *clavaria aurea*, *agaricus*, *lycoperdon teſſellatum*; while in others, only a very ſmall portion."

Carbon, in *Geography*, a cape on the N. coaſt of Africa, in the Mediterranean, directly N. from Bougie.

CARBONACEOUS *Matter*, in *Agriculture*, that kind of earthy matter, that partakes of the nature of carbon, or in which it abounds. It is found that materials of this ſort are highly uſeful in promoting the growth of plants and of courſe may be uſed with advantage in the growth of different crops.

CARBONADE, or Carbonado, in *Cookery*, fleſh, fowl, or the like, ſeaſoned and broiled on the coals.

CARBONAT *of Ammonia*, *Sal Volatile*, or *Salt of Hartſhorn*, in *Chemiſtry*. This well known ſalt is always prepared for uſe by decompoſing muriat of ammonia by carbonate of lime, and is done in the following manner. Mix together two parts of dry chalk with one of muriat of ammonia in powder, put them into a proper ſubliming veſſel, and apply a graa gradual heat. A double decompoſition takes place; the carbonic acid of the chalk uniting with the ammonia, and riſing to the top of the veſſel, and the lime remaining behind in union with muriatic acid. By degrees the carbonat of ammonia, which riſes as a denſe white vapour, concretes on the top of the veſſel in a hard ſemi-tranſparent cake. The muriat of lime that remains, was formerly applied to little uſe, but ſince the diſcovery of its wonderful powers, as a freezing mixture when combined with ſnow, it may perhaps be made more valuable. The whole of the carbonat of ammonia is not obtained till after the veſſel has been kept for ſome time at a low red heat.

The above is the actual way of preparing this ſalt, but the combination of the two ingredients may be made for experiments which gives a very beautiful appearance. Fill a jar about half full of carbonic acid gas ſtanding over mercury, then throw up ammoniacal gas (obtained in the way mentioned under AMMONIA), and at the moment of contact, a very denſe white cloud of carbonat of ammonia will fill the jar, a ſudden and abundant abſorption will take place, and if the gaſes be pure and properly proportioned, the mercury will rapidly riſe, and fill the whole cavity, leaving only a pellicle of white ſaline matter attached to the ſide of the glaſs which is the ſolid ammoniacal carbonat. Some heat is alſo given out during this condenſation of the gaſes enough to be ſenſible to the hand placed on the outſide of the jar. To make the mixture of the gaſes ſudden, the ammoniac ſhould be added to the carbonic acid gas; for the former, being by much the lighteſt, then traverſes the whole of the latter, and riſes with it; but if this order is inverſed and the carbonic acid added laſt, a white cloud is ſeen hovering over, and defining the point of contact of the two, and the abſorption is more gradual. The ſame condenſation may be ſhewn over water, (though not with the accuracy of meaſuring the reſpective quantities of the gaſes) ſimply by incloſing any veſſel full of a mixture of lime and muriat of ammonia in an atmoſphere of carbonic acid gas, the ammoniacal gas given off by this mixture ſeizing on the carbonic acid the inſtant it touches it.

The common ſolid carbonat of ammonia, when freſh made, or kept in a very cloſe-ſtopped bottle, is a hard, tough, ſtriated, white-ſemitranſparent maſs of no determinate form. Its ſmell is extremely pungent, and, to moſt perſons, agreeable, but when ſtrongly ſnuffed up it is apt to excoriate the noſtrils. Its taſte is ſalt, cool, and ſtimulating. It is very ſoluble in water, producing cold during the ſolution. At 55° water diſſolves half its weight, and at 120° degrees its own weight; but at this heat the alkali begins to volatilize pretty freely, ſo that the ſaline contents of the hot ſolution are always varying. The ſalt, whether wet or dry, is remarkable for its volatility, the more in proportion to the heat, but even at a low temperature it is always loſing weight whilſt it retains its ſcent.

The cryſtallization of carbonat of ammonia is very difficult on account of its volatile nature, ſo that the common way of making a hot ſaturated ſolution and cryſtallizing by cooling will ſeldom anſwer. Bergman obtained tolerably regular cryſtals by taking a ſaturate ſolution at a moderate temperature, ſaturating this with carbonic acid, and then expoſing it to ſevere cold, the cryſtals appeared to be octohedrons with truncated angles.

Carbonat of ammonia, on account of its rapid ſolubility, and the quantity of carbonic acid it contains, efferveſces more violently with acids than moſt of the other carbonats.

A remarkable change takes place in this ſalt if expoſed to the air. Let any quantity of the hardeſt and the moſt pungent carbonat of ammonia be bruiſed to powder, ſpread on a plate, and expoſed to the air, and in a very ſhort time the ſurface becomes crumbly, and of an opake white, and the whole atmoſphere around will be ſtrongly ſcented with a pungent ammoniacal vapour ariſing from the rapid volatilization of the ſalt. This loſs of weight is ſo great, that in the courſe of ten or twelve hours no more than from forty to ſixty per cent of the original weight will remain, and the ſalt is then changed to a ſoft pulverulent meal-like ſubſtance almoſt without ſcent or pungency to the taſte. This ſame change takes place ſooner or later to the freſh ſalt, if kept in bottles careleſsly ſtopped.

Hence it appears probable that the recent or pungent carbonat contains a quantity of ammonia in exceſs, to which it owes its pungency and volatility, and the ſcentleſs effloreſced ſalt probably conſiſts of carbonic acid and ammonia in mutual ſaturation, together with a quantity of water.

This ſalt is ſoluble in alcohol, and thus an ammoniacal ſpirit is made by diſtilling the two together, often with various aromatic additions. See AMMONIA.

CARBONAT of *Potaſh.—Common potaſh.—Pearl-aſh.—Salt of Tartar.—Vegetable fixed Alkali.* The vegetable fixed alkali was ſo named by the chemiſts of the laſt and former ages becauſe it was procured in large quantities from vegetable ſubſtances, and was in no caſe ſuppoſed to be of mineral origin. From certain late analyſes, however, by Klaproth and other able chemiſts, it has been diſcovered to enter as an eſſential ingredient into the compoſition of leucite, lepidolite, and a few other minerals, which are ſuſpected by none to be of vegetable origin. But though the exiſtence of potaſh in a mineral ſtate has been thus demonſtrated, yet it is ſo ſmall in quantity and ſo difficultly procurable, that all the vaſt ſupplies of this ſubſtance which civilized life requires have as yet been entirely obtained from the combuſtion of vegetables.

If the woody or annual ſtems of vegetables that have grown in ſoils unimpregnated with common ſalt, after being ſufficiently dried, are ſet fire to, the watery, the reſinous, the oily, the acid, and carbonaceous portions are volatilized and diſſipated in a ſtate of more or leſs compleat decompoſition, and there remains behind a reddiſh or whitiſh powder called *aſhes;* conſiſting chiefly of the earthy and metallic ingredients of the vegetable, together with a variable proportion of ſubcarbonat of potaſh. By lixiviation the alkaline part is diſſolved out, and this ſolution, when boiled down to dryneſs and melted, leaves behind a dark brown ſaline maſs, conſiſting of the carbonated potaſh, coloured by a ſmall portion of vegetable inflammable matter; and in this ſtate it is known in the Engliſh market by the name of *potaſh.* Calcination at a moderate red heat completely burns off the colouring particles, and the ſalt becomes of a ſpongy texture, and has a beautiful bluiſh white tinge, and is then called *pearlaſh.* Such is in general the proceſs by which the vegetable fixed alkali is ſeparated from the ſubſtances with which it is combined by nature and prepared for uſe. We ſhall now proceed to deſcribe more at large the different methods of extracting this ſalt.

The ſimpleſt and rudeſt preparation of potaſh is called *aſh-balls* in England, and *weed-aſh* in Ireland. It cannot be ſaid properly ſpeaking to be an article of commerce, although a conſiderable quantity is annually made by the peaſantry of both countries, and diſpoſed of among the neighbouring farmers and bleachers. The vegetable from which in England and Scotland this impure alkali is produced, is the common fern or brakes (*Pteris aquilina,* Linn.) Many rough and heathy diſtricts are entirely covered by this plant, which, when it has attained its full growth, about the middle of July, is cut down, and after being half-dried in the open air is gathered into ſmall heaps and kindled. The combuſtion proceeds ſlowly, being accompanied by a ſmothering ſmoke and little or no flame, till the whole is reduced to a reddiſh-grey aſh: this being carefully collected is ſprinkled with a little water, and then moulded by hand into balls three or four inches in diameter, which, when they have acquired a certain ſolidity by drying in the ſun, are ready for ſale. In Ireland, thiſtles, docks, and weeds of all kinds are mixed with the fern, and the aſhes are diſpoſed of in their looſe pulverulent ſtate without any further preparation. According to Dr. Home, fern-aſhes contain about $\frac{1}{9}$ of their weight of ſalt, conſiſting principally of ſulphat and ſubcarbonat of potaſh: 1000 parts of the plant cut in Auguſt and thoroughly dried afford 36.46 of aſhes, from which are obtained by lixiviation 4.5 of ſalt. The common Iriſh weed-aſhes have been analyſed by Mr. Kirwan, and when deprived of their water by a red heat, appear to contain one part of ſalt for 3.5 of aſh; of this the free alkaline portion, however, amounted only to $\frac{1}{21}$ of the whole.

The potaſh of commerce, or *black potaſh*, as it is alſo called, is univerſally procured from the combuſtion of wood; and therefore its preparation can only be undertaken with ſucceſs in thoſe uncleared countries where are vaſt natural foreſts, and where, from the badneſs of the roads, and imperfection of water communication, the value of timber is no more than that of the labour required to fell it. The only diſtricts of Europe in which any conſiderable quantity of potaſh is made, are the mountainous foreſts of Germany, and the extenſive woodland tracts of Poland and Ruſſia. The Britiſh market, however, is principally ſupplied from the United States of North America, a country in which, from its rapid increaſe of population, there is a conſtant demand for cleared land for the purpoſes of agriculture, and therefore, where timber is looked upon rather as an incumbrance than as contributing either to the beauty or value of the ground on which it ſtands.

The American method is to pile up the wood, as ſoon as it is ſufficiently dry to burn, in large heaps, and reduce it as quickly as poſſible to aſhes: theſe aſhes are then put into a wooden ciſtern with a plug at the bottom of one of the ſides, and a quantity of water ſufficient to make a ſtrong lixivium is added; after ſtanding for an hour or two the plug is withdrawn, and the water holding the potaſh in ſolution, runs out, leaving the earthy part ſtill impregnated with alkali in the ciſtern. This ſolution is then evaporated to dryneſs in iron pans and haſtily fuſed into compact reddiſh brown maſſes of ſemi-cauſtic potaſh, in which ſtate it is fit for the market.

In Germany, where the value of wood is greater, and where more intelligence and economy are practiſed in the preparation of potaſh, the general method of proceeding is the ſame as that juſt mentioned, but with ſuch variations, as though ſeemingly of little conſequence, materially augment the produce of alkali. Care is taken to ſelect ſuch kinds of wood as are the richeſt in potaſh, the combuſtion is ſlower, and of courſe the temperature lower, in conſequence of which, but little is loſt by volatilization; the lixiviations alſo of the aſhes are judiciouſly repeated till the whole of the alkali is extracted.

The common Ruſſian potaſh is the impureſt of all, containing nearly one half its weight of earth; and is thus prepared. A large pit is dug, into which are thrown burning brands and the ſmaller extremities of the branches, and when the whole is well kindled, the pit is filled up with logs and other large pieces, which at length, though very ſlowly, are reduced to aſhes. The coarſer part of the aſhes is then ſeparated, by ſifting, from the finer; all the alkali that it contains is procured by lixiviation, and this liquor is mixed with the remainder of the aſhes and wrought into a paſte. A pile is then built of wood, the interſtices of which are filled with this paſte, which being ſet fire to, the whole is reduced to aſhes. This proceſs is repeated ſeveral times till the aſhes begin to clot and become hard; the moſt compact pieces, being then ſelected, are packed up for ſale without any further preparation: the reſt are lixiviated and boiled down to dryneſs in the uſual manner.

Potaſh is converted into a much purer alkaline ſalt, called *pearlaſh*, by calcination: for this purpoſe the potaſh broken into moderately ſmall pieces is ſpread on the floor of a reverberatory furnace, and being then kept red hot, but not melted, for an hour or two, ſtirring it occaſionally with an iron rake, all the carbonaceous and colouring particles are burnt out, and there remains behind a dry, porous, and conſiderably cauſtic ſalt, extremely deliqueſcent, and from its bluiſh white colour, called pearlaſh.

It has been thought of conſequence, in an economical point of view to diſcover the proportion of potaſh afforded by different vegetables, and many analyſes have been made for this purpoſe. They are, however, for the moſt part unſatiſfactory, as they indicate only the proportion of ſoluble ſaline ingredients without diſtinguiſhing the carbonated potaſh from the ſulphat and muriat of potaſh with which it is always mixed. The moſt remarkable and intereſting reſults will be found in the following table; part of which were aſcertained by a committee of the academy of ſciences at Paris and the reſt by the chemiſts whoſe names are ſubjoined: 100 parts of each different ſpecies being previouſly thoroughly dried were burned by an open fire to aſhes, which after being weighed, were accurately lixiviated till all their ſaline contents were extracted.

| 100 Parts. | Aſhes. | Salt. | Salt from 100 parts of aſhes. | Authority. |

Upon a curſory inſpection of this table it appears that the ſucculent herbaceous plants afford a prodigiouſly greater proportion both of aſhes and ſalt than the ſhrubby and ligneous ones: it is, however, to be obſerved, that they were all reduced to a ſtate of perfect dryneſs before being weighed, a circumſtance which will in a conſiderable degree account for the apparently greater quantity of ſalt contained in the ſucculent vegetables; for while the different kinds of wood will not loſe more than $\frac{1}{3}$ or even $\frac{1}{5}$ of their weight in drying, fumitory will probably loſe $\frac{9}{10}$ or even more. It is not likely, therefore, that it can ever be worth while to be at the expence of cultivating fumitory and wormwood, as ſome ſpeculators have propoſed, for the ſake of the alkali contained in their aſhes.

The varieties of pot and pearlaſh, which are found in the markets, would no doubt on analyſis afford very different reſults, eſpecially with regard to the proportions of earthy matter, of water, and of carbonic acid; it is not therefore perhaps much to be regretted that we poſſeſs no very accurate analyſis of any of them. The only one on which any reliance can be placed, is of Dantzic pearlaſh by Mr. Kirwan, in which are contained about

| | |
|---|---|
| 60.3 | potaſh |
| 22.4 | carbonic acid |
| 7.2 | water |
| 8.7 | ſulphated potaſh |
| 0.7 | muriated ditto |
| 0.7 | earth |
| 100.0 | |

But if the analyſis of any particular ſample is of little conſequence, generally ſpeaking, yet it is of conſiderable importance both to the manufacturer and chemiſt to be in poſſeſſion of a compendious and accurate mode of aſcertaining the contents of the various kinds of pot and pearlaſh, in order to make advantageous purchaſes of articles, in the intrinſic worth of which there is ſo much difference. Upon the whole perhaps the beſt mode of proceeding on ſuch occaſions is as follows.

1ſt. Prepare a diluted ſulphuric acid, by mixing the concentrated acid, called oil of vitriol, with three times its bulk of diſtilled water. Then teſt it by taking 100 grains of the diluted acid, and adding muriat of barytes as long as any precipitate falls down. The ſulphat of barytes thus prepared, when waſhed with cold water and dried at a low red heat, contains 33.3 per cent. of ſulphuric acid; hence the real acid in any quantity of the diluted acid is readily aſcertained.

2d. Pulverize 500 grains of the alkali under examination, and digeſt it in warm diſtilled or rain-water, adding freſh portions of this fluid as long as any thing is diſſolved. Then put all the ſolutions together, and drop in the teſted ſulphuric acid from a vial containing a known weight of the ſame, till the ſlighteſt poſſible exceſs of acid is indicated by a paper tinged with litmus. After this, heat the liquor to expel all the carbonic acid, and if the liquor changes the colour of turmeric paper, add a few more drops of ſulphuric acid, till it ceaſes to ſhow an exceſs of alkali. Now weigh the vial of ſulphuric acid, and thus aſcertain how much has been expended in ſaturating the alkali, and for every 100 parts of real acid (as previouſly determined by muriat of barytes) thus employed, ſet down 121.2 of pure potaſh. The alkali being the part which gives value to the whole, this is all the examination which in ordinary caſes is required; but if the analyſis is to be carried further,

3d. Take 500 grains more of the alkali, diſſolve it in boiling water, and pour the filtered ſolution into a flaſk; then place the flaſk and a vial containing about three ounces of pure and moderately ſtrong nitric acid into the ſame ſcale of an accurate balance, and equipoiſe them. Afterwards add the acid, drop by drop, to the alkali as long as any efferveſcence takes place, and the loſs of weight indicates the amount of carbonic acid. The ſolution will now probably cryſtallize; a ſufficient quantity of diſtilled water is therefore to be added in order to diſſolve the cryſtals, and nitrat of barytes is to be dropped in as long as any precipitate takes place: 100 parts of the dried ſulphat of barytes, thus procured, indicate 73.6 of ſulphated potaſh. This being removed, add muriat of ſilver to the clear liquor till it ceaſes to be decompoſed: 100 parts of muriated ſilver ſhew 41.34 of muriated potaſh. Thus the ſaline contents are all aſcertained; viz. potaſh, carbonic acid, ſulphat, and muriat of potaſh. The earthy part is ſhown by the inſoluble reſidue.

Having now treated of the impure ſubcarbonats of potaſh, we ſhall conclude this article by an account of the purer ſubcarbonats, and the perfect carbonat of potaſh.

The moſt important of the purer ſubcarbonats is *ſalt of tartar;* which is prepared in the wine countries in large quantities, and is the kind generally uſed in medicine. The lees of wine and the tartar that is depoſited on the ſides of the caſks, are put into ſmall bags about a foot long, and ſubjected to a ſtrong preſſure, in order to ſqueeze out all the wine, which is diſpoſed of to the brandy diſtillers; the contents of the bags being carefully taken out without breaking form maſſes like loaves, which are dried in the ſun, and then piled up in a furnace with alternate ſtrata of charcoal. The fire being kindled and the draft properly regulated, the acid and inflammable matter of the tartar are burnt off without fuſing the alkaline part; when the proceſs therefore is finiſhed, theſe loaves remain of nearly the ſame ſize as before, but very porous and perfectly white. Being then broken into pieces they are diſſolved in hot water, and the clear lixivium being evaporated to dryneſs and calcined to whiteneſs, is ready for ſale; 2½ parts of tartar yield one of ſalt of tartar.

A more expeditious but leſs economical way of procuring ſalt of tartar, is to mix equal parts of crude tartar and nitre, and project the mixture into a red-hot crucible. A rapid deflagration takes place: the nitric acid and the combuſtible parts of the tartar mutually decompoſe each other, and there remains behind the alkaline baſe of each united with ſome carbonic acid. This preparation is called *white flux, nitre fixed by tartar*, *extemporaneous potaſh.*

The perfectly ſaturated carbonat of potaſh has not been known to chemiſts longer than from the time of Bergman. It may be prepared in two ways; the firſt, which was diſcovered by Berthollet, is as follows. Take equal parts of ſalt of tartar and carbonat of ammonia, diſſolve the whole in warm water, pour it into a retort, and proceed to ſlow diſtillation; the potaſh having a ſtronger affinity for carbonic acid than ammonia has, deprives this latter of its acid, and in conſequence ammoniacal vapour is given out in great quantity: when this ceaſes, the contents of the retort are to be poured into a convenient veſſel, where by refrigeration a copious depoſition of cryſtallized carbonat of potaſh will take place.

The other method, and that which is generally practiſed, is to put a ſolution of ſalt of tartar into an apparatus for impregnating water with carbonic acid, and then to throw in this acid till the alkali is quite ſaturated and refuſes to take up any more.

The form of the cryſtals of carbonat of potaſh is that of a tetrahedral rhomboid with dihedral ſummits. This ſalt requires for its ſolution about four parts by weight of cold water, but no more than $\frac{5}{6}$ of its weight of boiling water: a conſiderable degree of cold is produced during its ſolution. It is hardly at all ſoluble in cold alcohol, and requires above 200 parts of this fluid when boiling for its compleat ſolution.

It has been analyſed by both Bergman and Pelletier; each of theſe chemiſts agree in the proportion of alkali, but they differ materially in their eſtimation of the water and carbonic acid.

| Bergman. | Pelletier. | |
|---|---|---|
| 48 | 48 | potaſh |
| 20 | 43 | carbonic acid |
| 32 | 9 | water |
| 100 | 100 | |

The taſte of this ſalt is cool and freſh, with hardly any of the alkaline flavour; on which account, and becauſe it is fully ſaturated with carbonic acid, it is greatly preferable to ſalt of tartar in the compoſition of effervesſcing drafts, and for other medical purpoſes. It is neither efflorefcent nor deliqueſcent in the air. It is decompoſable with abſtraction of the acid by barytes, lime, and ſtrontian, and with abſtraction of the alkali by all the mineral, and by moſt of the vegetable acids.

The uſes of potaſh are innumerable. It is conſumed in the greateſt quantities by ſoap-boilers, bleachers, and glaſs-makers. In the laboratory it is in conſtant and indiſpenſable ſervice.

CARBONAT *of Soda. Kelp. Barilla. Natron.* This ſalt is found to exiſt both in the vegetable and mineral kingdoms of nature. When mineral, it is met with either diſſolved in the water of certain hot ſprings, as thoſe of Carlſbad in Bohemia; or of certain lakes, as the natron-lakes of Egypt and Hungary; or it occurs in the ſtate of a foſſil-ſalt, as in the foſſil natron of Tripoli, called trona. In the vegetable kingdom carbonat of ſoda has been found to exiſt, ready formed, in the Salſola ſoda, and in all probability is contained in all thoſe ſucculent ſaline plants that grow in places impregnated with muriat of ſoda. In order to ſupply the vaſt demands for this alkaline ſalt, it is procured from both the ſources above mentioned, by proceſſes which we ſhall now relate, beginning with the mineral ſoda.

There are two varieties of mineral ſoda, the ſtriated and compact. The ſtriated has been hitherto procured only from Africa. It is found between Tripoli and Fezzan, forming a very thin ſtratum juſt below the ſurface of the ſoil. It is of a ſtriated cryſtalline texture, ſomewhat reſembling fibrous gypſum. It is collected to the annual amount of ſome hundred tons, but ſcarcely ever finds its way to the European markets. It is diſtinguiſhed from common carbonat of ſoda, by being fully ſaturated with carbonic acid, by containing only a ſmall quantity of water of cryſtallization, and by not effloreſcing on expoſure to the air. Its component parts, according to Klaproth, are

| | |
|---|---|
| 37. | ſoda |
| 38. | carbonic acid |
| 22.5 | water |
| 2.5 | ſulphated ſoda |
| 100.0 | |

The compact mineral ſoda is procured in quantity only from Egypt and Hungary. The Egyptian natron lakes, ſix in number, are ſituated in a barren valley, about 30 miles weſtward of the Delta. During three months in the year they are ſupplied with water from copious ſprings, but as they receive no water during the reſt of the year, ſome of the ſmaller and ſhalloweſt ones are generally dried up during the ſummer. The ſoil conſiſts of lime-ſtone mixed with gypſum, and for the moſt part covered over with ſand. The ſalts contained in theſe lakes are muriat and carbonat of ſoda, of which the former is depoſited for the moſt part on the deepeſt ſide, while the latter is formed among the ruſhes that grow in the ſhallower places. The natron appears to be produced by the ſlow mutual decompoſition of the lime-ſtone and common ſalt, aſſiſted by the ruſhes up the ſtems of which the natron riſes by the force of effloreſcence. When the ruſhes thus encruſted are broken by the wind, the ſoda on their ſurface aſſumes its proper quantity of water, and forms a confuſedly cryſtallized ſtratum of the thickneſs of from one to twelve inches according as the weather and other circumſtances are more or leſs favourable. The effloreſcences on the ſhore of the lakes and the detached cryſtals that form at the water's edge are mixed with a much ſmaller quantity of ſalt than the larger maſſes; theſe latter however being more convenient to carry, and being procured with the leaſt trouble, are conſtantly preferred, and as no ſubſequent purification is had recourſe to, the natron of Egypt is by no means ſo valuable as it might eaſily be made. It is chiefly exported to Greece and other parts of Turkey, alſo to Venice, France, and Britain.

The chief natron lakes of Hungary are four in number, ſituated between Dobritzin and Groſwaradin. Theſe, in the winter ſeaſon, when full of water, are from one to two miles in circumference, but by the middle of April or the beginning of May they are generally dried up, except ſome pits that have been ſunk by art below the general level. In a few days after the water has diſappeared, the whole ſurface of the cavity becomes white with ſaline effloreſcences of natron mixed with ſulphat of ſoda; theſe being removed, a freſh incruſtation is formed in three or four days, and continues to be renewed with equal rapidity during the whole dry ſeaſon of the year. A very heavy ſhower is ſufficient to fill the lakes, but in a day or two they are dry again, ſo that no very material interruption is experienced till the latter end of October: by this time the water in the pits is fully ſaturated with natron, a conſiderable proportion of which cryſtallizes during the firſt froſts of winter, and thus terminates the harveſt for the year; for after this the rains ſet in, and the lakes continue full of water till the enſuing ſpring. The Hungarian as well as the Egyptian natron ſeems to be brought into commerce without undergoing any preparation, as it appears in pulverulent maſſes of a dirty grey colour. The Hungarian natron has been analyſed by Lampadius, and the Egyptian by Klaproth, with the following reſults:

| Egyptian. | Hungarian. | |
|---|---|---|
| 32.6 | 14.2 | carbonat of ſoda. |
| 20.8 | 9.2 | ſulphat of ſoda |
| 15. | 22.4 | muriat of ſoda |
| 31.6 | 45. | water |
| | 9.2 | earth |
| 100.0 | 100.0 | |

By far the greater part, however, of the ſoda that is employed, is of vegetable origin, and, like pot-aſh, is procured from the combuſtion of plants. While the vegetables that grow in common ſoil yield pot-aſh, thoſe which flouriſh in ſalt water, or on the ſea-ſhore, or wherever the ſoil is ſtrongly impregnated with ſalt, yield ſoda. Of vegetable ſoda there are two varieties, viz. *barilla* and *kelp*, the former being made from the plants of the genera Salſola, Salicornia, &c. that grow on the ſea-ſhore; the latter being the produce of fuci, and other marine plants.

The beſt barilla (properly bariglia) is made from the ſalſola ſoda, which is an object of ſedulous and extenſive cultivation to the Spaniards on the ſhore of the Mediterranean, eſpecially in the vicinity of Alicant. It is ſown in light low ſoils, that are embanked on the ſide next the ſea, and furniſhed with flood-gates, by which the ſalt water may be occaſionally admitted. In autumn, when the ſeeds are ripe, the crop is cut down and dried; the ſeeds are rubbed out, and the reſt of the plant is burnt in very ſimple furnaces, the temperature of which is juſt high enough to cauſe the aſhes to enter into a ſtate of ſemi-fuſion, and concrete into compact cellular maſſes. The moſt eſteemed variety of this ſalt is called *ſweet barilla;* it is of a greyiſh-blue colour, and is covered over with a ſaline efflореſcence, when expoſed for a time to the air; it is exceedingly hard, and when applied to the tongue diſcovers a ſharp, pungent, alkaline flavour.

*Kelp* is made of what is vulgarly called ſea-weed, or ſea-wrack (whence the French term *ſoude de vareck*), that is, of ſuch of the leafy fuci, principally the *Serratus* and *Veſiculoſus*, as grow on rocks in the ſea, between the high and low water mark. The moſt favourable ſituation for theſe plants is a ſheltered bay, full of calcareous rocks. The ſeaſon for gathering the plants is from May to Auguſt. On the Britiſh coaſts they are cut with a ſcythe, as cloſe to the rock as poſſible, and then bound up into large bundles, which being faſtened to one end of a long rope, the other extremity of it is tied to a boat, and thus the labour of two or three men is capable of towing ſeveral tons weight to the ſhore. Theſe bundles, when landed, are to be opened, and their contents ſpread thinly on the ſhore to dry, turning them from time to time, leſt they ſhould ferment, by which both the quantity and quality of the kelp would be greatly deteriorated. The ware, when dry, ſhould be ſtacked ſecure from rain for a few weeks, till it becomes covered with a white ſaline efflореſcence, and then it is ready to be burnt. The furnace employed for this purpoſe uſed to be, and in many parts ſtill is, nothing but a round pit, three or four feet deep, and ſeven or eight feet acroſs, lined with ſtones; the more ſkilful kelp-burners, however, make uſe of a kiln of the following conſtruction.

It is built of ſtone, in the ſhape of a long open coffer, being 28 inches wide in the clear, about 2½ feet high, and from 8 to 18 feet long. The bottom of the kiln being covered with bruſhwood or heath, a thin ſtratum of the dried ware is ſhaken lightly upon it, and fire is applied to the leeward ſide of the kiln. It muſt now be ſupplied with freſh ware, thrown lightly on, whenever the combuſtion reaches the ſurface: if the weather is perfectly calm, no other precautions are required, than to take care that the fire is not ſtifled, but if it blows ever ſo little, the windward ſide of the kiln muſt be covered with ſods, and even both ſides, if the weather is at all boiſterous. When all the ware has been thrown on that is intended to be uſed at one time, care muſt be taken to cover every ſpot where the fire reaches the ſurface, with a little of the charred or leaſt burnt part. After a time, that part of the maſs which is neareſt to the ſides is ſeen to ſoften or melt, and now begins the moſt critical period of the whole proceſs. An iron bar, previouſly heated, is to be introduced among the ſoft matter, which by this means is to be ſlowly ſtirred up and incorporated, adding by degrees ſome of the leſs burnt portions, and in this manner the whole is to be kneaded together till it becomes a paſty ſemi-fluid maſs. It is a matter of conſiderable dexterity ſo to perform this proceſs as to be able to mix the duſt and fragments of a preceding burning, without too much cooling the whole. If when this incorporation of the materials is begun the maſs is too hard and dry, by waiting a ſhort time, it will be found to have acquired the neceſſary temper, but if it is dry and pulverulent like aſhes, it is expedient to have recourſe to a little common ſalt, which, acting as a flux, will begin the fuſion; or if the heat is very languid, a little pulverized brimſtone may be made uſe of. When the kelp has been thus prepared, and is grown cold, it is broken into large lumps and is fit for ſale. Well made kelp is of a bluiſh-grey colour, ſometimes approaching to green; it has more or leſs of a cellular texture, and contains pieces of charcoal inveloped in the maſs; when breathed on, it emits a faint ſulphureous odour; to the taſte it is cauſtic and alkaline, mixed with the ſavour of common ſalt. It yields eaſily to the knife, but poſſeſſes a conſiderable degree of toughneſs. If dry, it is uſually covered with a white ſaline efflореſcence. The proportion of pure ſoda which it contains varies, according to Kirwan and Jameſon, from 1.25 to 5. per cent.

Pure carbonated ſoda, from whatever ſubſtance, and by whatever means it is procured, is eſſentially the ſame. Its uſual ſtate is that of clear colourleſs cryſtals, in the form of rhomboidal octohedrons, or oblique tetrahedral priſms. To the taſte it is ſweetiſh, cooling, and ſub-alkaline. It is ſoluble in 2½ times its weight of water at 50°, and at a boiling heat diſſolves in its own water of cryſtallization. By expoſure to the air, it effloreſces, and is converted to a white mealy powder, with the loſs of the greateſt part of its water, and this powder, when kept for ſome time at a low red heat, concretes into lumps, loſes a ſmall portion of its carbonic acid, and all its water, and is then called deſiccated ſoda. The component parts of cryſtallized carbonat of ſoda have been variouſly eſtimated, though the difference has not been very great. We ſhall mention the proportions as given by Bergman, and thoſe adhered to by Mr. Kirwan.

| Berg. | Kirw. | |
|---|---|---|
| 22. | 21.58 | ſoda |
| 16. | 14.42 | carbonic acid |
| 62. | 64. | water |
| 100. | 100.00 | |

Soda, however, is capable of combining with a larger proportion of carbonic acid by diſſolving the cryſtallized carbonat in water, and then throwing in carbonic acid gas. The cryſtals that are now depoſited will be found to contain a conſiderably leſs quantity of water, and their ſweetiſh ſub-alkaline flavour will be changed for a cooling ſaline one; ſo that in this ſtate it reſembles the trona. It has not, however, been analyſed with ſuch accuracy as to enable us to ſtate the proportions of its ingredients.

Carbonated ſoda is decompoſed with abſtraction of its baſe by almoſt all the other acids, and with abſtraction of its acid by barytes, lime, ſtrontian, and potaſh.

The purpoſes to which carbonated ſoda is applied are in general the ſame as thoſe for which carbonat of potaſh is uſed; the circumſtances that induce the occaſional preference of one to the other will be mentioned in their proper places.

CARBONAT *of Barytes.* This compound is both found native, and may be procured artificially. For the mineralogical deſcription of the native barytes, ſee WITHERITE; and for the way of procuring the artificial carbonat, ſee BARYTES.

The artificial carbonat appears, from the analyſes of Klaproth and Pelletier, to be compoſed (when dried and ignited for a few minutes at a low red heat) of 22 parts of carbonic acid and 78 of barytes.

The artificial is much more ſoluble than the natural carbonat in all the acids. The muriatic or nitric acids, moderately diluted, diſſolve it with great eaſe and with much efferveſcence. This carbonat is ſcarcely ſoluble in water, but when in fine powder diffuſed through water, and a ſtream of carbonic acid is ſent through it, water then diſſolves (according to Fourcroy) about $\frac{1}{830}$ of its weight; but the carbonat is not cryſtallizable from the ſolution, the exceſs of carbonic acid flying off by expoſure to air or heat, and the carbonat then returning to its pulverulent ſtate.

Carbonat *of Strontian.* This carbonat is found native (ſee Strontianite), and may alſo be readily made by artificial means (ſee Strontian).

Carbonat of ſtrontian, gently dried and ignited, is compoſed, according to Klaproth, of about 30 of carbonic acid, and 70 of ſtrontian. Nearly the ſame obſervations belong to this carbonat as to the carbonat of barytes, but the affinity of the carbonic acid is not ſo ſtrong, and it diſſolves in acids ſomewhat more readily.

Carbonat *of Lime.* Under the article Limestone will be deſcribed moſt of the natural varieties of this very important claſs of minerals; and under Lime the method of freeing them from their carbonic acid, and of analyſis in general.

The pureſt carbonat of lime is prepared by adding carbonated ammonia to a pure nitric or muriatic, or any other ſolution of lime. The precipitation is much aſſiſted by a boiling heat, for this alkali contains ſo much carbonic acid that a part of the lime would be re-diſſolved in this acid unleſs the exceſs be driven off by heat. The white precipitate waſhed thoroughly, and heated in a low red heat for about ten minutes, is then very pure carbonat of lime, containing ſcarcely any water, and no remaining alkali, and conſiſts ſimply of about 45 parts of carbonic acid to 55 of lime.

The carbonats of potaſh or ſoda will alſo have the ſame effect as the carbonat of ammonia, but it is much more difficult to ſeparate entirely every atom of the alkali from the precipitate when the fixed alkalies are uſed than with the volatile, as in the latter caſe the laſt adhering portion is diſſipated by the heat. In conſequence, the carbonat of lime prepared by the ammoniacal carbonat has a dry, looſe, incoherent feel, like powdered ſtarch, which the other has not.

Carbonat of lime is not in any ſenſible degree ſoluble in pure water, but with an exceſs of carbonic acid it diſſolves without difficulty, and hence the lime of lime-water will be precipitated as a carbonat by a ſmall quantity of water holding carbonic acid, and will be re-diſſolved by a larger portion of the ſame, as explained under the article Carbonic *acid.*

The ſolutions of carbonat of lime in water, with exceſs of carbonic acid, change the red colour of Braſil wood to blue, as obſerved by Bergman. But they alſo change litmus-blue to red, on account of the exceſs of carbonic acid.

From the experiments of many accurate analyſts, compared by Kirwan, it appears, that carbonated lime with its own weight of carbonic acid is rendered thereby ſoluble in water, however ſmall the quantity of fluid, but in proportion to the quantity of water leſs carbonic acid will ſuffice.

Carbonat *of Magneſia.* This carbonat is not found native, except largely mixed with ſome kinds of limeſtone, or in ſolution in ſome mineral waters.

The artificial carbonat (the common *magneſia alba* of the ſhops) is prepared by decompoſing ſulphat of magneſia, or Epſom ſalt, by carbonat of potaſh. The following is the common proceſs. Diſſolve a pound of ſulphat of magneſia in five pints of water, add to this a pound of good carbonat of potaſh, diſſolved in a like quantity of water, and boil them for a few minutes. A copious white precipitate is produced immediately, which renders the whole mixture very thick. Strain it, while hot, through linen, and waſh the white maſs left on the ſtrainer repeatedly with boiling water poured on it, till the clear filtered water drops through quite taſteleſs. Then dry the precipitate over a fire, and a white taſteleſs powder is left, which is the common magneſia. The drying of this precipitate is extremely tedious, for being of a very light ſpongy nature, it holds a large quantity of water without dripping, and conſequently the filter ſoon becomes uſeleſs. In the large way the wet maſs is firſt laid on large ſlabs of chalk, which ſuck up much of the moiſture very expeditiouſly.

Common carbonat of magneſia, in its pulverulent ſtate, is exceſſively light, and lies ſo looſe that a ſmaller weight of it will fill a bottle of a given ſize than almoſt any other known powder. It conſiſts of water, carbonic acid, and magneſia, in proportions ſomewhat varying. The quantities of each have been thus eſtimated: by calcination in a full red heat for about half an hour, both the water and the carbonic acid are expelled, and the loſs amounts on an average to about 55 per cent. On the other hand, 100 parts of the ſame carbonat loſe by ſolution in acids only 34 parts, which are carbonic acid, and hence the conſtituents of 100 parts of the carbonat will be 34 of carbonic acid, 21 of water, and 45 of magneſia. The calcination of this carbonat is eaſy, compared to that of lime, and in the proceſs it ſhrinks to a very ſmall bulk, and becomes ſomewhat harſh to the feel. When quite freed from water and carbonic acid, the pure magneſia that remains is the Magnesia *uſta* of the ſhops, which ſee.

The quantity of alkali directed for the decompoſition of the ſulphat of magneſia is ſomewhat more than neceſſary for the purpoſe, ſo that the clear liquor that firſt comes off through the filter is a ſolution of ſulphat of potaſh with carbonat of potaſh.

Another form or ſpecies of carbonat of magneſia is that in which the earth is fully ſaturated with carbonic acid, forming a cryſtallizable ſalt. It is very ſoluble in water, whereas the common pulverulent carbonat of magneſia is abſolutely inſoluble in pure water.

The cryſtallized ſpecies is formed in two ways. It is produced by mixing the ſame materials as the common carbonat, but *without applying heat.* The exceſs of carbonic acid, which the heat drives off, remains in this caſe united with a portion of the magneſia, and if this mixture be left to ſpontaneous evaporation, a quantity of ſmall long four-ſided priſmatic cryſtals may be picked out of the cryſtals of ſulphat of potaſh, which are the cryſtallized carbonat of magneſia. But a neater and better way of preparing them is to paſs a ſtream of carbonic acid through water rendered milky by the common magneſia, which will be ſeen gradually to become clear, owing to the ſolution of the earth in the carbonic acid and water, after which let the ſolution evaporate ſlowly in a warm room. The cryſtals will then form readily, or even if the ſolution is pretty ſtrong, they will depoſit by mere reſt for a time.

This ſalt conſiſts, according to Bergman, of about 25 of magneſia, 50 of carbonic acid, and 25 of water, when analyſed as the former carbonat. It is ſoluble in 48 parts of cold water, but in much leſs when the water alſo has an exceſs of carbonic acid, and hence it is often found during the ſlow evaporation of many of the carbonated mineral waters.

Carbonated magneſia, in any ſtate, is decompoſed by potaſh, ſoda, barytes, lime, and ſtrontian, and alſo by all the ſalts, with the baſis of theſe three earths. Ammonia and magneſia ſeem to have nearly equal affinities for carbonic acid, ſo that either of the two will only partially decompoſe the ſaturated carbonat of the other ſubſtance. Thus, if pure ammonia be added to the cryſtallized magneſian carbonat, the precipitate is not pure magneſia, but the *ſub-carbonat*, or common magneſia; and on the other hand, the ſame ſub-carbonat is produced, if pure magneſia be added to carbonat of ammonia. In either caſe alſo a part of the ammonia unites with the magneſia and carbonic acid, (as Fourcroy has obſerved) forming a triple ſalt, the *ammoniaco-magneſian carbonat*.

Carbonat *of Alumine, Glycine, Zircon*, &c. For the remaining earthy carbonats, ſee the reſpective earths.

Carbonats (*Metallic*). See the reſpective metals.

Carbonat *of Lime*, in *Agriculture*, a term applied to lime in a ſtate of combination with carbonic acid. This ſort of union is frequently met with in nature, and extends to all the ſtony ſubſtances which are diſtinguiſhed under the title *calcareous*, ſuch as lime-ſtone, chalk, marble, &c. In burning or converting theſe ſubſtances into lime, they are deprived of their carbonic acid or fixed air; but on cooling begin to abſorb it again from the ſurrounding atmoſphere. See Lime.

Lime, when in the ſtate of a carbonat, is frequently termed *effete lime*, and may often be employed for the purpoſes of agriculture with much greater benefit than in its cauſtic ſtate, or that of quick-lime.

CARBON-BLANC, in *Geography*, a town of France, in the department of Gironde, and chief place of a canton, in the diſtrict of Bourdeaux. The place contains 1800, and the canton 16,933 inhabitants: the territory comprehends 24½ kiliometres, and 20 communes.

CARBONE, a ſmall river of Spain, which runs into the Guadalquiver, a little above Seville.

CARBONELLI, Steffano, in *Biography*, an Italian performer on the violin, brought into England by the duke of Rutland, about the year 1720. He had been a ſcholar of Corelli, and was ſaid to play much in his manner. His hand was not brilliant, but he had a good tone, and knew muſic well; as a book of 12 ſolos, which he dedicated to his patron, the duke of Rutland, teſtified; the ſix firſt had a double-ſtopped fugue in each, and the reſt had pleaſing melodies in correct and judicious counterpoint; nor were they deſtitute of invention, as far as his ideas and hand could carry him. We have ſeen the book, which would be now difficult to find. It is a folio, engraved on copper.

In 1722, he had a benefit concert at Drury-lane theatre, of which the bill of fare is minutely given in the Daily Courant; (ſee Hiſt. Muſ. iv. 648.) by which we may judge of the muſical dainties of the ſeaſon.

Carbonelli was a ſteady and judicious leader, and, on his arrival in England, was placed at the head of the Opera orcheſtra, where he continued to lead, till 1725, when he reſigned, and was engaged by Mr. Fleetwood at Drury-lane, and there played concertos in the ſecond muſics, and frequently ſolos between the acts. But he reſigned this ſtation when Handel began to perform oratorios, in which he continued to lead as long as their great author ſurvived. Late in life, relinquiſhing muſic as a profeſſion, he entered into the wine trade, and eſtabliſhed a houſe, which ſtill ſubſiſts. He was a man of worth and probity, and honoured with general eſteem for his private virtues as well as his profeſſional talents. While he led the band at Drury-lane, ſir Richard Steel, in his comedy of The Conſcious Lovers, introduced him to play a ſolo for the amuſement of Indiana, taking occaſion in the dialogue, after his departure, to make Bevil jun. pay him and men of talents many compliments. He died in 1772.

CARBONI, in *Geography*, a town of Naples, in the province of Baſilicata; 16 miles S.W. of Turſi.

CARBONIC ACID, Carbonic Acid Gas, or *Fixed Acid.*—Aerial acid.—Mephitic acid.—Kohlenſaure, Germ. —Acide carbonique, Fr. in *Chemiſtry*.

Carbonic acid, in its uncombined ſtate, is only known to us as a gas, and it is the firſt gas in which acid properties were clearly diſcovered. It is known to be ſo by reddening certain vegetable blues, by neutralizing alkalies and alkaline earths, and by being formed by the union of a combuſtible baſe.

The ſources of this acid are immenſe, and widely diffuſed. The chief are the following.

1. The atmoſphere always contains a ſmall portion, which varies in the immediate vicinity of places where the proceſſes of reſpiration and combuſtion are going on, though ſomewhat leſs than might be expected. The general average is eſtimated at about one hundredth part. It is readily extracted from a confined portion of the atmoſphere by the contact of lime or the cauſtic alkalies.

2. Almoſt every natural ſpring, as it riſes from the earth, contains a portion of this air; and ſome waters hold ſo large a portion as to give them, when expoſed to the air, a very briſk, frothy appearance, and a very ſenſible taſte and decidedly acid properties. The celebrated ſprings of Spa, Pyrmont, and Seltzer, are of this kind, and the moſt highly carbonated water of them contains about its own bulk of the gas.

3. Every proceſs in which coal, wood, or any other carbonaceous ſubſtance is burnt, is one which generates this acid gas. The ſame may be ſaid of the proceſs of reſpiration.

4. The vegetation of plants under ſome circumſtances generates carbonic acid.

5. The ſpontaneous decompoſition of vegetable and animal matter produces this gas in abundance; hence fermentation and putrefaction are carbonating proceſſes.

6. But the largeſt ſtore of carbonic acid that exiſts is that enormous quantity which is ſolidified in all the immenſe beds of lime-ſtone, chalk, and calcareous ſtones with which every part of the globe abounds. Many of theſe contain 40 per cent. or even more of their *weight* of this acid.

Carbonic acid gas, or fixed air, has the following properties. It is permanently gaſeous at any temperature or preſſure. It is fatal to animal life, any living creature immerſed in it periſhing as ſoon as it would by total interruption of reſpiration. Hence the ſmall, warm-blooded animals die in it almoſt immediately; dogs, and animals of bulk, ſpeedily become ſenſeleſs in it, but recover, if removed in a ſhort time; frogs, and cold-blooded animals, live in it for a conſiderable time, owing to their power of ſubſiſting for a time without external reſpiration; but when this is paſt they periſh as the warm-blooded animals. This air is equally incapable of maintaining combuſtion, ſo that a candle let down into a jar of it is extinguiſhed as ſoon as it enters the gas as effectually as if dipped into water. Even the admixture of ſo ſmall a proportion as one-ninth of carbonic acid gas renders common air unable to maintain combuſtion, according to Mr. Cavendiſh's experiments. It is the heavieſt of all the known gaſſes, except the ſulphureous. Hence, as ſoon as generated, it falls through the atmoſphere to the loweſt places, unleſs mingled with it by agitation or long ſtanding. Thus, if a jar of fixed air is inverted from ſome little height over a burning taper, enough of it falls unmixed upon the taper to extinguiſh it. The weight of this gas is, in all circumſtances of preſſure and temperature, to that of common air very nearly as three to two; hence its ſpecific gravity will be about .001806, and the weight of a cubic inch at 60° therm. and 29.5 inch bar. will be about .456 of a grain.

This gas alſo combines readily with water and many other ſubſtances, as will be preſently mentioned. Its combinations with the alkalies, earths, and metals, are called *carbonats*.

Carbonic acid gas is procured, for experiment, generally from lime-ſtone, chalk, marble, or any carbonat of lime, either by heat or by the action of an acid, almoſt any of which will diſlodge the carbonic from its baſes, and cauſe it to aſſume a gaſeous form. The mild alkalies may alſo be uſed for this purpoſe. The action of acids always produces an effervescence, or frothing at the ſurfaces of contact, owing to the rapidity with which the carbonic acid takes the form of a gas; and hence all ſtones that effervesce with acids may be preſumed (with but few exceptions), to conſiſt chiefly of carbonat of lime. To obtain carbonic acid gas in quantity and in a regular, uniform ſtream, put a number of ſmall lumps of marble or calcareous ſpar in any proper veſſel, pour on them ſulphuric or rather muriatic acid diluted, and receive the gas as it is generated. If it is collected over water, ſome will be loſt at firſt, owing to the abſorption of a portion by the water itſelf. Or elſe, put ſome dry chalk or marble, or eſpecially carbonat of magneſia, in an earthen retort and heat it to redneſs. The carbonic acid gas then comes off in abundance. When decompoſed by acids, a grain of marble will yield nearly a cubic inch of gas.

As all mixtures under the vinous fermentation, give out an abundance of this gas, this affords a ready way for procuring it, and ſubſtances under experiment may be immerſed in an atmoſphere of the gas by being ſimply ſuſpended over the fermenting vats of brewhouſes.

Carbonic acid gas is readily abſorbed by water; and thus the natural carbonated waters may be eaſily imitated. This fluid has a pungent, agreeable, briſk taſte, and bubbles vigorouſly, when expoſed to air, the more in proportion to the temperature. This abſorption is ſhewn in a very eaſy manner, ſimply by filling a phial with water, then diſplacing about half its contents, by throwing up the gas, and then preſſing the finger cloſe againſt the mouth, ſhaking the half-full bottle violently. It will then abſorb ſo much of the gas as to make nearly a vacuum within, which will be felt by a ſtrong external preſſure of the atmoſphere on the finger that ſhuts the communication. This abſorption is alſo equally promoted by ſubjecting the gas to ſtrong preſſure, when in contact with the water that is to abſorb it; and it is by the united action of preſſure and agitation that the manufacture of the carbonated medicinal waters (ſuch as the artificial Seltzer, and the like), is carried to ſuch great perfection.

Water, at about 50° temperature, will abſorb, by mere agitation, nearly its own bulk of carbonic acid gas; but by the combined action of preſſure and agitation, three times as much may be thrown in.

Mr. William Henry, in his valuable experiments on the abſorption of gaſſes by water, (Phil. Tranſ. for 1803,) has ſhewn that the quantity of gas abſorbed is (*ceteris paribus*), regulated by the purity of the gas; for, even if the gas itſelf is obtained unmixed with any other, ſome addition of atmoſpherical air muſt take place from the veſſels in which the experiment is made, and alſo from the water, which cannot be abſolutely purged of common air by boiling or any other method. Hence Mr. Henry found, that if 20 meaſures of nearly pure carbonic acid gas were agitated with 10 meaſures of water, full 10 meaſures of the gas would be abſorbed; but if 20 of the gas, mixed with 10 of common air, were agitated with the ſame quantity of water, only ſix meaſures could be taken up. Water alſo parts with a great proportion of its carbonic acid by mere expoſure to air, which independent of the circumſtance of removing the mechanical preſſure of corks, &c.; for Dr. Brownrigg found that the gas would not eſcape from Seltzer water, when in a cloſe bottle, though a looſe empty bladder ſupplied the place of a cork, and in which, therefore, the gas had ample room to expand itſelf; but a free communication with the air was neceſſary for this eſcape. The abſorption of the gas is inverſely as the temperature of the water; cold water abſorbing much more than warm. The diminution of abſorption, on raiſing the heat, Mr. Henry eſtimates at about $\frac{1}{14}$th of the whole for every ten degrees above 55°. With regard to the effect of preſſure, it appears that water, in all caſes, takes up as great a bulk of condenſed as of expanded gas, under ſimilar circumſtances of temperature.

Therefore, as the bulk of all aeriform bodies is inverſely as the preſſure to which they are expoſed, the quantity abſorbed is directly as the preſſure; that is, for example, if a preſſure of 30 inches of mercury will cauſe a certain bulk of carbonic acid to be abſorbed, a preſſure of 60 inches will cauſe a double abſorption.

The ſpecific gravity of water, holding its own bulk of carbonic acid, is about 1.0015. This gas is readily and almoſt totally again expelled by heat; hence, in the analyſis of mineral waters, the firſt ſtep to be in general purſued is the expulſion of the gaſſes which it may contain, by boiling for about ten or fifteen minutes.

Carbonated water ſhews its acid properties by changing the colour of litmus from blue to red. This it will do, according to Bergman, when the water contains as much as $\frac{1}{16}$th of its bulk of the gas. It is very conveniently ſhewn, in the way mentioned by Kirwan, that is, by adding, in a thin glaſs tube, or jar, about equal quantities of the carbonated water, and of litmus infuſion diluted, ſo that the blue is juſt diſtinguiſhable. The colour then becomes of a very dilute red, and is better remarked when compared with a ſimilar glaſs tube full of the ſame dilute litmus liquor and plain water. To ſhew that it is the carbonic and no other acid that produces this change, let ſome of the carbonated water be boiled ſtrongly for a few minutes, and then it will leave the blue unaltered.

But lime-water is a much more delicate teſt for carbonic acid, either gaſeous or liquid. When a gas is to be tried, nothing more is required than to ſhake it with lime-water, or with barytic or ſtrontian water, and the immediate mildneſs of the water will indicate the preſence of carbonic acid gas in almoſt every caſe.

But with liquid carbonated water, it ſhould be remembered, that though the firſt portion of carbonic acid will precipitate the lime from its ſolution in the form of white carbonat of lime or chalk, a greater portion of the acid will re-diſſolve the *carbonat of lime*. So that if a highly carbonated water and lime-water be mixed together at repeated portions, the mixture will firſt become turbid by the ſeparation of the carbonat of lime; then an additional quantity of carbonated water will make it again clear by re-diſſolving the carbonat; after which another portion of lime-water will again make it turbid, and freſh carbonated water again clear, and ſo on, in proportion to the mutual ſaturation and ſuperſaturation of the two ingredients. Therefore, as no error can ariſe from an exceſs of lime-water, the latter, to ſhew, in all caſes, the preſence of carbonic acid, ſhould be in equal quantity with the carbonated water. According to Bergman's valuable reſearches on carbonic (called by him *aerial*) acid, lime-water will detect by its cloudineſs as little as one cubic inch of the gas in 7000 grains of water, that is, where the weight of the gas is only $\frac{1}{14000}$th of the whole.

This gas is alſo readily and totally abſorbed from any gaſeous mixture by ſlight agitation with a ſolution of cauſtic or nearly cauſtic alkali. A much ſmaller quantity of alkaline ſolution will ſuffice than of lime-water, as the former may be made much more concentrated. This is often convenient; but it is not ſo palpable a teſt, as no cloudineſs or change of appearance in the alkaline ſolution enſues.

Carbonic acid, according to the modern ſyſtem of nomenclature, ſignifies an acid whoſe baſis is carbon; and hence that it is produced by the combuſtion or oxygenation of carbon or pure charcoal. It required the united efforts of many of the moſt eminent chemiſts to elucidate the nature of this important acid, and to ſhew that the very ſame ſubſtance which exiſted as a large component part of all calcareous ſtones, and was given off abundantly by many of the natural mineral waters, was alſo the ſole product of the combuſtion of charcoal, and all carbonaceous matters. The full diſcovery and proof of this fact are due to Lavoiſier, who made the elementary experiment of burning a given weight of charcoal in oxygen gas of known purity, (no other ſubſtance being introduced than a very minute portion of phoſphorus to begin the combuſtion,) and found the product of the combuſtion to be this acid gas, the weight of which, when removed by cauſtic alkali, correſponded very exactly with the loſs of charcoal and oxygen. Very little actual diminution of bulk takes place at firſt in this combuſtion, ſince the product is itſelf a gas, and not a liquid, as happens after the combuſtion of ſulphur, phoſphorus, &c. and therefore it is not till cauſtic alkali or lime-water is introduced that the production of the carbonic acid, and conſequent loſs of oxygen, are made apparent. From this elementary experiment, Lavoiſier infers, that carbonic acid is compoſed of about 28, by weight, of charcoal, and 72 of oxygen, and the reſults of ſubſequent inquiries nearly, if not abſolutely, confirm the accuracy of this ſtatement.

Carbonic acid is at its higheſt ſtate of oxygenation, and is the only ſtate in which it has acid properties. United with leſs oxygen it forms the *carbonous oxyd* as noticed in the laſt article, in which, alſo, the partial diſoxygenation of carbonic acid and conſequent production of the carbonous oxyd are deſcribed.

Carbonic acid has been *completely* diſoxygenated (that is, reduced to black pulverulent charcoal) by only one ſubſtance, namely, by phoſphorus. This diſcovery was made by Mr. Tennant, and was followed by other valuable experiments by Dr. Pearſon. (Phil. Tranſ. for 1791-2.)

From the well known fact that phoſphorus cannot be made by diſtilling phoſphat of lime and charcoal, the latter not having the power of decompoſing this acid when united with lime, Mr. T. inferred that the united actions of phoſphorus and lime might be ſufficient to decompoſe carbonic acid by a ſtronger affinity with its oxygen. He accordingly put ſome phoſphorus into a coated glaſs tube cloſed at one end, and over the phoſphorus ſome powdered marble. The open end of the tube was then alſo cloſed, except a very ſmall aperture, to prevent the free acceſs of the external air, and the tube was then heated red hot for a few minutes. When cold and broken it was found to contain a black powder conſiſting of true charcoal mixed with both phoſphat and phoſphuret of lime, together with ſome undecompoſed marble. In this experiment the only ſource of the black carbonaceous powder can be the carbonic acid of the marble, which appears to have been decompoſed by complicated affinities, namely by that of part of the phoſphorus for the oxygen of the carbonic acid, of the reſt of the phoſphorus for the lime forming the phoſphuret of lime, and alſo by the phoſphoric acid (as ſoon as formed) for another portion of the lime forming the phoſphat of lime. Or, in other words, the carbonat of lime muſt undergo two diſuniting proceſſes before the charcoal can be produced, namely, the carbonic acid muſt be ſeparated from the lime to which it has a certain affinity, and alſo the oxygen of the carbonic acid muſt be ſeparated from the carbon which is its baſe. The lime is detached from its union with the carbonic acid by the united affinities of part of the phoſphorus for lime, and alſo of the phoſphoric acid, when formed, for the lime. On the other hand, the carbonic acid is decompoſed by the direct affinity of phoſphorus for oxygen, which is great, but however of itſelf leſs than that of carbon for oxygen, ſince, in the common diſtillation of phoſphorus, it is produced by decompoſing phoſphoric acid with charcoal. Therefore the decompoſition of carbonic acid here produced is the reſult of combined affinities, and could only be effected in this manner.

Dr. Pearſon decompoſed carbonic acid by a ſimilar proceſs, but with phoſphorus and carbonat of ſoda inſtead of carbonat of lime. Sufficient quantity of the black powder was procured in both caſes to prove that it was genuine charcoal, and yielded carbonic acid again on combuſtion with nitre.

Many liquids abſorb carbonic acid with apparently as much eaſe as water, ſuch as alcohol, oil, &c. but ſuch mixtures ſeem to produce no remarkable chemical change.

The affinity of carbonic acid with the alkalies, earths, and metals, is ſo weak that it may be diſplaced by every other acid, the boracic excepted. This weakneſs of affinity is doubtleſs much owing to the tendency which it has to aſſume a gaſeous form as ſoon as diſengaged.

The order of the affinities of this acid in the liquid way for the alkalies and earths is barytes, ſtrontian, lime, potaſh, ſoda, magneſia, and ammonia. With regard to the two latter indeed, the force of affinity is ſo nearly balanced that each ſubſtance will partially decompoſe the carbonat of the other according to the temperature. Thus at a higher heat the ammonia, from its increaſed tendency to volatilization, loſes much of its force of affinity with ſolid or liquid baſes, and then its carbonat is decompoſed by magneſia, which no heat can volatilize; but in a low temperature the affinity of the ammonia prevails and it decompoſes the magneſian carbonat, though very imperfectly.

As the carbonic acid quits every ſubſtance in a high heat its relative affinities in the dry way cannot be aſcertained.

Carbonic *acid*, in *Agriculture*, an acid that abounds in nature, and is moſtly found in the form of an aeriform fluid, or gas. See Carbonic *acid*.

The author of the "Philoſophy of Gardening" remarks, "that when vegetable ſubſtances are decompoſed by fermentation, there is a quick union of oxygen and carbon; and this carbonic acid gas, called formerly fixed air, riſes up in vapour, and flies away. But where this proceſs goes on more ſlowly, as in a dunghill lately turned over, or in black garden mould lately turned over and thus expoſed to the air; much of which remains in the cells, or cavities of the hot-bed, or border, this carbonic acid is ſlowly produced, and is abſorbed by vegetable roots, he ſuppoſes, in its fluid ſtate, or diſſolved in water before it acquires ſo much heat as to riſe in the atmoſphere in the form of gas." This carbonic gas, in its fluid ſtate, or diſſolved in water, not in its aerial or gaſeous ſtate, is, he conceives, the principal food of plants; becauſe their ſolid fibres conſiſt principally of carbon, and their fluids of water, as is evident from their analyſis.

Carbonic *earth*, or *ſoil*, that ſort of earth, or ſoil, in which there is a conſiderable portion of decayed vegetable matter. Boggy and other wet kinds of lands, where any coarſe vegetable productions have been ſuffered annually to become putrid, are moſtly of this kind; and likewiſe ſuch grounds as have been much enriched by manures, ſuch as thoſe of old gardens. The ſurface ſtratum of lands in general partakes of this nature. See Carbon

CARBONNE, in *Geography*, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the diſtrict of Muret; 7 leagues S. of Toulouſe. The place contains 1825, and the canton 8676 inhabitants; the territory comprehends 202½ kiliometres, and 13 communes.

CARBU, a town of Italy, in the ſtate of Genoa, ſeven miles W.N.W. of Finale.

CARBULA, or Carbulo, in *Ancient Geography*, a town of Spain, in the department of Corduba, according to Pliny.

CARBUNCLE, in *Heraldry*, a charge, or bearing, conſiſting of eight radii, or ſpokes; four whereof make a common croſs, and the other four a ſaltier. Some call theſe radii *battons*, or *ſtaves;* becauſe round, and enriched with buttons, or pearled, like pilgrims' ſtaves; and frequently tipped, or terminated with fleurs-de-lys. Others blazon them, royal ſceptres placed, in ſaltier, pale and feſſe.

Carbuncle, in *Mineralogy*. See Spinell.

Carbuncle, *Carbunculus*, alſo denotes a ſort of ſandy matter found in Hetruria, formed of a hard earth of the ſame name, concocted in the viſcera of the mountains, by the heat of the ſubterranean vapours.

Pliny and Varro ſpeak of the carbunculus, as a peculiar kind of hot, dry, lean ſoil.

Carbuncle, in *Surgery*, a roundiſh, hard, livid, and painful tumour, quickly tending to mortification, and (when it is malignant) connected with extreme debility of the conſtitution. See Anthrax. When this complaint is ſymptomatic of the plague, a peſtilential bubo uſually attends it. See Plague. The carbuncle is ſeated deeply, in parts provided with cellular membrane; and therefore does not ſoon diſcover its whole dimenſions, nor the ill digeſted matter it contains. As this tumour is commonly a ſymptom of depraved health, our chief attention ſhould be directed to the re-eſtabliſhment of the patient's ſtrength, rather than to the local treatment of the carbuncle. See the directions given under the article Gangrene, which will generally apply to the caſe in queſtion.

Bleeding, purging, and other antiphlogiſtic means can very ſeldom be admiſſible in the treatment of carbuncles; but, on the contrary, we ſhould ſupport the patient's ſtrength by powerful tonics, fermented liquors, country air, and anti-putreſcent vegetables; while the tumour itſelf may be poulticed, and fomented with anodyne decoctions, till it be fit to be opened by the lancet.

CARBUNCULATION, the blaſting, or ſcorching of the new-ſprouted buds of trees, or plants, either by exceſſive heat, or exceſſive cold.

It happens chiefly in the ſpring and autumnal ſeaſons, when vegetables being covered with dewy vapours, a ſudden cold comes on them, which congealing thoſe vapours, the nutritious juice of the plant is coagulated, and the texture of its fibres deſtroyed.

CARBUNCULUS, in *Ornithology*, eſcarboucle, and carbuncle humming-bird. See Trochilus Carbunculus.

CARBURET, in *Chemiſtry*, is a combination of charcoal with any other ſubſtance. Thus, *carburetted hydrogen* is hydrogen holding carbon in ſolution. The only other carburets hitherto certainly known are, *carburetted ſulphur*, *carburetted iron*, and *carburetted copper*.

CARCA, in *Ancient Geography*, a town of Spain, placed by Ptolemy in the interior of the country, inhabited by the Baſtitani.

CARCAJOU, in *Zoology*, the name of an animal of the badger kind, ſaid to be firſt deſcribed by M. Saraſſin in Hiſt. Acad. Soc. 1713: he ſpeaks of it as a ſmall quadruped, but very ſtrong and furious. This is the *carcajou* of Buffon, *American badger* of Pennant, and ursus *Labradorius* of Linnæus and Schreber, being found chiefly in the Labradore country, North America.

CARCAMOUSSE, in *Military Language*, a ram, a large wooden machine, having one end fortified and covered with iron, which the ancients made uſe of at ſieges for battering walls. It is alſo the name of a large machine of wood, uſed at preſent for driving piles into the ground. Under Charles the Simple, this name of carcamouſſe was given to the ram.

CARCANO, John Baptist, in *Biography*, born at Milan in 1538, was a favoured diſciple, and inmate of Fallopius, and profited ſo well by his inſtructions, as to be thought worthy of being coadjutor to that great anatomiſt, when he was only three or four and twenty years of age. On the death of Fallopius in 1563, Carcano was invited to Pavia, where he lectured with great applauſe. In the courſe of his diſſections, he diſcovered ſeveral errors in the deſcription of the heart and other parts of the body in the works of the old anatomiſts, which neither Veſalius nor Fallopius had detected. His works are, "Libri duo Anatomici; in altero de cordis vaſorum in fœtu unione pertractatur, in altero de muſculis palpebrarum atque oculorum motibus deſervientibus accuratè diſſeritur," Ticini, 1574, 8vo. In the firſt there are accurate deſcriptions of the foramen ovale, ſo called ſince from his account of it, and of the ductus arterioſus, which had been omitted, or erroneouſly deſcribed by Veſalius and Fallopius. In the ſecond he deſcribes the muſcles of the eyes and eye-lids, and the puncta lacrymalia, correcting here alſo ſome errors into which his maſter and former anatomiſts had fallen. "De Vulneribus Capitis," Mediol. 1584, 4to. In this work the author has collected all that was worthy notice on the ſubject in earlier writers, and added much from his own practice. "Exenteratio Cadaveris illuſt. Cardinalis Borromæi," 1584, 4to. Douglas Bibliog. Haller Bib. Anat. et Chirurg.

Carcano, Achilles, born at Milan in 1556, received the rudiments of his education under his father, an eminent ſurgeon in that city. He was afterwards admitted of the univerſity, and having taken his degree of doctor in medicine, went to Pavia, where he was engaged in teaching the practice of medicine. He died at Milan in 1588. His only work is an edition of the aphoriſms of Hippocrates, digeſted under proper heads, with practical obſervations, printed 1581, 8vo. Ticini. Haller Bib. Med.

CARCANOSSI, in *Geography*, a province of Madagaſcar to the ſouth of the river Metanengha.

CARCANTIA, in *Ancient Geography*, a place of Italy in Inſubria, on the route of the Gauls in their paſſage over the Cottian Alps. Anton. Itin.

CARCAPULI, in *Botany*, Bauh. hiſt. 1. p. 137. Rai. hiſt. 1661. *Cambogia gutta*. See Gamboge and Garcinia.

CARCAR, in *Geography*, a town of Spain, in Arragon, on the Ega; 3 leagues from Calahorra.

CARCARA, a town of Italy, in the duchy of Montferrat, on the river Bormia; 12 miles E. of Ceva.

CARCARAN, or Carcaravat, a river of South America, in Paraguay, which diſcharges itſelf into La Plata.

CARCARIAS Canis, in *Ichthyology*, a ſynonymous name of one or two different ſpecies of the ſhark tribe among old writers; ſometimes applied to squalus *galeus*.

CARCARIOLA, in *Geography*, a town of Naples, in the province of Abruzzo Citra; 22 miles W. of Aquila.

CARCASE, the corpſe, or body of a dead animal. The carcaſe of a fowl, capon, partridge, leveret, rabbet, &c. is what remains thereof, after the four members, or limbs, viz. the legs and wings, have been cut off.

CARCASE, in *Architecture*, is the ſhell or ribs of a houſe; containing the partitions, floors, rafters, &c. made by the carpenter, &c. The carcaſe is otherwiſe called the FRAMING.

CARCASO, in *Ancient Geography*, now *Carcaſſone*, a town of Gallia Narbonnenſis, belonging to the Volſci Tectoſagi, according to Pliny. Cæſar, in the third book of his "Bell. Gall." ſays, that this town furniſhed him with troops at the time of his war in Gaul.

CARCASS, in French CARCASSE, in *War*, is ſometimes a hollow caſe formed of ribs of iron, and covered over with pitched cloth, &c. about the ſize of a ſhell; and ſometimes is entirely of iron, like a ſhell with two, three, or four holes in it for the fire to blaze through. Carcaſſes are filled with various matters and combuſtibles for the purpoſe of ſetting fire to houſes when thrown out of mortars. They were formerly of an oval form, made of iron bars, and filled with a compoſition of mealed powder, ſaltpetre, ſulphur, broken glaſs, horn-ſhavings, pitch, turpentine, tallow, and linſeed oil, covered with a pitched cloth. They were primed with mealed powder and quick match. The flights, however, of the oblong ones were ſo erroneous and uncertain, that they have been totally laid aſide; and none but the round ones are uſed at preſent. The following is nearly the manner of preparing them.

Boil 12 or 15 lb. of pitch in a glazed earthen pot, or veſſel; mix with that 3 lb. of tallow, 30 lb. of powder, 6 lb. of ſaltpetre, and as many ſtopins as can be put in. Fill the carcaſs before the compoſition is cold, to do which, ſmear your hands with oil, or tallow, and fill the carcaſs one third full with the ſaid compoſition. Then put in loaded pieces of muſquet or piſtol barrels, or loaded grenades, filling up the intervals between theſe with part of this compoſition, and cover the whole over with coarſe cloth well ſewed together, keeping it as nearly as poſſible in a round or globular figure. Then put it into the carcaſs, having a hollow top and bottom with bars running between them to hold them together, and compoſed of four ſlips of iron joined at top, and fixed at the bottom at equal diſtances to a piece of iron, which together with the hoops, when filled, form a complete globular body. When it is quite finiſhed, and cold, it muſt be ſteeped in melted pitch, and then inſtantly immerſed in cold water. Laſtly, bore three or four holes at top, and fill them with fuze-compoſition, covering them with pitch until the carcaſs is going to be uſed. Carcaſſes are thrown out of mortars, and weigh from 50 to 230 lb. according to the mortars employed for throwing them. A carcaſs for the ſea-ſervice differs from a common ſhell of the ſame ſize only in the compoſition it is filled with, and the four holes in it, from or through which it burns or blazes when fired.

The following is a Table of experiments that were made with round caſe carcaſſes at an elevation of 45°.

|  | Nature or ſize of mortar. | Weight of the carcaſs. |  | Quantity of powder. |  | Time of flight in ſeconds. | Time of burning in minutes and ſeconds. |  | Length of priming. | Range. | Remarks. |
|---|---|---|---|---|---|---|---|---|---|---|---|
| No. |  | lb. | oz. | lb. | oz. | ſec. | min. | ſec | inches. | feet. |  |
| 1 | 10 | 62 | 13 | 0 | 8 | 6 | 3 | 0 | $2\frac{7}{10}$ | 390 | Burnt well in general. Fired from 7 to 9 o'clock in the morning. There was a good light. |
| 2 | 10 | 64 | 12 | 0 | 12 | 8 | 3 | 12 | $2\frac{7}{10}$ | 774 |  |
| 3 | 10 | 70 | 0 | 1 | 0 | 10 | 3 | 40 | $2\frac{7}{10}$ | 882 |  |
| 4 | 10 | 71 | 12 | 1 | 4 | $11\frac{1}{2}$ | 4 | 0 | $2\frac{7}{10}$ | 1332 | Fired from 2 to 4 o'clock in the morning. It was very dark. Gave a very good light. |
| 5 | 10 | 72 | 0 | 1 | 12 | 13 | 4 | 18 | $2\frac{7}{10}$ | 1815 |  |
| 6 | 10 | 68 | 10 | 2 | 0 | 14 | 4 | 45 | $2\frac{7}{10}$ | 2043 |  |
| 7 | 8 | 33 | 7 | 0 | 6 | 6 | 3 | 4 | $2\frac{7}{10}$ | 411 | Fired from 10 o'clock at night to 2 in the morning. Had a very good effect. |
| 8 | 8 | 36 | 12 | 0 | 10 | 8 | 3 | 20 | $2\frac{7}{10}$ | 963 |  |
| 9 | 8 | 35 | 8 | 0 | 14 | 12 | 5 | 0 | $2\frac{7}{10}$ | 1344 |  |
| 10 | 8 | 34 | 14 | 1 | 0 | 14 | 3 | 40 | $2\frac{7}{10}$ | 1680 |  |
| 11 | 8 | 32 | 12 | 1 | 4 | 13 | 5 | 10 | $2\frac{7}{10}$ | 1908 |  |

The following is a Table of experiments made with thirteen inch round iron carcaſſes fired from a thirteen inch ſea-ſervice mortar at Woolwich in 1773.

| Empty. |  |  | Full. |  |  | Powder. |  | Elevation. |  | Range. | Remarks. |
|---|---|---|---|---|---|---|---|---|---|---|---|
| cwt. | qr. | lb. | cwt. | qr. | lb. | lb. | oz. | deg. | min. | feet. |  |
| 1 | 2 | 27 | 1 | 3 | 12 | 30 | 0 | 45 | 0 | 8700 | One ſmall piece burſt from the carcaſs and fell at the diſtance of 4500 feet; the other piece contained the compoſition. The two laſt did not break. |
| 1 | 3 | 1 | 1 | 3 | 14 | 30 | 0 | 41 | 0 | 9000 |  |
| 1 | 3 | 3 | 1 | 3 | 6 | 30 | 0 | 42 | 0 | 10200 |  |
| 1 | 1 | 4 | 1 | 3 | 17 | 30 | 0 | 42 | 30 | 10500 |  |

Carcaſſes, it is ſaid, were firſt made uſe of by the biſhop of Munſter at the ſiege of Groll, in 1672, where the duke of Luxemburg commanded.

CARCASSEN, in *Geography*, a town of Spain in Valentia, ſeated in the valley of Xucar.

CARCASSONE, anciently *Carcaſo*, a town of France, and principal place of a diſtrict in the department of the Aude, formerly the capital of a county called Carcaſſez, and before the revolution the reſidence of a governor, and the ſee of a biſhop, ſuffragan of Narbonne. It is divided by the river Aude into the upper and lower town, both of which are encompaſſed by a wall. The former is ſituate on an eminence, and has a caſtle which commands the whole town, and an ancient cathedral. The lower town is more conſiderable, and is regularly built in the form of a large ſquare. Its ſtreets are ſtraight, and interſect one another at right angles, and they lead to a large ſquare in the centre, where is a fountain formed of rock-work, and having on the top of it a figure of Neptune. The quays are ornamented with rows of trees, which form agreeable walks. The town has a conſiderable manufacture of cloth; and the adjacent country, which is mountainous, abounds with olive-trees and vines, and affords a fine marble, called "the marble of Languedoc." Carcaſſone ſuffered very much on occaſion of the cruſade that was undertaken againſt the ALBIGENSES in the beginning of the 13th century; and after having been inveſted by Simon de Montfort, who directed and commanded the military operations of the church, A.D. 1209, was allowed to capitulate on condition that the inhabitants ſhould evacuate it in a ſtate of nudity; nor was Agnes the viſcounteſs, though young and beautiful, exempted from this ignominious and ſhocking puniſhment.

The place is ſaid to contain 15,219, and the canton 18,516 inhabitants; the territory includes 142½ kiliometres and 8 communes. It is 12 leagues W. from Narbonne, 19 S.E. from Touloufe, 15 N.E. from Foix, and 160 S. from Paris. N. lat. 43° 11′. E. long. 2° 25′.

CARCATHIOCERTA, in *Ancient Geography*, a town of Aſia, in Greater Armenia, near the Tigris, according to Pliny. It was a royal city of the country called "Sophena," according to Strabo.

CARCATTY, in *Geography*, a town of the iſland of Ceylon; 35 miles N.W. of Trincomaly.

CARCAVEE, a town of Iſtria; 5 miles S.S.W. of Capo d'Iſtria.

CARCAVELOS, a village of Portugal in the vicinity of Liſbon, between which and the town of Oeyras is produced the ſweet wine, called in England Liſbon, in Germany Portugieſwein, and in the country itſelf wine of Carcavelos. The vineyards are incloſed in quintas, on a gentle declivity towards the ſea, and the muſt is generally ſent to Liſbon, where it is made into wine. This wine which is generally white, and beſt of that colour, is drank in the country in great perfection, nor can the adulterated liquor ſold in foreign countries under that name be compared to it.

CARCAVI, PETER DE, in *Biography*, was born at Lyons, and became counſellor to the parliament at Toulouſe. He was the friend of Fermat, who at his death left to him the care of his writings; and after the death of Merſennus he correſponded with Des Cartes, with whom he became acquainted in 1646. At the time of his correſpondence, or about 1649, he was ſettled at Paris, where he became counſellor to the grand council, and keeper of the king's library till the death of M. Colbert. He was alſo the particular friend of Paſcal and Roberval. Interfering with ſome warmth in the diſpute that took place between the laſt of theſe mathematicians and Des Cartes, the correſpondence between him and Des Cartes was broken off. He was diſtinguiſhed by his *great* knowledge of books, antiquities, and medals. On the eſtabliſhment of the French Academy in 1666, he was appointed geometer. He died at Paris in 1684. Gen. Biog.

CARCERES, in *Antiquity*, were the liſts, or barriers of the circus, within which the horſes were confined, till the ſignal was given by the magiſtrate for ſtarting.

The word is Latin, ſuppoſed to be formed *a coercendo*, as they ſerved as a reſtraint to the horſes ready to run. In the olympic games a ſtretched cord, called "balbis" ſerved this purpoſe. Livy ſays, that the Romans diſuſed the balbis of the Greeks, A. U. C. 425, and conſtructed carceres in their room.

The number of carceres was twelve. In the early days of Rome they were made of wood, which Claudius afterwards changed for marble. They were kept faſt with bolts, ſuſtained by ropes, which, the moment the ſignal was given, flew open all at once. Some think that only four were uſed at a time. Suet. in Claud. cap. xxii. n. 6. See CIRCUS *maximus*.

CARCHA, in *Ancient Geography*, *Kark* or *Eſki-Bagdad*, a town of Aſia, in Aſſyria, ſeated on the eaſtern bank of the Tigris, about 50 leagues S. of Niniveh, and 25 N. of Bagdad.

CARCHEMISH, or CARCAMIS, a town of Aſia, ſeated on the Euphrates and belonging to the Aſſyrians. Whilſt the Aſſyrians were defending themſelves againſt the Scythians, who had conquered the whole of Upper Aſia, Pharaoh-Necho, king of Egypt, laid hold of this favourable opportunity for recovering the city, which was then ſubject to the king of Aſſyria. The garriſon, which he left in it, was cut in pieces by Nebuchadnezzar in the fourth year of Jehoiakim, B. C. 606 (2 Chron. xxxv. 20. 2 Kings xxiii. 29.). Carchemiſh is probably the *Cercuſium*, *Circeſium*, or *Circeium* of profane authors, ſeated in the angle formed by the junction of the Chaboras or Chebar with the Euphrates.

CARCHERD, in *Geography*, a town of Perſia, in the province of Choraſan; 45 miles N.W. of Herat.

CARCHI, in *Ancient Geography*, a people of Aſia in Media, according to Polybius.

CARCHI, in *Geography*, a ſmall fertile iſland in the Mediterranean ſea, near that of Rhodes.

CARCICIS *portus*, in *Ancient Geography*, *Caſſis*, a port of Galiia Viennenſis, nearly S. E. of Marſeilles, and N. W. of *Cithariſtæ portus*.

CARCINA, or CARCINES, a navigable river of Italy, in the country of the Brutii, between the promontories *Cocinthium* and *Lacinium*, according to Pliny.

CARCINE, or CARCINITIS, the name of a town nearly W. of the iſthmus which joins the Crimea to the continent, at the mouth of the ſmall river Calanza.

CARCINITIS *Sinus*, a gulf of the Euxine ſea, between the Tauric Cherſoneſus and Scythia. Strabo calls it *Tamyragus* and *Carcinites*. It was afterwards called Necro-Pyla.

CARCINIUM *Opalinum*, in *Zoology*. See DAGYSA.

CARCINOMA, in *Surgery*, the ſame as a *cancer*, which was named καρκίνωμα by the Greeks, from καρκίνος a crab, and νεμω I gnaw or corrode; hence comes the word *carcinomatous* or *cancerous*. See CANCER.

CARCINUM, in *Ancient Geography*, a town of Italy in Brutium, probably the ſame with "Carcinus," placed by Pomponius Mela in the gulf of Squillace.

CARCOMA, a port-town of Africa, S.W. of the promontory *Apollinis.* Ptolemy places it immediately after *Cartenna* and *Carepula.*

CARCOTÆ, a people of Sarmatia in Europe, who ininhabited that part of the country which was in the vicinity of the *Carbones*, according to Ptolemy.

CARCRAIG, in *Geography*, a ſmall iſland of Scotland, in the Frith of Forth; 7 miles S. E. of Dumferline.

CARCUNAH, a town of Africa, in Ethiopic Barbary.

CARCUS, in *Ancient Geography*, a name given by Ptolemy to an iſland of the Indian Ocean, which he places near Taprobana.

CARCUVIUM, a place of Spain, in Luſitania, according to the Antonin. Itin.

CARD, in the *Manufactures*, an inſtrument conſiſting of a block of wood, beſet with ſharp teeth, ſerving to arrange the hairs of wool, flax, cotton, and the like; of which there are different kinds, as ſtock-cards, hand-cards, wool-cards, tow-cards, &c. The word ſeems formed from the Latin *carduus (fullonum)* which denotes the fuller's teazle; a kind of thiſtle whoſe head is uſed to ſmooth and range the nap of cloth, &c. Skin. Etym. Angl. in voc.

They are made in the following manner. A piece of thick leather, of the ſize of the propoſed card, is ſtrained in a frame, and then pricked full of holes, into which are inſerted the teeth or pieces of iron wire. The leather is then raiſed by the edges to a flat piece of wood, in the form of an oblong ſquare, about a foot long and half a foot broad, with a handle placed in the middle of one of the longer ſides. The method of making the teeth is as follows: when the wire is drawn of the intended ſize, a number of wires is cut into proper lengths by means of a gage, and then doubled in a tool contrived for that purpoſe; after which they are bent into a proper direction by means of another tool, and they are then fixed in the leather. See CARDING, CLOTH, and COTTON *Manufacture.*

Cards for wool in England, may not be imported, nor the wire taken out of old cards, to be put into new leather and boards, in order for ſale; upon forfeiture thereof, or of the value, if not ſeized; but may be amended for the proprietor's own uſe, or for tranſportation only.

CARD-*playing*. See CARDS.

CARDALENA, in *Ancient Geography*, a country of Arabia Felix. Pliny.

CARDAMENE, or CARDAMINA, an iſland of the Arabic gulf on the coaſt of Ethiopia. It was ſeparated by the iſle of the Magi from the Trogloditic territory, according to Ptolemy and Pliny.

CARDAMILIA, in *Geography*, a town of European Turkey, in the Morea; 14 miles S. W. of Miſitra.

CARDAMINDUM, in *Botany*, Few. peruv. 3. tab. 8. and 2. tab. 42. See TROPÆOLUM *majus* and *peregrinum.*

CARDAMINE, (*καρδαμίνη*, a diminutive of *καρδαμον*, the Greek name of the water-creſs, the naſturtium of the old botaniſts; ſiſymbrium naſturtium of Linnæus.) Tourn. Cl. 5. §. 4. gen. 5. Linn. gen. 812. Schreb. 1088. Willd. 1237. Juſſ. 239. Vent. 3. 105. Gært. 833. Claſs and order, *tetradynamia ſiliquoſa.* Nat. Ord. *ſiliquoſæ*, Linn. *cruciferæ*, Juſſ. *cruciform* of Tournefort.

Gen. Ch. *Cal.* Perianth four-leafed; leaflets oblong-egg-ſhaped, obtuſe, ſomewhat ſpreading, gibbous, ſmall, deciduous. *Cor.* four-petalled, cruciform; petals inverſely egg-ſhaped, oblong, wide-ſpreading, ending in erect claws, which are twice the length of the calyx. *Stam.* Filaments ſix, awl-ſhaped; of theſe, two oppoſite ones are twice the length of the calyx, the reſt a little longer; anthers ſmall, heart-ſhaped, oblong, erect. *Piſt.* Germ ſlender, cylindrical, the length of the ſtamens; ſtyle none; ſtigma obtuſely headed, entire. *Peric.* Silique long, the ſhape of a compreſſed cylinder, two-celled, two-valved; valves opening from the baſe with a ſpring, and rolling ſpirally backwards. *Seeds* many, roundiſh.

Eſſ. Ch. Valves of the ſilique opening from the baſe with a ſpring, and rolling ſpirally backwards. Stigma entire. Calyx rather gaping.

Obſ. There is a variety of one ſpecies, in which the two ſhorter ſtamens are wanting.

* *Leaves ſimple.*

Sp. 1. C. *bellidifolia*, daiſy-leaved or alpine creſs. Linn. Sp. Flora Lapp. Ed. 2. 222. tab. 9. fig. 2. Flor. dan. tab. 20. Jacq. Miſc. v. 1. 148 tab. 17. fig. 2. "Leaves egg-ſhaped, quite entire, only a third of the length of the petiole." *Root* perennial, ſmall, ſomewhat woody. *Stems* ſcarcely two inches high, erect, ſimple, few-flowered, ſmooth. *Leaves* egg-ſhaped, ſmooth; radical ones on long petioles; ſtem ones nearly ſeſſile. *Flowers* in a terminal corymb; petals white, erect, twice as long as the calyx. *Silique* linear, obtuſe, ſmooth. Dr. Smith, Flora Brit. vol. ii. p. 697. Much obſcurity hangs over this ſpecies. Ray's C. pumila, bellidis folio, generally quoted as a ſynonym, Dr. Smith ſays, certainly does not belong to it, and is probably arabis ſtricta. The only real authority for its being a native of Great Britain is Dr. Withering, who had ſpecimens gathered wild in Scotland by Mr. Milne. All that he ſays of it is, that the root leaves are on long petioles, and that in its larger growth there are leaves on the ſtem, but rarely with petioles. Willdenow deſcribes two plants, nearly allied to each other, but, as he ſuppoſes, diſtinct ſpecies. One with the flowering ſtem not longer than the root-leaves, and either naked or with one or two leaves on long petioles; the other with the flower ſtem longer than the root-leaves, and with ſtem-leaves nearly ſeſſile. The former, a native of Lapland and Norway, he calls bellidifolia; the latter, a native of the Alps, he calls alpina. La Marck makes it an arabis, but it does not ſeem to be the arabis bellidifolia already deſcribed in this work. 2. C. *aſarifolia*, aſarabacca-leaved creſs, Linn. Sp. Pl. (Naſturtium montanum, aſari folio; Bocc. Sic. 5. tab. 3. Herm. Par. tab. 203. Rai hiſt. 816. Naſturtium alpinum, paluſtre rotundifolium, radice repente; Moriſ. hiſt. 2. p. 224.) "Leaves ſimple, ſomewhat heart-ſhaped." *Root* perennial, thick, ſending out numerous fibres. *Stems* about ſix inches high. *Leaves* petioled, a little ſcolloped, ſmooth. *Flowers* white. *Siliques* long, burſting at the leaſt touch when ripe. It poſſeſſes the qualities of ſcurvy-graſs in a greater degree than the other ſpecies of cardamine, and is often ſubſtituted for it. A native of Savoy, Tuſcany, &c. 3. C. *nudicaulis*, naked-ſtemmed creſs, Linn. Sp. Pl. Gmel. Sib. 3. p. 273. n. 43. "Leaves ſimple, lanceolate, ſcollop-toothed; ſtems naked." *Stems* about nine inches high. *Leaves* about three inches long, ſmooth, firm. *Siliques* ſlender, ſtriated, ſmooth, compreſſed between the ſeeds. A native of Siberia. 4. C. *nivalis*, Willd. Pallas. itin. 2. App. 4. 113. t. u. Germ. tom. 3. Pl. 17. p. 264. French. Tranſ. "Stem and root-leaves ſimple, oblong, toothed. Whole plant ſmooth. Root perennial. Root-leaves leſſened at the baſe into a petiole; ſtem-leaves ſeſſile. *Flowers* ſmall, white. Siliques reflexed. 5. C. *petræa*, Linn. Sp. Pl. "Leaves ſimple, oblong, toothed." This ſpecies is omitted by La Marck and Willdenow. Willdenow ſays it is a dubious plant, all the ſynonyms certainly belonging to arabis hiſpida. This, with reſpect to the Welſh and Scotch ſuppoſed ſynonyms, is confirmed by Dr. Smith. But on his authority we have retained the ſpecies; for he ſpeaks of the true Swediſh C. petræa of Linnæus in terms implying a ſatisfactory acquaintance with the plant, which we preſume is preſerved in the Linnæan herbarium. See Engliſh Botany, p. 469. The C. petræa of Lightfoot is there deſcribed, and figured as a new ſpecies under the name of C. haſtulata. But before the publication of the Flora Britannica, Dr. Smith was convinced that it is properly an arabis, and nothing more than a variety of arabis hiſpida, and of the Welſh plant miſcalled A. petræa, by Dillenius, Hudſon, and Withering. As ſuch it appears in the latter maſterly work. We now perceive that in the article arabis, we have been led into an error by following profeſſor Martyn, who thought the ſtricta of Hudſon, and the hiſpida of Linnæus, to be the ſame plant.

** *Leaves ternate.*

6. C. *reſedifolia*, Linn. Sp. Pl. (Naſturtium alpinum minus, reſedi folio; Bauh. pin. 104. Bocc. Muſ. 2. tab. 46.) "Lower leaves undivided; upper ones three-lobed and winged." *Root* biennial. *Stem* four or five inches high, ſlender, ſmooth, feeble. *Root-leaves* petioled, egg-ſhaped or ſpatula-ſhaped, entire. *Flowers* ſmall, white. *Siliques* ſlender, an inch long. It has ſome reſemblance to C. bellidifolia, but is conſtantly diſtinguiſhed by its winged ſtem-leaves, the terminal leaflet of which is larger than the others. Lam. A native of the Pyrenées, and of the Swiſs and German Alps. 7. C. *trifolia*, Linn. Sp. Pl. (Naſturtium alpinum trifidum; Bauh. pin. 104.) "Leaves ternate, obtuſe; ſtem almoſt naked." *Root* perennial. *Stems* ſeveral, ſix or ſeven inches high. *Root-leaves* ternate; leaflets a little angular, ſmooth, on a reddiſh petiole; *ſtem-leaves* one or two; leaflets narrow. *Flowers* white or reddiſh, in terminal cluſters. *Siliques* oblong, ſwollen with the ſeeds. A native of the Alps. 8. C. *ſcutata*, Willd. Thunb. Linn. Soc. Tranſ. 2. p. 399. "Leaves ternate, ſcutate, curled; ſtem almoſt naked." Perennial. A native of Japan. 9. C. *africana*, Linn. Sp. Pl. Tourn. 225. Vahl. Symb. 2. p. 77. (Naſturtium africanum; Herm. Par. 202. tab. 202. Pluk. Alm. 152. tab. 101. f. 5.) "Leaves ternate, acuminate; ſtems much branched." *Root* perennial. *Stems* nine inches or a foot high, erect, angular, hairy. *Leaves* on long petioles; leaflets petioled; the terminal one large, bluntly ſerrated, with ſcattered hairs about the veins. *Flowers* in corymbs or racemes, ſmall. *Siliques* an inch and half long, compreſſed. A native of Africa.

*** *Leaves winged.*

10. C. *chelidonia*, Linn. Sp. Pl. Pallas it. 3. 34. Lour. Coch. 398. (C. glabra, chelidonii folio; Tourn. Inſt. 224. Siſymbrium montanum latifolium: flore purpureo, Bar. ic. 156. Naſturtium Pyrenæorum, Herm. par. tab. 204.) "Leaves winged; leaflets in fives, gaſhed." *Root* perennial. *Stem* about nine inches high, nearly ſmooth, with many aſcending branches. *Leaflets*, eſpecially the terminal one, remarkably large, roughiſh, with ſhort hairs. *Flowers* large, purpliſh white, in terminal corymbs, lengthening into ſpikes; petals obtuſe or ſlightly emarginate, twice the length of the calyx. A native of the Pyrenées, Italy, and Siberia. 11. C. *thalictroides*, Willd. La Marck. Allion ped. tab. 57. fig. 1. (C. Plumieri; Vil. delph. 3. tab. 38. Naſturtium thalictri folio; Bocc. Muſ. 171. tab. 116.) "Leaves ſimple, ternate and winged; leaflets in fives, obtuſe, three-lobed." *Root* biennial. *Stems* about four inches high, ſlender. *Root-leaves* often ternate, on rather long petioles; terminal leaflet large, three-lobed; lateral ones irregularly egg-ſhaped; upper ſtem-leaves in fives. *Flowers* white, twice as long as the calyx. *Siliques* an inch long, ſlender, a little compreſſed, with eight or ten reddiſh ſeeds. A native of Piedmont and Dauphiny. 12. C. *macrophylla*, Willd. (C. chelidonia, Pal. it. 3, p. 34. Lepich. it. 1. p. 243. Siſymbrium pinnis ovatis ſerratis; Gmel. Sib. 3. tab. 62.) "Leaves winged; leaflets in fives or ſevens, egg-ſhaped, acuminate, unequally toothed." *Root* perennial. *Stem* a foot high. A native of Siberia. 13. C. *impatiens*, Linn. Sp. Pl. Eng. Bot. Pl. 80. "Leaves winged, ſtipulate; leaflets moſtly gaſhed, numerous; petals caducous; ſiliques erect." *Root* annual. *Stem* from twelve to eighteen inches high, remarkably ſtiff in its general habit, upright, more or leſs zig-zag, angular, hollow, ſmooth. *Leaves* alternate, nearly ſmooth, pale, extended at the baſe into two narrow, acute, ſingularly ciliated ſtipules not found in any other known ſpecies. *Flowers* ſmall, ſcarcely longer than the calyx, ſoon falling off, ſo that the plant has been thought to be without petals by Linnæus, Pollich, and Leers. A native of mountainous countries in ſeveral parts of Europe: about Matlock bath in Derbyſhire, Kilnſay cragg in Wharfdale, Yorkſhire, and plentifully in Weſtmoreland and Cumberland. It is ſcarce in the ſouth of England, but we gathered it laſt ſummer (1805) about the ſkirts of Wichberry wood, near Hagley, Worceſterſhire. 14. C. *parviflora*, Linn. Sp. Pl. "Leaves winged without ſtipules: leaflets lanceolate, obtuſe." *Root* annual. *Stem* ſhorter and leſs acutely angular than that of C. impatiens. *Petals* not caducous. *Siliques* erect, on horizontal peduncles. If two ſpecies have not been deſcribed by different authors under the ſame name, the leaflets of the upper ſtem-leaves vary in being either lanceolate or linear, perfectly entire, or a little toothed. It is now generally agreed that what ſeveral Engliſh and German botaniſts have taken for the parviflora is only a variety of hirſuta. A native of the ſouth of Europe, and Siberia. 15. C. *penſylvanica*, Willd. "Leaves winged; leaflets angularly toothed, obtuſe." Whole plant ſmooth. *Stem* erect, branched. *Leaflets* five or ſeven, with two large teeth on each ſide, giving them an angular appearance; thoſe on the higheſt leaves lanceolate, obtuſe, perfectly entire; the terminal one wedge-ſhaped, often trifid. *Siliques* narrow, erect. 16. C. *græca*, Linn. Sp. Pl. "Leaves winged; leaflets palmate, equal, petioled." *Root* annual. *Stems* five or ſix inches high, ſlender, branched. *Leaflets* from ſeven to thirteen, petioled, obtuſe, cut into three or four lobes, ſo as to appear palmate. *Siliques* from twelve to fifteen lines long, ſtraight, compreſſed, ſword ſhaped. A native of Sicily, Corſica, and the Grecian iſlands. 17. C. *hirſuta*, Linn. Sp. Pl. Hal. helv. n. 472. Eng. bot. 492. "Leaves winged; leaflets roundiſh, obtuſely angular, petioled." *Root* annual. *Stems* from three to twelve inches high, more or leſs zig-zag, clothed with ſcattered prominent hairs. In moiſt ſituations, and eſpecially in wet ditches, it riſes to eight or nine inches high, and has, we believe, conſtantly ſix ſtamens, and a ſtrong, rather unpleaſant ſmell and taſte. On dryiſh ditch-banks, and in fallow fields where it often occurs, its ſtem is much ſhorter, and its flowers have only four ſtamens, but its root-leaves are often very luxuriant, yet conſiderably milder, and are a good ingredient in a ſpring ſallad. Linnæus's ſpecific character was formed from the latter variety, whence Withering and Lightfoot miſtook the former for his parviflora, which has not been found in England; and Withering, after he diſcovered his error, thought it a new ſpecies which in the third edition of his Botanical Arrangement he called flexuoſa. Dr. Smith firſt determined them to be one ſpecies; and in confirmation of his judgment, we once found, in a kind of intermediate ſituation between wet and dry, ſeveral ſpecimens which had tetrandrous, hexandrous, and, in two or three inſtances, pentandrous flowers on the ſame plant. 18. C. *latifolia*, Willd. Vahl. Symb. 2. p. 77. "Leaves winged; leaflets five, ſomewhat angularly toothed, ſmooth." Whole plant ſmooth. *Stem* a foot high, ſimple, aſcending. *Leaves*

petioled, remote; leaflets oblong, unequal at their margin, with one or two teeth. *Flowers* in a corymb, numerous; peduncles an inch long; leaves of the calyx oblong, with a membranous edge; petals three times the length of the calyx, purple, ſlightly emarginate. Vahl." A native of Spain. 19. C. *pratenſis.* Ladies-ſmock, cuckow-flower, milk-maid. Linn. Sp. Pl. Curt. Flor. Lond. faſc. 3. tab. 40. Mart. Flor. inſt. tab. 40. Mart. Flor. inſt. tab. 95. Woodv. Med. tab. 30. Eng. bot. 776. Flor. Dan. tab. 1039. "Leaves winged: radical leaflets roundiſh, thoſe on the ſtem lanceolate." *Root* perennial. frequently toothed in ſome degree like that of coral-wort. *Stem* about a foot high. erect, ſtiff, ſimple. *Leaves* winged: root ones on long petioles, ſomewhat lyreſhaped; leaflets ſomewhat hairy; ſtem ones ſeſſile, alternate; leaflets ſmooth, channelled, generally entire. *Flowers* large, purpliſh or white, in a handſome terminal corymb, becoming double by cultivation. The colour and appearance of the flowers, the ſtyle rather more lengthened than in any other ſpecies of Cardamine, and above all a tendency of the leaves in wet ſhady places to bear bulbs, ſhew an affinity to the genus Dentaria or coral-wort. It has the ſame ſenſible qualities as the Siſymbrium naſturtium or water creſs, but in a very inferior degree. The flowers have obtained a place in the Britiſh Pharmacopœias on the authority of Sir George Baker, who recommended them to be taken internally in ſpaſmodic diſorders: they have even been ſaid to cure the epilepſy, but experience has not confirmed their reputation. They were preſcribed dried, which Dr. Smith obſerves, is not an advantageous ſtate for plants of this natural order. See Dr. Smith in Engliſh botany, and Woodville's Medical Botany. A native of wet meadows in many parts of Europe. 20. C. *amara*, bitter creſs. Linn. Sp. Pl. Curt. Flor. Lond. faſc. 3. tab. 39. Eng. Bot. 1000. "Leaves winged: root leaflets roundiſh, ſtem ones angularly toothed. Stem taking root at the baſe. Anthers violet-coloured." *Root* perennial, toothed. *Stems* procumbent at the baſe, and taking root in the mud, then upright, a foot high or more, ſomewhat zig-zag. *Leaves* nearly ſmooth. *Flowers* large, white or cream-coloured; ſtyle a little elongated and oblique. Found on the banks of rivers and brooks in ſeveral parts of Europe, but not ſo common as the preceding. On the banks of the Thames about London, of the Aire, Eure, and other rivers in Yorkſhire, King-ſtreet meadows near Norwich, and in Scotland. 21. C. *granuloſa*, Willd. Allion, pedem. (Naſturtium pratenſe odoratum radice granulis tuberoſa; Bauh. pin. 104.) "Root-leaves ſimple, roundiſh, on long petioles; ſtem-leaves winged; leaflets lanceolate; root granulated." *Root* perennial. *Stem* near half a foot high, erect, ſimple. *Root-leaves* entire, decurrent into the petiole: ſtem-leaflets obtuſe, entire. *Flowers* white; petals obtuſe, not emarginated, three times as long as the calyx. A native of meadows near Turin. 22. C. *virginica*, Linn. Sp. Pl. (Alyſſum, Gron. virg. 1. p. 170. Naſturtium burſæ paſtoris folio: Pluk. Alm. 231. tab. 101. fig. 4.) "Leaves winged; leaflets lanceolate, one-toothed at the baſe." *Root-leaves* ſpread into a circle; leaflets numerous, almoſt imbricated; ſtem-leaves few, often linear, entire. La Marck thinks it a true Arabis. A native of Virginia. 23. C. *ſarmentoſa*, Forſt. Flor. auſtral, n. 529. Found by Forſter in the iſland of Teautea in the South Seas.

The varieties of pratenſis and amara with double flowers may be readily propagated by parting the roots. They thrive beſt in ſhady ſituations.

CARDAMINE *alpina 3-minima*; Cluſ. hiſt. See LEPIDIUM *alpinum.*

CARDAMINE *puſilla ſaxatilis montana diſcoides;* Col. ecph. tab. 273. See LEPIDIUM *petræum.*

CARDAMOM: for the botanical characters, ſee AMOMUM *cardamomum* and *repens.*

The Cardamomums imported into Europe have been commonly diſtinguiſhed by the epithets, Majus, Medium, and Minus: but the ſpecies from which the two former are produced have been ſo imperfectly deſcribed, and their botanical hiſtory is ſo confuſed, that nothing deciſive can be ſaid concerning them. One of the three is probably the Cardamomum of Linnæus. The ſeeds of the *Minus*, which are now generally preferred for medical purpoſes, are ſaid by Sonnerat to be the produce of his A. repens, diſcovered by him on a mountain on the coaſt of Malabar, where it grows ſo plentifully as to ſupply all India with its ſeeds, and which on that account is called the monutain of Cardamoms. It is figured in Woodville's medical botany. They are brought to Europe in their natural huſk or pod, without which they would loſe a part of their flavour, and this is divided internally into three cells, in each of which are contained two rows of triangular ſeeds, browniſh on the outſide and white within. Theſe ſeeds have an extremely grateful aromatic ſmell, and when chewed, they impart a glowing warmth, and grateful pungency to the mouth. Their virtue is extracted both by alcohol and by water; the former giving a clear, the latter a turbid ſolution, both yellowiſh. The watery infuſion is highly mucilaginous. When theſe ſeeds, previouſly bruiſed, are diſtilled with water, a ſmall quantity of eſſential oil, about $\frac{1}{24}$th of the weight of the ſeeds, on an average, may be ſeparated, and in this ſeem to reſide all the aromatic qualities. It is of a pale yellow, very acrid, and ſtrongly ſmelling of the cardamom. The watery ſolution inſpiſſated yields a gummy-reſinous extract; the ſpirituous ſolution gives a reſinous extract much leſs in quantity. Neither of them are uſed.

Cardamom is one of the moſt grateful of the mild aromatics, and is uſed either to flavour other medicines, or as a ſtimulant and cordial. It agrees in general particularly well with dyſpeptic ſtomachs, and prevents the griping or nauſeating effects of many of the ſaline or other purgatives. A tincture is made of it both ſimple and compounded with carraway, cinnamon, and cochineal. Cardamom alſo enters the compoſition of ſome other aromatic preparations.

The ſeeds of the Cardamomum *Majus*, denominated alſo *Grana Paradiſi* or *Marieguetta, Greater Cardamon Seeds*, are hard reddiſh-brown angular ſeeds, much larger than the laſt-mentioned, about the ſize of radiſh ſeeds, generally imported without the huſk, from the Eaſt Indies. The ſmell and flavour of theſe are much leſs aromatic and grateful than thoſe of the leſſer ſeeds, and the taſte is hot, biting, and ſomewhat coarſe. It yields an eſſential oil not very acrid, but the watery and ſpirituous ſolutions are both highly pungent. Theſe ſeeds are but little uſed. See Lewis's "Materia Medica," and Woodville's Medical Botany.

CARDAMUM, in *Geography*, an iſland ſituate in the paſſage from Malacca to the ſtraits of Sincapore, or South end of Malacca ſtraits.

CARDAMYLA, in *Ancient Geography*, a town of Meſſenia, almoſt ſouth of Gerenia. It was one of the ſeven cities which Agamemnon wiſhed to preſent to Achilles. Pauſanias ſpeaks highly of the temple of Minerva and a ſtatue of Apollo "Carneus," the worſhip of whom was common to all the Dorians. This town was detached by Auguſtus from Meſſenia, but afterwards reſtored to its original maſters, the Lacedæmonians.

CARDAN, JEROM, in *Biography*, a voluminous philoſophical and medical writer, was born at Pavia Sept. 24th, 1501. His father, who was an eminent civilian, and a diſtinguiſhed

guiſhed ſcholar at Milan, took the charge of his education, in the early part of his life, and he particularly inſtructed him in mathematics, aſtronomy, and judicial aſtrology. He is ſaid not to have been born in wedlock, and in the account he gives of his own life he ſays, his mother, when pregnant with him, endeavoured to deſtroy him, by procuring abortion. She was a woman of ſtrong paſſions, and he probably derived from her that verſatility of diſpoſition, and violence of temper, which prevented his reaping the advantages he might have obtained from his genius and learning. At the age of 20 he entered the univerſity of Pavia, where he proſecuted his medical and philoſophical ſtudies with ſucceſs; he then went to Padua, in 1524, and in 1525 he took the degree of doctor in medicine. In 1529 he repaired to Milan, but was ſome time before he acquired any credit in his profeſſion; he was therefore reduced to great difficulties. His firſt appointment was that of profeſſor of mathematics, for which he was peculiarly qualified, and a few years after, viz. in 1539, he was admitted a member of the medical college in that city. This brought him into notice; but that he was not at peace with his brethren, appears by his two firſt publications, "De malo recentiorum Medicorum medendi uſu," Venet. 1536; and "Contradicentium Medicorum Libri duo," Lyons, 1548: in the firſt he ſeverely cenſures the practice of his cotemporaries; in the other the inconſiſtent and often contradictory accounts of the ſame diſeaſe, given by the moſt accredited writers, even among the ancients. In 1547 the king of Denmark, on the recommendation of Veſalius, invited him to accept the office of a profeſſor in the univerſity of Copenhagen, with a handſome ſalary; the offer was, however, refuſed, his time, we may preſume, being now more advantageouſly employed in practice. The reputation he had acquired in this way occaſioned his being ſent for to Scotland, about this time, to attend Hamilton, archbiſhop of St. Andrews, and brother to the regent, who was afflicted with aſthma, for which he had before tried the aſſiſtance of the phyſicians to the king of France, and the emperor, but without receiving any benefit. Cardan was more ſucceſsful, for by the end of about two or three months the archbiſhop was ſo much relieved, as to allow him to return to his own country, having received a large remuneration for his ſervices, and liberal offers to retain him in Scotland. On his return he paſſed through London, and is ſaid to have caſt the nativity of our king, Edward VI.; but we do not learn that he foretold the ſhort date of that monarch's exiſtence. At Milan he continued to reſide until 1559, his time being employed in the practice of medicine, and in teaching mathematics; from 1559 to 1562 he reſided at Pavia, being invited to accept the chair of profeſſor in medicine there; and from 1562 to 1570, at Bologna, where he filled a ſimilar office. He was now, for what cauſe we are not informed, thrown into priſon, but as he was ſoon liberated, we may ſuppoſe for no very ſerious offence; for though haughty and turbulent, he ſeems generally to have acted with ſufficient caution, as in whatever country he reſided, he was never ſeriouſly embroiled with the church or ſtate. It appears, alſo, that he had the faculty of attracting the notice, and procuring the friendſhip of thoſe perſons who, by their wealth or power, were moſt able to ſupport him, but by the waywardneſs of his diſpoſition he ſoon loſt their favour; hence he was always in a ſtate of indigence, which he relieved by ſending to the preſs ſome haſty effuſions, which had no more of his care than it coſt him to write them over. His works, therefore, which were collected after his death, and which fill ten maſſive folio volumes, conſiſt of ſuch a confuſed and undigeſted medley, that it would require more labour to put them into order than their intrinſic value would compenſate. Soon after being releaſed from priſon, he was ſent for to Rome, was made member of the college of phyſicians there, and aſſigned a penſion by the pope, which he retained to the time of his death, Sept. 21ſt 1576. It has been ſaid, that he ſtarved himſelf, in order to verify his own prediction of the time of his death; but this is improbable, becauſe he had long before acknowledged the failure of a ſimilar prediction. Thuanus, however, relates (lib. 62. p. 155.), that this fact was believed. Scaliger aſſerts it; and it is ſaid that his father died in the ſame manner, in 1524. Of him it is alſo ſaid, that his eyes were white; and that he ſaw in the night time, and could ſee without ſpectacles. Cardan "De Vita propria," p. 10. His reigning paſſion, if we believe his own account, was a deſire to acquire and communicate knowledge. Though a large portion of his life was paſſed in a ſtate of indigence, yet it did not appear to depreſs his ſpirits. He conſidered knowledge, of which he could not but be conſcious he had a large ſhare, as infinitely preferable to wealth. That he had no mean opinion of his own talents, or of his value to the community, ſeems evident by the following, ſuppoſed to have been written by himſelf, and intended as his epitaph:

> "Non me terra teget, cœlo ſed raptus in alto,
> Illuſtris vivam, docta per ora virûm.
> Quidquid venturis ſpectabit Phœbus in annis,
> Cardanus noſcet, nomen et uſque ſuum."

Vanity ſeems to have been with Cardan a predominant paſſion; for though with apparent frankneſs he recites the various adventures of his life, which ſhew the inconſtancy of his temper, he nevertheleſs conceals or palliates others, which are more diſhonourable. Addicted from his youth to judicial aſtrology, he pretends to deduce, by means of his ſkill in this ſcience, from the imaginary influence of celeſtial bodies, an apology for the licentiouſneſs of his opinions, and the eccentricities of his conduct. Such was his confidence in the concluſions furniſhed by this art, that in his treatiſe entitled "Explicatio Genituræ," or a calculation of nativity, he hazards many predictions concerning his own character and fortune, as well as others that related to Jeſus Chriſt. Whilſt he acknowledges a propenſity to irreligion, and advances ſome ſentiments that ſubject him to the ſuſpicion, if not to the direct charge, of atheiſm, he juſtly incurs the reproach of credulity and ſuperſtition. Having been accuſtomed, in conſequence of his father's inſtruction, at eight in the morning on every firſt of April to repeat a prayer and an Ave, he conceived that he was thus ſecure of obtaining any favour he ſhould aſk. From numerous prodigies that occurred, both ſleeping and waking, he pretended to infer what ſhould befal him; and he ſometimes ſeems to intimate, that, like Socrates, he was attended by a particular genius. Whilſt he boaſts of certain ſupernatural gifts that were beſtowed upon him, he muſt either be conſcious of wilful falſehood, or labour under a fanatical derangement of the underſtanding. Indeed, many have ſuppoſed that the preponderance of his imagination over his judgment did actually produce a ſpecies of inſanity. At the ſame time he affected ſingularities of dreſs and of behaviour, which ſeemed to indicate a degree of ſtudied artifice and impoſture. Under the influence of ſtrong paſſions, he was frequently betrayed, notwithſtanding his diſtinguiſhed abilities and erudition, into errors of judgment and irregularities of conduct, which tarniſhed the luſtre of his other laudable qualities, depreciated his character, and proved occaſions of perplexity and unhappineſs to himſelf. Theſe errors and irregularities aggravated, in no ſmall degree, his domeſtic diſtreſs. One of his ſons married a woman, deſtitute both of fortune and reputation, and determined to get rid of her by poiſon, he was convicted, condemned, and executed. Cardan attempted to juſtify this atrocious crime, on the ground of the wife's infidelity ; and pretends that the divine vengeance purſued the judges of his ſon for their ſentence againſt him. Another ſon behaved ſo ill, that he was obliged to impriſon, and at length to diſcard and diſinherit him.

In his medical profeſſion, Cardan was a ſagacious obſerver, and an induſtrious collector of facts ; but he was at the ſame time ſo boaſtful and ſo credulous, as to claim little or no confidence. He wrote on every branch of medicine ; but the volumes in which he treats of natural hiſtory, which give accounts of extraordinary cures, or deſcriptions of unuſual or preternatural productions, have been received with the greateſt favour, and have been the moſt frequently reprinted. His accounts, however, under theſe heads, muſt not be always implicitly admitted ; the greater part of theſe will be found in his treatiſe “De Varietate Rerum,” fol. Baſ. 1550, and again 1557. In his “Commentaries on the Aphoriſms of Hippocrates,” 1553, 4to. Patav. he records a caſe of a wound in the pericardium, in which the patient recovered, and of a perſon who loſt a portion of the brain, equal in ſize to a hen's egg. The man lived three years after the accident, but in a ſtate of fatuity. In his “Domo ruſtica,” Straſb. 1589, fol. he deſcribes the diſeaſes incident to cattle, with the manner of treating them. The 8th book of his treatiſe “De Subtilitate,” publiſhed 1550, is entirely botanical, and contains deſcriptions of numerous plants, then firſt introduced into Italy. In his “De Chinæ et Sarſaparillæ Radicibus,” 8vo. 1566, he deſcribes the manner of preparing the decoction of thoſe roots, and of adminiſtering them. In his “Opuſcula Artem Medicam exercentibus utiliſſima,” are ſome curious obſervations on the external application of cold water, which he had witneſſed in Scotland ; and extraordinary praiſes of the internal uſe of the pure element in fevers and other diſeaſes. His “Ars curandi parva, quæ eſt abſolutiſſima medendi Methodus,” Baſil, 1566, 2 vols. gives his general method of cure in diſeaſes, with many particular obſervations. His “Opus novum de Sanitate tuenda ac Vita producenda,” a poſthumous work, publiſhed in 1580, fol. contains a copious enumeration of articles of diet, and of directions for the mode of living, blended with much idle and ſuperſtitious matter. For an account of his other medical works, &c. ſee Haller Bib. Med. pract. chirurg. anat. et botan. or Eloy's Dict. Hiſtor. The cures which he undertook to perform by ſecret charms, or by the aſſiſtance of inviſible ſpirits, gained for him with the vulgar, the reputation of a magician ; but in reality they were only evidences of a mind infatuated by ſuperſtition.

In mathematical ſcience Cardan claims a tribute of more unreſtricted commendation. In algebra particularly he challenges the honour of having made ſome important diſcoveries ; though his pretenſions, as an original inventor, have been conteſted by Tartaglia. Theſe diſcoveries are contained in the 10th book of his Arithmetical writings, which was publiſhed at Milan in the year 1545. See ALGEBRA. In order to juſtify Tartaglia's prior claim, it has been alleged, that in a trial of ſkill with Antonio Maria del Fiore or Florido, he had diſcovered the general theory of equations of the third degree. The occaſion of it was this : Florido had received from his maſter Scipion Ferreo, about 30 years before, a general rule for reſolving a particular caſe of cubic equations, expreſſed by $x^3 + bx = c$. Preſuming on this diſcovery, Florido provoked Tartaglia into a conteſt, in which each ſhould propoſe to the other 30 queſtions ; and he who firſt reſolved them within a limited time, was to win the propoſed wager. Tartaglia, eight days before the ſtipulated time, diſcovered not only the mode of reſolving the caſe of Florido, viz. $x^3 + bx = c$, but alſo the caſe $x^3 = bx + c$. On the day of meeting, Tartaglia reſolved all his adverſary's queſtions in the ſpace of two hours, without receiving one anſwer from Florido in return. Accordingly, the wager was decided in his favour, and he generouſly remitted the forfeit incurred by Florido. Cardan, who was preparing a large work in arithmetic, algebra, and geometry, having heard of Tartaglia's diſcoveries in cubic equations, was very anxious for obtaining his rules of ſolution, that he might inſert them in his propoſed work. After ſeveral urgent invitations, he at length prevailed on Tartaglia to pay him a viſit at Milan in the year 1539 ; and in a conference, induced this mathematician to furniſh him with his rule, which he did in 27 rude Italian verſes : but he firſt exacted from Cardan a promiſe on oath that he would not publiſh what he diſcloſed to him. Some difficulty afterwards occurring in the explication of theſe verſes, and in the uſe of the rule conveyed by them, Cardan obtained from Tartaglia the ſolution he requeſted. For ſome time Cardan kept his promiſe, though not without ſome ſuſpicions on the part of Tartaglia, with regard to his integrity. At length, however, when in 1545 he publiſhed his work entitled “Ars magna,” he inſerted in it the ſolution of Tartaglia, attributing it to the inventor. Tartaglia complained of Cardan's violation of faith ; and he juſtified himſelf by ſaying, that the additions which he had made to Tartaglia's method of ſolution, gave him a right to publiſh it. To this purpoſe Montucla obſerves, that Cardan had in fact the merit of partly extending, and much illuſtrating the theory of Tartaglia. The diſpute between them was long and acrimonious, and terminated only with the life of Tartaglia in 1557. The rules which occaſioned this conteſt, have, however, retained the name of Cardan : although it would be more equitable to give them the title of the formula of Tartaglia, ſince they were originally his. For a further account of this controverſy, and of the letters that paſſed between the diſputants, we refer to Montucla's Hiſt. Mathem. tom. i. p. 591, &c. and Hutton's Math. Dict. art. Algebra.

The philoſophical notions of Cardan, both as they reſpect matter and mind, are principally detailed in his works “De Subtilitate,” and “De Varietate Rerum ;” but they are ſo blended with fanatical viſions, and the moſt extravagant and delirious effuſions of myſtical folly, and ſo ill digeſted and arranged, that they cannot be eaſily explained or underſtood. They form a kind of confuſed medley, diſtinguiſhed more by an affectation of novelty and ſingularity, and by the indulgence of an unbridled imagination, than by a ſound and diſcriminating judgment ; and for want of methodical arrangement, they contribute little to the promotion of important and uſeful ſcience. They are, however, occaſionally intermixed with experiments and obſervations on natural phenomena ; and they are chiefly uſeful as by the freedom and boldneſs with which the author divulged them, they ſerve to emancipate the human mind from the fetters of ancient authority. Upon the whole, Cardan, notwithſtanding the variety and apparent originality of his writings, muſt be ranked among the unſucceſsful adventurers in philoſophy. Of his peculiar dogmas, the following may ſerve as a ſpecimen. “Primary matter, which remains immutably the ſame, fills every place, whence, without the annihilation of matter, there can be no vacuum. Three principles ſubſiſt every where ; matter, form, and mind. There are in matter three kinds of motion ; the firſt, from form to element ; the ſecond, the reverſe of this ; the third, the deſcent of heavy bodies. The elements, or paſſive principles are three ; water, earth, and air ; for naturally all things are cold, that is, deſtitute of heat. The agent in nature is celeſtial heat; the air, being expoſed to the action of the ſolar rays, is perpetually in motion. The moon, and all the other heavenly bodies, are luminous from themſelves. The heavens are animated by an ever active principle, and are therefore never quieſcent. Man, having mind as well as ſoul, is not an animal. The diſpoſitions of men are produced, and all moral affairs are directed by the influence of the ſtars. The mind is univerſally diffuſed, and though it appears multiplied, is but one; it is extrinſically, and for a time, attached to human bodies, but never periſhes."

In his book above-mentioned, "De Subtilitate," Cardan compares the dogmas of various religions, and the arguments for them, and it is ſaid, puts the weaker in the mouth of the Chriſtian. The works of Cardan, treating of metaphyſics, logic, natural philoſophy, medicine, mathematics, and morals, were collected by Spon, and publiſhed in ten volumes folio, Leyd. 1663. Of his numerous and multifarious publications, one reaſon is aſſigned from his own confeſſion, that his poverty induced him to fill up his ſheets, with which he ſupplied his bookſeller at a fixed price, with any thing that occurred to him. To this circumſtance ſome have aſcribed the various diſcuſſions and conſequent obſcurity that have puzzled his readers. He was attacked with much acrimony by ſeveral writers, and particularly by J. C. Scaliger, who is ſaid to have envied his philoſophical reputation and medical ſucceſs. Brucker's Hiſt. Phil. by Enfield, vol. ii. p. 518. Gen. Dict. Moſheim E. H. vol. iv. p. 163. Haller's Bib. Med. pract. Chirurg. Anat. et Botan., et Eloy. Dict. Hiſtor.

CARDANO, in *Geography*, a town of Italy, in the duchy of Milan, ſeated on the Arno.

CARDASS, a ſort of card, proper for carding flocks of ſilk, to make cappadine of it. It is alſo the name which the French give to thoſe flocks of ſilk.

Cardasses is alſo the name which, in the cloth manufactories of Languedoc, they give to a ſort of large card, which is uſed for carding the dyed wool, deſigned for making cloth of mixed colours.

CARDAVA, in *Ancient Geography*, a town placed by Pliny in the interior of Arabia.

CARDEN, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and electorate of Treves, ſeated on the Moſelle; 27 miles N.E. of Treves.

CARDENNOSSA, a town of Spain, in Old Caſtile; 4 leagues from Avila.

CARDERS, in the *Woollen Manufactory*, are perſons who prepare wool, &c. for ſpinning, &c. See Carding and Cloth.

Carders, ſpinners, weavers, fullers, ſheermen, and dyers, not performing their duty in their occupations, ſhall yield to the party grieved, double damages; to be committed until payment. One juſtice to hear and determine complaints.

Carders, combers, ſorters, ſpinners, or weavers, conveying away, embezzling, or detaining any wool or yarn, delivered by the clothier, or any other perſon, ſhall give the party grieved ſuch ſatisfaction as two juſtices, mayor, &c. ſhall think fit: if not able or willing to make ſatisfaction, for the firſt offence to be whipped, or ſet in the ſtocks in ſome market-town, or in any other town where the offence is committed: the ſecond offence to incur the like, or ſuch further puniſhment, by whipping, &c. as juſtices ſhall think proper. Conviction by one witneſs on oath, or confeſſion.

CARDI, Ludovico, called *Cigoli* and *Civoli*, in *Biography*, an eminent hiſtorical painter, a ſcholar of Santi di Titi, gave a new ſtyle to the Florentine ſchool, and, though he did not approach nearer to the ſtyle of Correggio than any of his contemporaries, as Baldinucci expreſſes himſelf, he acquired very conſiderable eminence in his art. He availed himſelf with ſucceſs of Correggio's chiaroſcuro, joined to it ſkill in deſign which he acquired from the antique ſtatues, and from the works of Michael Angelo, Buonarotti, and other maſters in correct drawing, and ſet it off by judicious perſpective, and a much more lively colour than that of the Tuſcan ſchool; nevertheleſs, his pictures do not exhibit that contraſt of tints, that impaſto, that ſplendour, that graceful air, thoſe bold fore-ſhortenings, which conſtitute the character of the head of Lombard art. Whilſt the general tone of his colour is Lombardeſque, his draperies reſemble thoſe of Paolo Veroneſe, and he ſometimes approaches the depths of Guercino. To the claſs of his excellent pictures, poſſeſſed by the grand duke of the Pecori family, and diſperſed through private collections at Florence, we may refer his Trinity, in the church of St. Croce, his St. Albert, in that of St. Maria Maggiore, the Martyrdom of Stephen, at the Siſters of Monte Domini, which Pietro da Cortona ranked with the principal pictures at Florence. St. Anthony converting a Heretic is conſidered as ſuperior to any other at Cortona. His St. Peter healing the Cripple, in the Vatican at Rome, is placed by Andrea Sacchi next to the Transfiguration of Raphael and the St. Jerom of Domenichino. The merit of this picture, now indeed utterly deſtroyed by the humidity of the place, and other circumſtances, procured him the title of Cavaliere. This great artiſt alſo engraved a few plates in a ſlight, neat ſtyle, evincing, however, the hand of a maſter. Among others is a ſmall plate repreſenting "Mary Magdalen waſhing the Feet of Chriſt, at the Table of Simon the Phariſee." The heads of the figures, which are numerous, are remarkably beautiful; particularly thoſe of our Saviour and Mary Magdalen. He died at Rome in 1613, aged 54. Pilkington and Strutt.

CARDIA, in *Anatomy*. See Stomach.

Cardia, in *Ancient Geography*, a town ſituated near the Cherſoneſus of Thrace, at the bottom of a gulf, and to the weſt of the iſthmus, which joins the peninſula to Thrace, near the mouth of the Melas. It derived its name, according to Pliny, from its being built in the form of a heart. This city was conſiderable, when it was ſurrendered to the Athenians, at the time of the conteſt of the king of Thrace with Philip. They founded colonies in it, in order to ſecure the poſſeſſion of it, but afterwards abandoned it. Lyſimachus, the ſucceſſor of Alexander, demoliſhed it, and from its ruins raiſed the city of Lyſimachia, in the iſthmus of the Cherſoneſus. It probably recovered itſelf, as Ptolemy, five centuries after the reign of Lyſimachus, repreſents it as a town. There were medals of this city in ſilver, bronze, and gold, with the ſymbol of a heart.

CARDIAC, or Cordial *Medicines*, thoſe ſubſtances which, by their ſtimulant operation, excite an agreeable ſenſation of warmth in the ſtomach, and give it a temporary degree of tone. Hence they are alſo called *ſtomachic*. The ſenſation of warmth is produced partly by the peculiar impreſſion of theſe ſubſtances on the nervous coat of the ſtomach, and partly by the accelerated circulation in its veſſels, which neceſſarily occaſions a greater evolution of caloric. In conſequence of the general ſympathy of the different organs of the body with the ſtomach, this ſtimulant operation is communicated to the heart and arterial ſyſtem, and to the brain or common ſenſorium; whence the ſpirits are raiſed, a greater propenſity to motion and active thought is produced, and the general ſenſations of the whole frame are rendered more pleaſurable. That this extenſion of the effect takes place in conſequence of nervous ſympathy, and not by any actual communication of the cordial ſubſtance to the different parts by the veſſels, is evinced by the inſtantaneous manner in which it is effected. Farther than this, we know nothing of the mode in which this operation is accompliſhed; it can only be ſtated, as an ultimate fact, that ſuch a relation between the ſubſtances, which come under this denomination, and the living body, exiſts. No hypotheſis, ſuch as the older phyſicians adopted, of a chemical combination of the medicine with the fluids or ſolids of the body, or of a mechanical action of the one upon the other, renders the operation in the leaſt degree more intelligible.

Although the terms *Cardiac*, from the Greek, καρδια, and *Cordial*, from the Latin *Cor*, (both ſignifying *the heart*,) imply the ſame thing; yet a diſtinction ſeems to be generally made at preſent in their application: the term *cardiac* being confined more particularly to aromatic ſubſtances, and *cordial* being uſed, as including eſſential oils, vinous and ſpirituous liquors, and other diffuſible ſtimulants.

The operation of aromatic ſubſtances and eſſential oils is conſiderably different from that of vinous and ſpirituous liquors. The ſtimulus of the former is more confined to the ſtomach; they do not affect the ſenſorium, ſo as to produce intoxication; they leave a leſs uneaſy ſenſation, when their operation ceaſes, and therefore produce leſs neceſſity for a repetition; and they are much leſs pernicious to the conſtitution, as they do not ſeem, when taken in exceſs, to occaſion thoſe morbid derangements of the viſcera, (eſpecially of the liver,) which are among the moſt common and fatal conſequences of the abuſe of wine and ſpirits.

Cordials, in moderate quantities, are beneficial in debilitated habits, eſpecially where the digeſtive powers are weak. They give a temporary ſtrength to the ſyſtem; and, by their ſtimulus to the ſecretory veſſels of the ſtomach, they increaſe the ſecretion of the gaſtric fluid, and thus, by promoting the formation of a nutritious chyle, tend to add a permanent ſtrength to the body.

In the treatment of particular diſeaſes, they may be advantageouſly combined with the more permanent tonics, as in hyſteria, chloroſis, epilepſy, and ſome others, in which great nervous mobility prevails; with diuretics, in the dropſies of old people and of debilitated conſtitutions; and with narcotic medicines, ſuch as digitalis, cicuta, &c. which are liable to excite nauſea, or otherwiſe to diſagree with the ſtomach. In the laſt ſtages of putrid diſeaſes, as they are commonly called, ſuch as typhous fever, putrid ſore-throat, confluent ſmall-pox, &c. they are of incalculable utility, (particularly wine,) and afford the laſt reſources for ſupporting the ſinking powers of life, and for ſuſtaining that force and regularity of circulation, which is neceſſary to the performance of the functions.

**Cardiac** *orifice*, of the ſtomach, in *Anatomy*, is the opening by which the œſophagus communicates with that receptacle. It is called alſo the œſophageal, the ſuperior, or the left opening of the ſtomach. See Stomach.

**Cardiac** *opening* of the diaphragm, is the ſuperior of the two openings formed between the appendices or crura diaphragmatis, and tranſmits the œſophagus, together with the right and left nerves of the eighth pair, or par vagum. See Diaphragm.

**CARDIACA**, in *Botany*, Hall. Helv. n. 274. See Galeobdolon.

**Cardiaca**, Hall. Helv. n. 275. See Stachys *ſylvatica*.

**Cardiaca**, Amm. Ruth. 49, 50. Mil. Icon. 80. See Leonurus *tataricus*.

**Cardiaca**, ſive Leonurus. Pluk. Alm. 81. tab. 118. *fig.* 4. See Phlomis *zeylanica*.

**Cardiaca**, Herm. Lugd. 115. tab. 117. See Phlomis *repetifolia*.

**CARDIACUS** *Plexus*, in *Anatomy*, is formed by the nerves which ſupply the heart, and which are derived from the ſuperior and inferior cervical, and firſt dorſal ganglia of the great ſympathetic nerve, from the par vagum and the recurrent nerve. See Heart and Nerves.

**CARDIALGIA**, in *Medicine*, a term formerly uſed in a more general ſenſe to deſignate any pain or uneaſineſs about the region of the ſtomach, eſpecially if connected with a tendency to ſyncope (Sauvages Noſol. Meth. cl. vii. ord. 4.); but at preſent confined to that painful ſenſation of heat and acrimony about the ſuperior orifice of the ſtomach, which, from the vicinity of its ſeat to the heart, is popularly called *heart-burn*. The term is from καρδια, which ſignifies both the *heart*, and upper orifice of the ſtomach, and αλγος, *pain*.

This painful ſenſation is produced by the irritation of an *acid* matter in the ſtomach, which riſes to the upper orifice, ſometimes by eructation into the œſophagus and throat, and is ſometimes completely ejected by vomiting. That this irritating matter is of an acid nature, is evinced by the taſte; and it has even been ſeen to produce an effervеſcence on falling on a marble hearth, according to Dr. Darwin, (Zoonomia, claſs I. 2, 4, 5.). When vomited, or raiſed by eructation, it is ſometimes ſo intenſely ſour, as to abrade the mouth and throat; and, in general, it produces a ſenſation in theſe parts ſimilar to that which exiſts in the ſtomach.

The production of the acid is thus accounted for. It has been aſcertained by the experiments of Spallanzani and others, that the proceſs of digeſtion is effected by means of the ſolvent powers of the gaſtric juice; and that, during health, while it is perfectly performed, no degree of fermentation occurs. But when, from a deficiency of the ſolvent fluid, or ſome morbid change in its qualities, digeſtion is delayed or imperfectly accompliſhed, the natural chemical changes, which a maſs of animal and vegetable matter is diſpoſed to undergo, enſue, fermentation takes place, and an acid is conſequently evolved. It is obvious, therefore, that cardialgia is not to be conſidered as a diſtinct ſpecies of diſeaſe, but as one of the ſymptoms of indigeſtion, or of the weakneſs or inactivity of the ſtomach; and it is produced by all the cauſes of indigeſtion. See Dyspepsia. Particular kinds of food, however, are liable to produce cardialgia, in thoſe who are pre-diſpoſed to indigeſtion, rather than the other ſymptoms which often attend it; ſuch are hot new bread, eſpecially of the coarſer kinds, rich paſtry, &c. It is a very common ſymptom of that morbid condition of the ſtomach, which exiſts in the early and laſt ſtages of pregnancy.

The complaint may be palliated by mucilaginous matters, ſuch as Spaniſh liquorice, or gum Arabic, which ſheath the irritated parts, and, by ſupplying the deficiency of mucus, preſerve the ſenſible membranous lining of the ſtomach from the acrimonious fluid.

It may be certainly relieved, and, if ſlight, may be effectually cured, by the uſe of ſuch medicines as may combine with, and neutralize the acid, from which it originates. For this purpoſe the vegetable or foſſil alkalies may be employed in various forms; the ſoda-water, as a common drink, is a convenient form: the abſorbent earths, as magneſia, chalk, &c. will anſwer a ſimilar end. But where the complaint is ſevere, or of ſome ſtanding, the only effectual method of cure conſiſts in removing that ſtate of debility of the ſtomach on which the indigeſtion depends. This muſt be effected by temperance and exerciſe, with the aſſiſtance of tonic and ſtimulant medicines, ſuch as ſteel, colombo, and other bitters, with a moderate portion of wine and aromatics. Care ſhould be taken not to charge the ſtomach with a larger quantity of food than it can readily digeſt, ſince the overplus will neceſſarily tend to fermentation.

Dr. Darwin remarks, that as the ſaliva, ſwallowed along with our food, prevents its fermentation, according to the experiments of Pringle and Macbride, conſiderable relief is ſometimes found by chewing parched wheat or maſtic, or a lock of wool, frequently in a day, when the pain occurs, and by ſwallowing the ſaliva thus effuſed.

CARDIFF, or CAERDYFF, in *Geography*, the county-town of Glamorganſhire, South Wales, derives its name from its ſituation on the river Taf, which runs along the weſt ſide of it, and falls into the Severn, three miles below the town. It conſiſts of ſeveral ſpacious ſtreets of well-built houſes, and is pleaſantly ſituated on a fertile flat, two miles and a quarter from the eaſtern extremity of the county, where it is joined by Monmouthſhire. The town was formerly ſurrounded with walls flanked with watch-towers, 1280 paces in circumference, and had gates at the four cardinal points, ſome traces of which are ſtill viſible. Cardiff conſiſts of two pariſhes, St. John's and St. Mary's, though there is at preſent but one church: for the church of St. Mary was, in 1607, undermined and thrown down by the inundations of the river, which ſtill occaſionally repeats its depredations. The high tower of the preſent church was built, it is ſaid, at the latter end of the reign of Edward III. It is of light appearance, and of elegant workmanſhip: having open corners and lantern pinnacles. Here were formerly four religious houſes: a benedictine priory, and houſes of black, grey, and white friars. Thoſe of black and white friars were founded by Robert earl of Glouceſter, and continued, till the diſſolution, under Henry VIII. A few remains of the white friars are ſtill to be ſeen; and the ruins of the black friars are near the eaſtern wall and gate-way, and furniſh habitations for a few poor fiſhermen. The chief object of attention is the ancient caſtle, which is a large, ſtately edifice, on the north ſide of the town wall. It was originally of great ſtrength, and is ſaid to have covered eight acres of ground. It was built by the conqueror Fitzhamon, in 1090, after he had poſſeſſed himſelf of the country of Morgannoc. The entrance is by a bold gate-way, furniſhed with two portculliſſes and maſſy gates. The ruins of the caſtle have been repaired and modernized under the preſent poſſeſſor, the marquis of Bute. On the keep, which ſtands in the centre of the incloſed area, is a handſome octangular tower; and a high terrace is carried round the inſide of the whole extent of the embattled walls that ſurround it. This caſtle, ſituated in the midſt of the Anglo-Norman territory, experienced but few of thoſe incidents ſo common to many others. It is memorable as the ſcene of the unjuſt impriſonment and death of Robert duke of Normandy, by his brother Henry I. In May 1645, it was garriſoned by the Welſh loyaliſts for the king; but in Auguſt the following year, after ſuſtaining a ſhort ſiege, ſurrendered to the parliamentary forces. The inhabitants of Cardiff and its vicinity carry on a conſiderable trade to Briſtol, and ſend thither great quantities of oats, barley, ſalt butter, and poultry of all kinds. The iron-works of the adjacent country have greatly added to the conſequence of this town, nearly 9000 tons of caſt and wrought iron being exported annually for London and other places. By an act which paſſed in 1790, a canal was cut from Penarth Point to the Cyfartha iron-works, near Merthyr Tidvil; which has greatly facilitated the conveyance of ſo ponderous an article of commerce to market: this canal was brought, with great ingenuity, through a mountainous country, to the extent of twenty-five miles; its head, at Merthyr Tidvil, is 568 feet higher than the tide lock at Cardiff. By a ſubſequent act a branch has been extended to other works at Aberdare, while the diviſion of the line below the town has been widened and depened, ſo as to admit brigs and other veſſels of 300 tons burthen up to the quay. See *Glamorganſhire* CANAL. The aſſizes are regularly held at Cardiff; and the beauty of the neighbourhood is ſometimes diſplayed at its concerts and aſſemblies. By the late return the population of this town is 1870, and the number of houſes 327. It is 160 miles W. from London, and has two weekly markets on Wedneſdays and Saturdays.

About three leagues ſouth of Cardiff are two iſlands, called the Flat and Steep Holmes; on the former of which there is a light-houſe, and a good dwelling, where pilots frequently wait to conduct ſhips up the Briſtol channel: this iſland contains ſixty acres of land, and is well cultivated. A little to the weſt of theſe iſlands is a ſmall one called Sully; and three miles weſtward of that is another named Barry, from St. Baruch, who is ſaid to have been interred there. Evans's Tour through South Wales, 8vo. 1804. Malkin's Scenery, Antiquities, &c. of South Wales, 4to. 1804.

CARDIGAN, in Welſh *Aberteivi*, is the county-town of Cardiganſhire, in South Wales. The houſes ſtand on the declivity of a hill, at the bottom of which runs the river Teifi or Tivy, which has at its mouth a dangerous bar. This is navigable at high tides for brigs of 150 tons burthen, which are laden and unladen at the quay. Previous to the war here was a conſiderable export trade to Ireland, &c. in lead and corn; but the iron works in the vicinity furniſh it, at preſent, with its chief commerce. About two miles from the town the river diſcharges itſelf into Cardigan-bay. A bridge of ſeven arches croſſes the river, and near it ſtands the ſhell of a caſtle, which is ſaid by many writers to have been built by Gilbert de Clare, who alſo fortified the town, in the time of Henry II. Powel, however, in his "Hiſtory of Wales," aſſerts, that a caſtle was built here, in 1155, for the defence of the borders. This was beſieged by Rhys Gryffydd, in 1164, when it was taken, and razed to the ground. In 1176, Cardigan was a ſcene of peculiar public feſtivity, when numbers of Engliſh, Welſh, Iriſh, and Normans, aſſembled to celebrate a grand eiſteddfod. The bards and minſtrels of the principality diſplayed pre-eminent ſkill on this occaſion. They, conſequently, record the approbation and thanks of the aſſembly; and, being victors, were rewarded with honorary preſents. In the poetical claſs, the bards of North Wales were declared the moſt eminent; and, in muſic, the minſtrels of South Wales proved themſelves the conquerors.

On the banks of the river ſtands the church, a large handſome ſtructure; and near it are the ruins of a priory of black canons. In 1797, a new county-gaol was erected in this town. Cardigan is noted as the place where Gyraldus preached, and ſtrongly recommended the cruſade to the ancient Britons. Though the county-town, Cardigan has but little to recommend it to the attention of the hiſtorian or antiquary. Its houſes and ſhops are upon a very ſmall ſcale, and its local trade is but very inconſiderable. In conjunction with the outlying boroughs of Aberyſtwith, Lampeter, and Adpar, this town ſends one member to parliament. The number of voters amounts to about 1200. Cardigan gives the title of earl to the family of Brudenel. Here are a weekly market on Tueſdays, and four fairs yearly. Evans's Tour through South Wales, 8vo. 1804. Malkin's Scenery, Antiquities, &c. of South Wales, 4to. 1804.

Cardigan, a name once given to the townſhip Orange, in America, about 20 miles E. of Dartmouth college, in New Hampſhire. See Orange.

Cardigan *bay*, a bay of the Atlantic, on the weſt coaſt of Wales, W. and N.W. of the town of Cardigan. This bay is very extenſive, and is bounded by the coaſt of Pembroke which forms one horn of it, and by the extreme point of Caernarvonſhire terminating in the iſle of Bardſea, which forms the other.

CARDIGANSHIRE, a county of South Wales, is a long narrow diſtrict bordered to the weſt by that part of St. George's channel, called Cardigan-bay. On this coaſt the ſea has made great encroachments, and according to the tradition of the country, a large tract of land, well inhabited, has been ſwept away by the waves. This coaſt is particularly animadverted on by ſome of the ancient Welſh bards. The other boundaries of the county are, Merionethſhire and Montgomeryſhire on the north, Radnorſhire and Brecknockſhire on the eaſt, and Caermarthenſhire and Pembrokeſhire on the ſouth. The area meaſures about 40 miles in length, by 20 in breadth. This diſtrict is divided into five hundreds; and contains ſix market-towns, and 64 pariſhes, which are included in the dioceſe of St. David's. Cardiganſhire may be properly divided into two diſtricts, and characterized by the lower, and the upland. The higher grounds of the former conſiſt of a light ſandy loam, varying in depth from twelve to four and five inches; the ſubſtratum is a ſlaty kind of rock. The ſoil of the upland diſtrict is extremely ſhallow, and in general very barren. Indeed this mountainous region is naturally uncongenial to the purſuits of agriculture; yet the genius and induſtry of men might effect much, particularly by judicious plantations. This is laudably exemplified in the grounds at and about Hafod, where the patriotic proprietor, Thomas Johnes eſq., has rendered fertile and uſeful many thouſand acres of land. The ſcenery of Hafod, the Devil's bridge, and their vicinities, is ſingularly grand, pictureſque, and romantic. This northern part of the country abounds with deep narrow chaſms between the mountains, through which the waters often ruſh with great impetuoſity; and particularly after ſtorms, or continued rains, when they form immenſe torrents, and in many places are precipitated in roaring caſcades. "The whole of this rugged region," obſerves Mr. Malkin, "is one immenſe reſervoir of metallic treaſure, awaiting only the ſpirit of enterpriſe, and the hand of induſtry to draw it into light and uſe;" but the purſuits of agriculture have hitherto ſuperſeded thoſe of commerce. The principal rivers of this county are the Rydol, the Yſtwith, and the Clewedog. Malkin's Scenery, Antiquities, &c. of South Wales, 4to. 1804.

CARDINAL, a term ſerving to expreſs the relation, or quality of prime, principal, or moſt conſiderable. The word is formed of the Latin *cardo, a hinge;* it being on theſe fundamental points that all the reſt of the ſame kind are ſuppoſed to turn. Thus, juſtice, prudence, temperance, and fortitude, are called the four *cardinal virtues*, as being the baſis of all the reſt.

Cardinal *flower*. See Lobelia Dortmanni.

Cardinal *Points*, in *Coſmography*, are the four interſections of the horizon with the meridian and the prime vertical circle. Of theſe, two, viz. the interſections of the horizon and meridian, are called *North* and *South*, with regard to the poles they are directed to.

To determine the places of theſe points, ſee Meridian *line*.

The other two, viz. the interſections of the horizon and firſt vertical, are called *Eaſt* and *Weſt*.

The cardinal points, therefore, coincide with the four cardinal regions of the heavens; and are 90° diſtant from each other. The intermediate points are called collateral points.

Cardinal *Points of the Heavens*, or, *of a Nativity*, in *Aſtrology*, are the riſing and ſetting of the ſun, the zenith and nadir.

Cardinal *Signs*, in *Aſtronomy*, are Aries, Libra, Cancer, and Capricorn. See Sign.

Cardinal *Winds* are thoſe that blow from the cardinal points.

Cardinal *Numbers*, in *Grammar*, are the numbers one, two, three, &c. which are indeclinable; in oppoſition to the ordinal numbers, firſt, ſecond, third, fourth, &c. See Number.

Cardinal is more particularly uſed for an eccleſiaſtic prince, one who has a voice, both active and paſſive, in the Roman conclave, at the election of a pope.

Some ſay, the cardinals were ſo called from the Latin *incardinatio*, which ſignifies the adoption in any church made of a prieſt of a foreign church, driven thence by misfortune; and add, that the uſe of the word commenced at Rome and Ravenna; the revenues of the churches of which cities being very great, they became the common refuge of the unhappy prieſts of all other churches.

The cardinals compoſe the pope's council, or ſenate: in the Vatican is a conſtitution of pope John, which regulates the rites and titles of the cardinals; and which declares, that as the pope repreſents Moſes, ſo the cardinals repreſent the ſeventy elders, who under the pontifical authority decide private and particular differences.

Cardinals, in their firſt inſtitution, were only the principal prieſts, or incumbents of the pariſhes of Rome. In the primitive church, the chief prieſt of a pariſh, who immediately followed the biſhop, was called *preſbyter cardinalis;* to diſtinguiſh him from the other petty prieſts, who had no church, nor preferment; the term was firſt applied to them in the year 150; others ſay, under pope Silveſter, in the year 300. Theſe cardinal prieſts were alone allowed to baptize, and adminiſter the euchariſt. When the cardinal prieſts became biſhops, their cardinalate was vacated; they being then ſuppoſed to be raiſed to a higher dignity.—Under pope Gregory, cardinal prieſts, and cardinal deacons, were only ſuch prieſts or deacons as had a church or chapel under their particular care: and this was the original uſe of the word. Leo IV. in the council of Rome, held in 853, calls them *preſbyteros ſui cardinis;* and their churches *parochias cardinales*.

The cardinals continued on this footing till the eleventh century; but as the grandeur and ſtate of his holineſs became then exceedingly augmented, he would have his council of cardinals make a better figure than the ancient prieſts had done. It is true, they ſtill preſerved their ancient title; but the thing expreſſed by it was no more. It was a good while, however, before they had the precedence over biſhops, or got the election of the pope into their hands: but when they were once poſſeſſed of thoſe privileges, they ſoon had the red hat and purple; and growing ſtill in authority, they became at length ſuperior to the biſhops, by the ſole quality of being cardinals.

Du-Cange obſerves, that originally there were three kinds of churches: the firſt or genuine churches were properly called *pariſhes*; the ſecond, *deaconries*, which were chapels joined to hoſpitals, and ſerved by deacons; the third were ſimple *oratories*, where private maſſes were ſaid, and were diſcharged by local and reſident chaplains. He adds, that to diſtinguiſh the principal, or pariſh churches, from the chapels and oratories, the name cardinals was given them. Accordingly, pariſh churches gave titles to cardinal prieſts; and ſome chapels alſo, at length, gave the title of cardinal deacons.

Others obſerve, that the term cardinal was given not only to prieſts, but alſo to biſhops and deacons who were attached to certain churches; to diſtinguiſh them from thoſe who only ſerved them *en paſſant*, and by commiſſion. Titular churches, or benefices, were a kind of pariſhes, i. e. churches aſſigned each to a cardinal prieſt; with ſome ſtated diſtrict depending on it, and a font for adminiſtering of baptiſm, in caſes where the biſhop himſelf could not adminiſter it.—Theſe cardinals were ſubordinate to the biſhops; and, accordingly, in councils, particularly that held at Rome in 868, ſubſcribed after them. It was not, however, only at Rome, that prieſts bore this name; for we find there were cardinal prieſts in France; thus, the curate of the pariſh of St. John de Vignes is called, in old charters, the cardinal prieſt of that pariſh.

The title of cardinal is alſo given to ſome biſhops, *quatenus* biſhops; e. g. to thoſe of Mentz and Milan: the archbiſhop of Bourges is alſo, in ancient writings, called cardinal; and the church of Bourges a cardinal church. The abbot of Vendome calls himſelf *cardinalis natus*.

The cardinals are divided into three claſſes, or orders; containing ſix biſhops, 50 prieſts, and 14 deacons; making in all, 70: which conſtitute what they call the *ſacred college*. The cardinal biſhops, who are as it were the pope's vicars, bear the titles of the biſhopricks aſſigned to them; the reſt take ſuch titles as are given them; the number of cardinal biſhops has been fixed; but that of cardinal prieſts and deacons, and conſequently the ſacred college itſelf, is always fluctuating. Till the year 1125, the college only conſiſted of 52, or 53: the council of Conſtance reduced them to 24; but Sixtus IV. without any regard to that reſtriction, raiſed them again to 53, and Leo to 65. Thus, as the number of cardinal prieſts was anciently fixed to 28, new titles were to be eſtabliſhed, in proportion as new cardinals were created.—As for the cardinal deacons, they were originally no more than ſeven, for the 14 quarters of Rome; but they were afterwards increaſed to 19, and after that were again diminiſhed. It has been ſaid, however, (ſee Moſheim, E. H. vol. ii. p. 485.) that cardinal deacons were not from the beginning members of that ſacred college, by whom the popes were elected. Although there were in the Roman church long before the edict of Nicholas (mentioned below), and there ſtill remain, cardinal deacons, i. e. ſuperintendants of thoſe churches which have hoſpitals annexed to them, and whoſe revenues are appropriated to the ſupport of the poor; yet they were evidently excluded from the election of the pope, which, by the edict of Nicholas, was to be made by the cardinal biſhops and clerks alone. Accordingly we find the cardinals plainly diſtinguiſhed from the deacons in the diploma that was drawn up for the election of Gegory VII. to the pontificate.

According to Onuphrius, it was pope Pius IV. who firſt enacted, in 1562, that the pope ſhould be choſen only by the ſenate of cardinals: whereas, till that time, the election was by all the clergy of Rome. Some ſay, the election of the pope reſted in the cardinals, excluſive of the clergy, in the time of Alexander III. in 1160. And they allege, that, in order to avoid the uſual contentions and diſturbances at the election of a pope, he made a decree in the third Lateran council, A. D. 1179, that for the future the right of chuſing him ſhould be veſted in the cardinals only, and that he ſhould be a lawful pope who had the ſuffrages of two-thirds of the college of cardinals; which law is ſtill in force. See ALEXANDER. Others go higher ſtill, and ſay, that Nicholas II. having been elected at Sienna, in 1058, by the cardinals alone, occaſioned the right of election to be taken from the clergy, and people of Rome; only leaving them that of confirming him by their conſent; which was at length, however, taken from them. See his decree for this purpoſe, iſſued in the Roman council of 1059, in Hardouin's Acta Conciliorum, tom. vi. pt. i. p. 1165. "We have thought proper to enact," ſays the pontiff, "that, upon the deceaſe of the biſhop of the Roman catholic or univerſal church, the affair of the election be treated principally, and previouſly to all other deliberations, among the *cardinal biſhops* alone, who ſhall afterwards call in to their council the *cardinal clerks*, and require finally the conſent of the reſt of the clergy and the people to their election." Whence it appears, that the cardinals who had the right of ſuffrage in the election of his ſucceſſors, were divided by this pontiff into cardinal biſhops and cardinal clerks: meaning by the former the ſeven biſhops who belonged to the city and territory of Rome, and to whom it belonged to conſecrate the Roman pontiff; and by the latter, the cardinal preſbyters or miniſters of the 28 Roman pariſhes, or principal churches. To theſe were added, in proceſs of time, under Alexander III. and other pontiffs, new members, in order to appeaſe the tumults occaſioned by the edict of Nicholas II. Accordingly Alexander completed what Nicholas had only begun, by transferring and confining to the college of cardinals the right of electing to the apoſtolic ſee, and excluding the nobility, the people, and the reſt of the clergy from all concern in this important matter. In order to defeat the oppoſition of the higher order of clergy, he augmented the college of the electing cardinals by conferring that dignity upon the prior, or arch-preſbyter of St. John Lateran, the arch-preſbyters of St. Peter's and St. Mary Maggiore, the abbots of St. Paul's and St. Laurence without the wall, and, laſtly, upon the ſeven Palatine judges. And the inferior clergy were reduced to ſilence by the promotion of their chiefs, the *cardinal deacons*, to the dignity of electors. Who it was, whether Alexander III. or ſome other pontiff, that raiſed the principal Roman deacons to the rank of cardinals, is not certain; but it is very evident, that the deſign of this promotion was to put an end to the murmurs and complaints of the inferior clergy, who reſented highly the violation of their privileges.

We may conclude, upon the whole, that the college of cardinals, and the extenſive authority, and the important privileges enjoyed by them at this day, derive their origin from the edict publiſhed at the requeſt and under the pontificate of Nicholas II.; that, under the title of cardinals, this pontiff comprehended the ſeven Roman biſhops, who were conſidered as his ſuffragans, and of whom the biſhop of Oſtia was the chief, as alſo the 28 miniſters, who had inſpection over the principal Roman churches; and that to theſe were added, in proceſs of time, under Alexander III. and other pontiffs, new members, in order to appeaſe the reſentment of thoſe who looked upon themſelves as injured by the edict of Nicholas, and alſo to anſwer other purpoſes of eccleſiaſtical policy. It is alſo unqueſtionable, that, though the higher order of purpled prelates, commonly called cardinals, had its riſe in the 11th century, yet it does not

not ſeem to have acquired the ſtable and undiſputed authority of a legal council before the following age and the pontificate of Alexander III. See Conclave.

The cardinals obtained the privilege of wearing the red hat as an emblem of their readineſs to ſhed their blood for the catholic faith, in conſequence of the grant made to them by Innocent IV. at the council of Lyons, in 1245; but they are ſaid to have firſt uſed it in the year after the council, i. e. in 1246, on occaſion of an interview between the pope and Lewis IX. of France. That the cardinals were allowed to wear red ſhoes and red garments in the time of Innocent III. raiſed to the ſee in 1198, appears from ſeveral writers who flouriſhed at that time; but it is not certain which of the popes conferred upon them that diſtinction. Paul II. elected to the papacy in 1464, added the red cap and ſcarlet houſings for capariſoning their horſes when they rode. The decree of pope Urban VIII. whereby it is appointed, that the cardinals be addreſſed under the title of *eminence*, is of the year 1630; till then, they were called *illuſtriſſimi*.

See further concerning the origin and rights of cardinals in Onuphrius, Duarenus, Ciaconus. Aubery has given the general hiſtory of cardinals, in five volumes, 4to.

Cardinal has alſo been applied to ſecular officers.

Thus, the prime miniſters in the court of the emperor Theodoſius, are called *cardinales*. Caſſiodorus, lib. vii. Formul. 31. makes mention of the cardinal prince of the city of Rome; and in the liſt of officers of the duke of Bretagne, in 1447, we meet with one Raoul de Thorel, cardinal of Quillart, chancellor, and ſervant of the viſcount de Rohan: which ſhews it to have been an inferior quality.

Cardinal's *iſland*, in *Geography*, a ſmall iſland near the eaſt coaſt of Labrador. N. lat. 59° 30′. W. long. 63° 50′.

Cardinal *bird*, in *Ornithology*, ſynonymous with *Cardinalitius* and *Loxia cardinalis*.

CARDINALIS *capitis bonæ ſpei*, Briſſ. and Cardinal *du cap de bonne eſpèrance*, Buff. See Loxia *orix*, the grenadier of Engliſh writers. *Le cardinal* of Buffon is another bird, the Gmelinian Tanagra *braſilia*, which ſee. *Cardinalis purpureus* of Briſſ. is the *Jacapu* of Marcgrave, *Tanagra jacapa* of Gmelin. *Cardinalis* is alſo the ſpecific name of ſeveral birds in the Linnæan ſyſtem, as will be noticed in their reſpective genera.

CARDINALITIUS, a name given by ſome to the Virginian nightingale, Loxia *cardinalis*, which ſee.

CARDING, in the *Manufactories*, a preparation of wool, cotton, hair, or flax, by paſſing it between the iron points, or teeth, of two inſtruments, called *cards*, to comb, diſentangle, and range the hairs or fibres thereof; and to diſpoſe it for ſpinning, &c. See Cards.

Before the wool be carded, it is oiled, or greaſed with oil; whereof, one-fourth of the weight of the wool is required, for wool deſtined for the woof of ſtuffs; and one-eighth for that of the warp. See Cloth.

CARDIOGMUS, or Cardionchus, (compounded of καρδία, *the heart*, and ὄγκος, *tumour*) in *Medicine*, a dilatation of one or all the cavities of the heart. The term includes two ſpecies of diſeaſe; viz. a partial enlargement of the heart, forming a ſac, in which coagulable lymph is depoſited, and which is uſually denominated aneuryſm of the heart; and that more common diſeaſe, which conſiſts ſimply in a general dilatation of the natural cavities.

The ſymptoms which belong to aneuryſm of the heart are the ſame as thoſe which accompany aneuryſm of the arch of the aorta. (Baillie Morb. Anat. p. 42.) See Aneurysm.

When the heart, or any of its cavities, is much enlarged, it is attended with ſevere palpitations, which are excited by the leaſt motion or exertion, and often increaſe to the moſt violent and diſtreſſing paroxyſms; ſo that they may not only be felt by the hand, when applied to the left ſide, but at the pit of the ſtomach, and at the top of the ſternum; and they may frequently be perceived by the eye through the ordinary clothing, and occaſionally, it is ſaid, may even be heard. The other ſymptoms are, a ſenſe of weight, and a conſtant anxiety about the cheſt; ſometimes accompanied with a violent pain acroſs the breaſt, in the abdomen, or the back; and ſometimes with fainting. There is frequently great difficulty of breathing, with a ſenſe of ſuffocation, which compels the patient to ſit in the erect poſture, or to ſeek repoſe by leaning on his breaſt. A purpliſh hue of the cheeks and lips, which varies at times, according to the degree of difficulty with which the blood is tranſmitted through the lungs; œdema of the face, or other dropſical ſwellings; flatulence of the ſtomach; and a haraſſing cough, are occaſional ſymptoms of the complaint. The pulſe is various in different inſtances; ſometimes it is feeble, ſmall, and intermitting; ſometimes extremely quick and hard; and ſometimes not ſynchronous with the contractions of the heart. When the palpitation is violent, the head is often affected with ſtrong diſtreſſing pulſations, which are ſometimes more complained of than thoſe of the heart itſelf.

The *diagnoſis* of this affection of the heart is of conſiderable importance; becauſe the moſt dreadful palpitations occaſionally ariſe from morbid irritability, independent of organic diſeaſe; and the treatment muſt neceſſarily be very different in the two inſtances. The enlargement of the heart is generally perceptible to the hand; its ſtroke is leſs pointed, or more obtuſe than natural, and is felt two or three ribs lower than in health. But, according to Dr. Ferriar, "the moſt certain ſign of dilatation is the jarring ſenſation given to the hand by each ſyſtole. The ſtroke ſeems reſtrained, and is ſucceeded by a kind of thrilling, which cannot be clearly deſcribed, but is entirely different from the ſhake of a palpitation." (Med. Hiſt. and Reflect. vol. i. p. 148.) Senac, with leſs diſcrimination, obſerves, that our principal guide, in determining the dilatation of the heart, muſt be the force of the palpitations, their continuance, and the facility with which they are excited, eſpecially if accompanied by ſyncope and dyſpnœa. (Traité du Cœur, tom. ii. chap. 8.) The ſymptoms, however, are ſometimes obſcure and treacherous.

It is more difficult, and of leſs importance, to determine which of the cavities of the heart is dilated. Where the auricles only are dilated, probably the pulſe will retain its ſtrength, as the ventricles poſſeſs their natural power; the palpitation will perhaps be leſs violent; and the enlargement leſs perceptible to the hand. (Senac.) And the dilatation may be conſidered as confined to the auricles, when the pulſation feels remote, and extending acroſs the breaſt, as well as downwards, and when the apex of the heart does not ſtrike the ribs very forcibly. (Ferriar.) M. Senac has farther obſerved, that when the right ventricle, or its auricle, is greatly dilated, the palpitations are comparatively trifling; the patients complain chiefly of a ſenſe of weight about the region of the heart; and there is alſo a pulſation in the veins of the neck.

In ſeveral inſtances there has been a great diſpoſition to gangrene in the extremities, which no medicine could counteract. This ariſes, no doubt, from the impaired force of the heart. For as its muſcular *parietes* are generally very thin, in proportion to the enlarged ſize of its cavities, the heart has little power to propel an increaſed quantity of blood into the more diſtant branches of the arterial ſyſtem. (Morb. Anat.)

In whatever cavity the dilatation exiſts, the diſeaſe is commonly fatal. The patients generally die ſuddenly, in ſyncope, or in a paroxyſm of palpitation ; ſometimes in conſequence of a rupture of the thin *parietes* of the dilated cavity ; but often without any ſuch rupture. The diſeaſe, however, is extremely irregular in its progreſs, and various in its duration. It will ſometimes appear to be ſtationary, or even retrograde, for a long interval, during which the ſenſations of the patient are tolerably comfortable, and he can uſe moderate exerciſe without inconvenience. At other times the paroxyſms are frequent, and he ſeems in perpetual danger of expiring. The duration of the complaint has been obſerved, in different inſtances, to vary from two or three months to nine years.

Various *cauſes* have been aſſigned for this diſeaſe. Senac enumerates in the liſt, all acute diſeaſes of the lungs, as well as aſthma and hydrothorax, fever, violent exerciſe, or turbulent paſſions, and exceſſive intemperance. According to Lanciſi, flute-players and preachers are ſubject to it ; and Dr. Pitcairn thinks that he has obſerved it to ariſe from a transferrence of rheumatiſm to the heart. Dr. Ferriar has ſeen it produced by raiſing great weights, or by too long a continuance of much bodily exertion ; and all the caſes which he has ſeen have been in *young* perſons. It is probable that any circumſtance which either acts as a ſtrong impediment to the free paſſage of the blood from the heart, or which excites a violent and long-continued afflux of blood to that organ, may, in ſome conſtitutions, where there is an original weakneſs of it, occaſion a dilatation.

Little can be ſaid as to the *cure* of dilatation of the heart ; for, except in the incipient ſtage, all that can be done is to ſoothe the diſtreſſing feelings of the patient, to render his exiſtence ſomewhat more comfortable, and thus perhaps to prolong its duration. With this view, much has often been done by medicine and proper management. The anxiety and palpitation may be alleviated by means of narcotic medicines, eſpecially by digitalis and opium, which diminiſh the irritability of the heart and arterial ſyſtem. The digitalis is ſometimes extremely uſeful in this complaint, and has appeared to ſuſpend its progreſs, and to produce long intervals of freedom from the diſtreſſing ſymptoms. Perhaps it may be ſerviceable partly as a narcotic, and partly as a diuretic ; ſince diuretics, whatever may be the explanation, give frequent relief in diſorders of the cheſt. All violent exerciſe, and great emotions of the mind, ſhould be avoided, ſince they tend to produce inordinate action of the heart. Moderation in diet ſhould be obſerved, and ſtrong liquors diſpenſed with ; ſo that the ſtomach may not, by diſtention, preſs upon the heart, and excite it to increaſed action, and that the body be not heated and ſtimulated by the quantity or quality of the food and drink. Great flatulence, or other occaſional ſymptoms, muſt be palliated by appropriate medicines.

It ought not to be omitted, that in the commencement of the diſeaſe ſome phyſicians have recommended evacuations, eſpecially by bleeding, with a view to remove the fulneſs of the veſſels, and therefore to diminiſh the mechanical momentum of the blood in the heart, as well as its ſtimulus to that irritable organ. This doctrine is, however, ſomewhat queſtionable. It is juſtly remarked by Dr. Ferriar, that the ſymptoms of debility which generally accompany the complaint, even at its commencement, the tendency to deliquium (fainting), the weak flatulent ſtate of the ſtomach and bowels, the dropſical ſymptoms, owing to a delay in the return of the blood, and the languid feelings of the patient, ſeem to point out a *careful* exhibition of tonics, as the moſt probable means of arreſting the progreſs of the diſorder. Analogy corroborates this ſuggeſtion ; for in other partial congeſtions, and in palſies, tonics, and even direct ſtimulants, are given with advantage, to recover the tone of the dilated or ruptured veſſels. (Ferriar, loc. cit. p. 168.)

CARDIOIDE, in *Geometry*, a curve ſo called by Caſtilliani. It is thus formed ; let the diameter A B (*Plate* III. *Geometry*, *fig.* 48.) of the circle A M B A, revolve about the point A, and on A B produced let B *a*, M N, A D, M N, &c. be always equal to A B ; then will the point *a* deſcribe a curve, which from its figure reſembling a heart, is called *cardioide*.

From the conſtruction it appears, that A N = B A + A M, and that N M A N is always double of the diameter A B, and is biſected by the circle in M.

This curve is algebraical ; if A B $= a$, $a$ E $= x$, E N $= y$, its equation will be,

$$\begin{aligned} y^4 - 6ay^3 + 12x^2y^2 - 6ax^2y + x^4 \\ + 12a^2y^2 - 8a^3y + 3a^2x^2 = 0 \end{aligned}$$

For the method of drawing tangents, and other properties of this curve, ſee Phil. Tranſ. N° 461. ſect. 8. See alſo Mem. Acad. Scienc. 1705, where M. Carré firſt propoſed this curve.

CARDIOSPERMUM, in *Botany*, (καρδια, *heart*, σπερμα, *ſeed*, from a heart-ſhaped ſpot or ſcar on the ſeed). Linn. gen. 498. Schreb. 680. Willd. 789. Gært. 497. Juſſ. 146. Vent. 3. 126. (*Corindum*, Tourn. La Marck Encyc. *Veſicaria*, Riv. 4. 144.) Claſs and order, *octandria trigynia*. Nat. ord. *trilobatæ*, Linn. *Sapindi*, Juſſ. *Saponaceæ*, Vent.

Gen. Ch. *Cal.* perianth four-leafed ; leaves obtuſe, concave ; the alternate interior ones larger than the others. *Cor.* petals four, obtuſe, alternate with the leaves of the calyx, equal in ſize to the two larger ones. *Nectary* four petal-ſhaped leaflets, coloured, incloſing the germ, ſhorter than the proper petals, and attached to them ; two of them callous at the tip, hooked at the ſide, forming an upright lip ; the others with equal ſides forming a cloſed lip. *Stam.* filaments eight, awl-ſhaped, nearly as long as the nectary, united below ; anthers ſmall. *Piſt.* germ three-ſided ; ſtyles three, ſhort ; ſtigmas ſimple. *Pericarp.* capſule roundiſh, three-lobed, inflated, three-celled, opening at the tip. *Seeds* globular, marked at the baſe with a heart-ſhaped ſcar. Gærtner and La Marck conſider the fruit as conſiſting of three connate, one-celled, valveleſs capſules, united at the axis ſo as to take the appearance of a three-lobed capſule.

Eſſ. Ch. Calyx four-leafed. Petals four ; nectary four-leafed, unequal. Capſule three-lobed, or rather three connate capſules inflated.

Sp. 1. C. *halicacabum*, Linn. Sp. Pl. Lam. Ill. Pl. 317. Gært. Pl. 79. (*Halicacabum*, Rumph. Amb. 6. p. 60. tab. 24. fig. 2. *Piſum veſicarium*, Bauh. pin. 743. Sloane Hiſt. 1. p. 238.) " Stem and petioles ſmooth ; leaflets with gaſhed teeth, ſmooth." Willd. *Root* annual. *Stems* three or four feet long, ſlender, branched, ſtriated, twining. *Leaves* alternate, twice ternate, ſometimes ſlightly pubeſcent. *Flowers* ſmall, white ; common peduncles axillary, ſolitary, thread-ſhaped, furniſhed above the middle with two ſimple, oppoſite tendrils, and ſupporting ſeveral flowers near their extremity on ſhort partial peduncles. *Fruit* ſhort, greeniſh, almoſt ſmooth. A native of the Eaſt and Weſt Indies ; cultivated in England by Gerard in 1594. It flowers here in July. 2. C. *hirſutum*, Willd. " Stem and petioles hairy ; leaflets toothed, ſmooth." *Root* annual. *Stem* four feet high or more, climbing, deeply furrowed, thick ſet with hairs. *Leaves* alternate, petioled, twice ternate ; leaflets egg-ſhaped, acuminate, two inches and a half long, half an inch broad, ſimply and coarſely toothed, ſmooth on both ſides, veined ; axils of the veins pubeſcent beneath ; common petiole almoſt three inches long, furrowed, hairy ; partial petiole an inch or half an inch long, ſemicylindrical, not often beſet with hairs. *Flowers* ſimilar to thoſe of the preceding ſpecies, but larger ; peduncles half a foot long, furrowed, ſmooth. A native of Guinea. 3. C. *corindum*, Linn. Sp. Pl. “ Leaves downy underneath.” Similar to C. *halicacabum*. *Root* annual. *Peduncles* ſupporting ten or eleven flowers among the tendrils, remaining, after the fructification is paſt, rigid. *Capſules* narrower, downy. A native of Braſil. 4. C. *grandiflorum*, Willd. Swartz. Prod. 64. Flor. Ind. Occid. 2. p. 698. “ Leaves pubeſcent ; capſules acuminate, very large.” *Root* perennial. *Leaves* more acuminate than thoſe of C. *corindum*, and not inclining to heart-ſhaped at the baſe. *Flowers* and *fruit* three or four times as large. A native of Jamaica.

CARDISPERMUM. See Calendula *hybrida*.

CARDISSA, in *Conchology*, the name given by Rumpfius to the Linnæan *Cardium cardiſſa*.

CARDITIS, in *Medicine*, the noſological term for inflammation of the heart.

If we conſider the nature and importance of the function of the heart, and the connection of the circulation, of which it is the ſource, with the nervous ſyſtem, the ſtate of temperature, and every other function of the body, we ſhould be led to expect, *à priori*, that the ſymptoms accompanying an inflammation of that organ, would be ſufficiently obvious, and eſſentially different from thoſe, which deſignate an inflammation of any other of the viſcera of the thorax. This, however, is very far from being the caſe. The ſymptoms which attend inflammation of the heart, are fever, pain in the ſituation of the heart, palpitations, an irregular pulſe, cough, difficulty of breathing, and often ſyncope. (Baillie Morb. Anat. p. 42.) It is obvious that the ſymptoms here enumerated are merely the common ſymptoms of peripneumony, or pleuriſy, with the addition of palpitation, irregularity of pulſe, and ſyncope, or fainting. But it is obſerved by Senac, that theſe ſymptoms are extremely uncertain ; and with regard to palpitation, although its preſence may lead us to ſuſpect that the heart is affected, yet it is probably an hypothetical opinion, ſince in that inflammation, which ariſes from wounds of the heart, palpitation does not occur. (Traité du Cœur, tom. ii. chap. 7.) With reſpect to the other two ſymptoms it muſt be remarked, that the preſence of an irregular pulſe, and the occurrence of ſyncope, together with the ſymptoms of pneumonia (or inflammation of the lungs), can only lead to a probable ſuſpicion of an affection of the heart ; ſince they are by no means conſtant attendants on carditis ; and the former very frequently attends other caſes of pneumonia. (Wilſon on Febrile Diſeaſes, vol. iv.) Upon the ſame grounds Dr. Cullen accords with the obſervations of Vogel, that “ the ſymptoms of carditis are nearly the ſame with thoſe of peripneumony, but in general more ſevere ;” and adds, that he has ſeen the *pericardium*, or membranous covering of the heart, inflamed, when no other ſymptoms, but thoſe of peripneumony, had occurred. (Synopſis Noſol. Meth. p. 107. note.) Inflammation of the pericardium, however, cannot be diſtinguiſhed in practice from inflammation of the ſubſtance of the heart. (Baillie, loc. cit.) In fact, inflammation ſeldom occurs in any part of the contents of the thorax, without ſpreading to thoſe in contact with it, as from the pleura to the lungs, from the heart to the pericardium and pleura, &c. Hence the diagnoſis muſt be obviouſly impoſſible in many caſes, where in reality more than one organ is inflamed.

Were we in poſſeſſion, however, of any certain means of diſtinguiſhing carditis from inflammation of the other thoracic viſcera, in a practical point of view it would be of little uſe, ſince the method of *cure* muſt be the ſame, whether the diſeaſe be ſeated in the lungs, pleura, heart, or pericardium. General blood-letting, where the pulſe is hard and ſtrong ; bliſters to the region of the heart ; gentle laxatives of calomel or neutral ſalts ; diaphoretics ; and diluents ; will be the principal expedients : every thing being at the ſame time avoided which can increaſe the local or general irritation.

The ſame *cauſes* muſt be conſidered as giving riſe to carditis, which produce the other modifications of thoracic inflammation ; and the ſame circumſtances will direct us in forming our *prognoſis*, and in adopting particular varieties of treatment. See Peripneumony.

It would appear from diſſections, that there is often a ſlow or chronic inflammation ſubſiſting in the heart, which does not betray itſelf by any peculiar ſymptom. For abſceſſes in the ſubſtance of the ventricles, and ulcers on the external ſurface, have been occaſionally found after death, when no ſymptoms of inflammation had previouſly exiſted. (Morgagni Epiſt. xxv. art. 17. Bonet, tom. i. p. 849, &c.)

CARDITO, in *Geography*, a town of Naples, in the province of Calabria ultra, 8 miles E.S.E. of Reggio.

CARDIUM, in *Conchology*, a Linnæan genus of bivalves, the ſhell of which is nearly equilateral, equivalve, and in moſt ſpecies, convex, longitudinally ribbed, ſtriated, or grooved, with a dentated margin : hinge with two teeth near the beak, and a larger, remote, lateral tooth on each ſide in both valves, and which, when the ſhell is cloſed, lock into each other. Animal inhabitant of the ſhell a *tethys*, having two ſmall pores on the left ſide of the body.

Costatum. A large ſpecies deſcribed by Linnæus that inhabits the African Ocean : the ſhell is gibbous and equivalve with raiſed, carinated, concave, membranaceous ribs. Muſ. Lud. Ulr.—*Concha exotica*, Argenville, *Kaman* Adanſon.—Length three inches ; breadth three inches and a half ; general colour whitiſh, with ſometimes broad brown grooves or ſtripes. Called by Engliſh collectors the *Pipe-ridged cockle*.

Cardissa. Shell heart-ſhaped ; valves compreſſed and carinated with teeth ; beaks approximate. Linn.—*Cardiſſa* of Rumpfius, and *Cor veneris* of Argenville.

Smaller than the preceding, the length being only two inches and a half, and the breadth two inches. The ribs are placed obliquely, and there is a conſpicuous heartſhaped depreſſion before the beaks ; the general colour is whitiſh, ſometimes ſpotted with ſanguineous. Individuals of this ſpecies according to Gmelin are occaſionally found concave on one ſide. It inhabits the Indian Ocean.

Roseum. Shell heart-ſhaped ; anterior part furrowed with lines, poſterior ſtriæ rather broader, and forming by their conjunction a cordated figure ; one part convex, the other concave. Argenville, &c.—This inhabits the Nicobar iſlands, and reſembles the former ; ſhell whitiſh varied with roſe-colour.

Retusum. Shell heart-ſhaped ; valves ſtriated, crenulated, and ſlightly carinated, with lunate cordiform gape behind the beaks.—This ſhell, which is two inches long, and nearly the ſame in breadth, is of a milky-white colour, thick, with the anterior part concave, and poſterior convex ; margin with plaited teeth. Inhabits India, Arabia, and Egypt. Born, &c.

Hemicardium. Shell heart-ſhaped, ſomewhat quadrilateral ; valves carinated ; beaks diſtant. Linn.

This is deſcribed as an inhabitant of the Indian Ocean ; it reſembles Cardium Cardiſſa ; and is of an ochraceous colour, a few of the ribs are glabrous, the reſt nodulous with intermediate grooves wrinkled and marked with excavated dots ; ſhell within ſnowy-white.

Lineatum. Shell heart-ſhaped, carinated, anterior part obliquely truncated, thin, very ſmooth, ſnowy with golden coloured ſtriæ; margin denticulated. Kaemm. lab. Rudolſt.—Shell above an inch long; its native place unknown.

Medium. Shell ſomewhat heart-ſhaped, and ſlightly angulated; valves angulated, ſmooth, and ſulcated. Linn. &c.

Inhabits American Seas. This reſembles *Cardium Hemicardium*; the ſhell is whitiſh, and generally ſpotted with cheſnut or brown; ribs numerous; hinge with a ſingle primary tooth.

Aculeatum. Shell ſomewhat heart-ſhaped, with prominent ribs grooved down the middle and beſet with large hollow aculeations, and ſub-petalous ſpines towards the circumference. Inhabits the Mediterranean and European ſeas. This is a large ſpecies of a browniſh colour, or whitiſh variegated with brown bands. Found on the Britiſh coaſts. Donov. Brit. Shells, &c.

Echinatum. Shell ſomewhat heart-ſhaped, ſulcated, with ſpinous carinated ribs. Linn. &c.—Inhabits European ſeas.

Rather reſembles the laſt in figure, but is ſmaller, and paler in colour; whitiſh, variegated with brown. Found on the Britiſh coaſts. Donov. &c

Ciliare. Shell ſomewhat heart-ſhaped, with triangular elevated ribs beſet along the edges with thin ſpines, Gmel. &c. A native of the African and European coaſts; whitiſh with about eighteen ribs.

Ciliatum. Shell ſomewhat heart-ſhaped, with elevated ſub-triangular ciliated ribs. Inhabits the North Seas. O. Fabr. &c.

This reſembles *Cardium ciliare*, from which it differs, among other particulars, in having about twice the number of ribs: colour cinereous, or greyiſh-white.

Tuberculatum. Shell ſomewhat heart-ſhaped, with obtuſe, knotty, tranſverſely ſtriated grooves. Linn. Inhabits the Mediterranean ſea, and is variouſly coloured and marked; ſometimes white, or whitiſh with brown bands; ſometimes brown with darker bands; ribs from twenty to twenty-three in number, convex, with a few nodoſities.

Isocardia. Shell heart-ſhaped, with arched imbricated ſcales along the furrows. Linn.

An American ſpecies about two inches and a half in length, and two inches and a quarter broad; colour cinereous-white, with a few red ſpots or clouds; ſhell within white, and purple in the middle, and a ſingle primary tooth in each valve at the hinge.

Fragum. Shell ſomewhat heart-ſhaped, and ſlightly angulated with elevated lunules down the grooves. Linn. *Fragum album* of Rumpf.

Inhabits India. Colour white, with yellow, or ſulphur lunules; within ſnowy; ribs flattiſh. Perhaps a ſmall variety of the following ſpecies.

Unedo. Shell ſomewhat heart-ſhaped, with lunate coloured grooves. Linn.

This inhabits India, and reſembles *Cardium fragum*, but is twice as large, and has fewer red ſcales on the grooves; lips of the anterior edge incumbent.

Muricatum. Shell ſomewhat heart-ſhaped, furrowed, and muricated at the ſides. Linn.

A native of the American ſeas; colour cinereous, white or yellowiſh, mixed or ſpotted with bay; margin ſerrated; hinge with two red ſtripes within.

Magnum. Shell oblong, with angular grooves ſerrated at the ſide. Linn.

A ſuppoſed variety of this ſpecies is called the baſket cockle by Martyn. Univ. Conch. Cardium magnum inhabits India, and America: the ſhell is ſerrated on the margin with twenty or thirty grooves, and tranſverſely wrinkled. Colour variable, yellowiſh, ochraceous with duſky ſpots or tawny, and cinereous with blackiſh ſpots; within w:

Flavum. Shell ſomewhat ovate, ſulcated, anterior margin ſcabrous, poſterior one toothed. Linn

A native of India. Back and poſterior end generally yellow, and ſometimes ſpotted, the reſt white; ribs about twenty-ſeven in number, of a convex form, with the firſt five or ſix armed with ſharp ſpines; twelve or thirteen poſterior ones with flat tubercles, the intermediate ones ſmooth.

Lævigatum. Shell obovate, with obſolete longitudinal ſtriæ. Linn.

This kind inhabits the American, Atlantic, and European ſeas. Length about two inches and breadth nearly the ſame: colours various, generally brown or teſtaceous, with darker clouds and ſpots, and ſometimes bands.

Serratum. Shell obovate, ſmooth, with obſolete ſtriæ, ſerrated at the interior margin. Linn.

A native of the Mediterranean and Indian ſeas; ſhell ſmaller and leſs convex than *Cardium lævigatum*; of a yellow colour, with the beaks regular.

Edule. Shell antiquated, with about twenty-eight flattiſh ribs tranſverſely ſtriated with obſolete recurved imbrications.

This is our common cockle, a ſpecies found in the greateſt plenty buried in the ſands on all the arid ſhores of Europe. The animal inhabiting this ſhell has a peculiar flavour, and is eſteemed as a wholeſome and palatable food; the ſpecies varies in ſize and colour, they occur of a large ſize on ſome of the Scottiſh ſhores. Donov. Brit. Shells.

Islandicum. Shell ſulcated, with about thirty-ſix ſmooth triangular ribs. Chemn.

Inhabits the North Seas, eſpecially near the coaſts of Iceland and Greenland; in its general aſpect it reſembles our common cockle, cardium edule, but the grooves are deeper and more numerous, and there are no ſtriæ except the outer margin; colour blackiſh, ſometimes banded.

Groenlandicum. Shell glabrous, thin, mouſe colour, with angulated ferruginous lines; margin glabrous with obſolete longitudinal lines. Chemn.

Same habitat as the former, about two inches and three quarters long, and three inches and a half broad; ſometimes banded with brown.

Rusticum. Shell with twenty remote grooves, the intermediate ſpaces rugged. Inhabits European ſeas. Gmel. &c.

Obſ. The ſpecific name ruſticum has been aſſigned to more than one or two different ſpecies of this genus; the C. *ruſticum* of ſome Engliſh writers is probably only a variety of C. *edule*. Vide Donov. Brit. Shells. C. *ruſticum* of Chemn. may be diſtinct, but that is doubtful.

Glaucum. Shell ſubantiquated, anterior part glaucous: poſterior part with twenty grooves imbricated upwards; beaks violet. Poiret.—Inhabits the ſhores of Barbary. A ſmall ſpecies.

Pectinatum. Shell ſomewhat heart-ſhaped, and pectinated. Linn.—Found in the Mediterranean ſea. General colour white, with the cavity under the beaks yellow; valves marked with diſtant ſtriæ that are rough upwards; margins of the ſhells prominent.

Virgineum. Shell triangular, rounded, equilateral, with tranſverſe membranaceous recurved wrinkles; hinges blue. Gmel. &c. Inhabits the Mediterranean. A variety is found in the Indian and American ſeas.

Strilaterum. Shell triangular, gibbous, and ſtriated. Gmel. Inhabits the Caſpian Sea. An indiſtinct ſpecies.

Auricula. Shell heart-ſhaped, and ſlightly rhombiform with twenty-four ribs on each ſide; the grooves very finely crenulated; beaks diſtant.

Deſcribed by Forſkal as a native of the Arabian ſeas; ſhell white and pellucid, two inches and a quarter long, and one inch and three quarters broad; margin of the back revolute and toothed.

Triste. Shell ovate and ſmooth; margins both of the anterior and poſterior ſlope ſtriated. Linn.

Native place unknown. Shell ſmooth, cinereous, and radiated with white; beaks reflected.

Monstrosum. Shell gibbous, one ſide impreſſed and ochraceous, the other convex heart-ſhaped, and whitiſh ſpotted with yellow; valves with dentated ridges. Chemn. —This is a very rare ſpecies; inhabits the Nicobar iſlands.

Lima. Shell gibbous with aculeated ribs, the anterior ones with recurved membranaceous tubercles crenated at the ſides; the intermediate grooves granulated. Chemn. Inhabits the Nicobar iſlands. This ſhell is ochraceous, with the anterior margin fleſh-coloured, and the beaks reddiſh. A ſuppoſed variety of this ſpecies is deſcribed by Schroet, in which the ribs are more rounded, and inſtead of being aculeated or prickly are only granulated.

Ringens. Shell rotundate, ventricoſe, and white, with deep teeth at the margin, the anterior ones roſy. Liſter, &c. Inhabits the African and Mediterranean ſeas.

Aeolicum. Shell thick, with longitudinal anterior ſtriæ, and tranſverſe ſtriæ behind. Chemn. &c.—A native of Guinea, and the Antilles iſlands. Obſ. This ſhell is very convex, and is varied with white and reddiſh.

Oblongum. Shell yellowiſh, oblong, turgid, and coſtated; anterior part glabrous, and cordiform with a crenated margin. Chemn.—Inhabits the Mediterranean. Length three inches, breadth two inches and a half; ribs about thirty. Much allied to the following ſpecies.

Crassum. Shell ſomewhat fuſcous, rather oblong, thick, antiquated, with a very deeply dentated margin. Schroet, &c.—Reſembles *Cardium oblongum*, but is much larger, rather broader, thicker, and has about twenty-three flattiſh ribs. Alſo inhabits the Mediterranean, and is found in the North Seas.

Papyraceum. Shell pellucid, cinereous, with thin longitudinal ſtriæ. Chemn.—This kind inhabits India; the ſhell is very brittle, within white, with purpliſh ſpots.

Latum. Shell broad with unequal ſides; ribs rather flat and ſpinulous. Chemn. &c.

Length two inches, breadth half an inch more; colour variable, being in ſome individuals white on the crown, yellowiſh in the middle, and edged with yellow; in others the crown is brown, and the reſt of the ſhell banded with fuſcous; inſide white. Inhabits Tranquebar and Nicobar Iſlands.

Maculatum. Shell ſpotted, with crowded undulated wrinkles; ribs broad; grooves very narrow, within pale roſy. Liſt.—Found in the bay of Campechy. This ſhell is nearly three inches long, its breadth rather more, being three inches and three quarters.

Flexuosum. Shell rotundate, fuſcous with flexuous ribs, and rugoſe furrows.

Deſcribed by Liſter; length one inch and three quarters, and about the ſame in breadth. Native place unknown.

Gaditanum. Shell rounded, yellowiſh-white, varied with red, green, and brown, and marked with decuſſated ſtriæ. Bonan. &c. Found near Cadiz. Gmelin conceives this may be an *arca*.

Brasiliense. Shell rounded; ribs broad, flat, and very minutely crenated. Frequent on the Braſilian ſhores. Bonan. &c.

Amboinense. Shell rather oblong, white with blackiſh ſpots: the ribs very convex.—Inhabits the Amboina ſhores. Bonan. &c.—Obſ. This ſhell is about an inch and three quarters in length, with about twelve ribs.

Squamosum. Shell heart-ſhaped, equilateral, tawny white, and purpliſh within; ribs with imbricated ſcales. Gualt.—Reſembles *Cardium fragum*, but wants the teeth at the anterior margin. Native place unknown.

Rubiginosum. Shell reddiſh, with unequal ſides, and convex ribs tranſverſely ſtriated. Gualt. Native place unknown.

Virescens. Shell inequilateral, oblong, with very fine ribs doubled above. Gualt. Native place unknown.

Fasciatum. Shell rounded, whitiſh, with a brown band; ribs acute. Knorr. Native place unknown.

Cancellatum. Shell reddiſh, thin, rounded, with decuſſating ſtriæ. Gualt. Small. Native place unknown.

Albidum. Shell inequilateral, ribbed, whitiſh, and purple within.

Obſ. There are a few other of the larger ſpecies of Cardium deſcribed by conchological writers which we conſider as ambiguous. Theſe, with ſeveral of the more minute, and microſcopic kinds, are purpoſely omitted in the above enumeration of ſpecies, as we are inclined to believe the inſertion of ſuch would rather tend to perplex than inform the general reader.

CARDONA, in *Geography*, a town of Spain, in Catalonia, ſeated on an eminence near the river Cardonero, with a ſtrong caſtle, and the title of a duchy. In its vicinity are an inexhauſtible mountain of ſalt of various colours, which, when waſhed, becomes white; and alſo vineyards, which produce excellent wine, and lofty pine-trees. N. lat. 41° 42′. E. long. 1° 26′.

CARDONERO, a river of Spain, which runs into the Llobregat, at Manxes, in the province of Catalonia.

CARDOON, in *Botany*. See Cynara *Cardunculus*.

CARDS, *playing*, are little pieces of fine thin paſte-board, of an oblong figure and of ſeveral ſizes, but with us commonly $3\frac{1}{2}$ inches long, and $2\frac{1}{2}$ broad; on which are printed divers points and figures; a certain number or aſſemblage of which ſerve for the performance of various games: as baſſet, ombre, picquet, whiſt, &c. A full pack conſiſts of fifty-two cards.

A pack is always wrapped up in a piece of paper, on which are printed the name, ſign, dwelling-place, &c. of the maker; with the label of the ſtamp-office of England, ſignifying that the ſtamp-duty has been paid.

Among ſharpers, divers ſorts of falſe or fraudulent cards have been contrived; as marked cards, breef cards, corner-bend, middle-bend, &c.

*Marked cards*, are thoſe where the aces, kings, queens, and knaves, are marked on the corners of the backs with ſpots of different number and order, either with clear water, or water tinged with pale Indian Ink, that thoſe in the ſecret may diſtinguiſh them. Aces are marked with ſingle ſpots on two corners oppoſite diagonally; kings with two ſpots at the ſame corners; knaves with the ſame number tranſverſed, &c.

*Breef cards*, are thoſe which are either longer or broader than the reſt; chiefly uſed at whiſt and picquet.

The broad cards are uſually for kings, queens, knaves, and aces; the long for the reſt. Their deſign is to direct the cutting, to enable him in the ſecret to cut the cards diſadvantageouſly to his adverſary, and draw the perſon unacquainted with the fraud, to cut them favourably for the ſharper. As the pack is placed either endways or ſideways to him that is to cut, the long or broad cards naturally lead him to cut to them. Breef cards are ſometimes made thus by the manufacturer; but in defect of theſe, ſharpers pare all but the breefs with a razor or pen-knife.

*Corner bend*, denotes four cards turned down finely at one corner, to ſerve as a ſignal to cut by.

*Middle-bend*, or *Kingſton-bridge*, is where the tricks are bent two different ways, which cauſes an opening or arch in the middle, to direct likewiſe the cutting.

The inventor of cards is not known, nor even the age when they firſt appeared; but by the matter they were always made of, viz. leaves of paper, they ſhould ſeem to be much poſterior to the time of Charlemagne. The hon. Daines Barrington, Mr. Bowle, and Mr. Gough, in their three eſſays on the "Antiquity of Card-playing," (Archæologia, vol. viii.) ſeem to agree that the Spaniards have the beſt pretenſions to be conſidered as the original inventors of this amuſement. Others have traced their invention to about the year 1390, for the purpoſe of diverting Charles VI. then king of France, who was fallen into a melancholy diſpoſition, and aſcribe it to Jaquemin Gringonneur, a painter in Paris. Accordingly in the accounts of the treaſurer of that prince the following article occurs; "Paid fifty ſix ſhillings of Paris to Jaquemin Gringonneur the painter, for three packs of cards, gilded with gold, and painted with diverſe colours and diverſe devices, to be carried to the king for his amuſement." From this article it appears, that playing cards were originally very different in their appearance and their price from what they are at preſent. They were gilded, and the figures were painted or illuminated, which required no little ſkill and genius, as well as labour: and the price of each pack was no leſs than 18s. 8d. of Paris, a very conſiderable ſum in thoſe times. This laſt circumſtance is one reaſon that playing cards were little known and uſed for ſeveral years after they were invented. By the four ſuits or colours, the inventor might deſign to repreſent the four ſtates or claſſes of men in the kingdom. The *cœurs* or hearts denote the *gens de chœur*, choir-men or eccleſiaſtics. The nobility or prime military part of the kingdom, is repreſented by the ends or points of lances or pikes, which through ignorance of the meaning of the figure, we have called ſpades. By diamonds are deſigned the order of citizens, merchants, and tradeſmen. The trefoil leaf, or clover graſs, corruptly called clubs, alludes to the huſbandmen and peaſants. The four kings are David, Alexander, Cæſar, and Charles; repreſenting the four celebrated monarchies of the Jews, Greeks, Romans, and Franks under Charlemagne. The queens repreſent Argine (for Regina, queen by deſcent), Eſther, Judith, and Pallas; which are typical of birth, piety, fortitude, and wiſdom. The knaves denote the ſervants to the knights: others apprehend that the knights themſelves were denoted by theſe cards, becauſe Hogier and Lahire, two names of the French cards, were famous knights at the time when they were ſuppoſed to be invented.

The firſt certain notice of their having been known in England occurs in a record in the time of Edward IV. On an application of the card-makers of London to parliament, A.D. 1463, an act was made againſt the importation of playing-cards, 3 Edw. IV. c. 4. From this ſtatute it appears, that both card-playing and card-making were known and practiſed in England before this period, or about 50 years after the æra of their ſuppoſed invention. Mr. Gough obſerves *(ubi ſupra)*, that the uſe of cards among the Chineſe is evident, not only from a Chineſe painting which repreſents their ladies playing at a game with ſomething much thicker in ſubſtance than cards, yet ſhaped and numbered like them, but alſo from a pack of Chineſe cards in his poſſeſſion, made of the ſame materials as the European However, the devices on theſe cards are very different from thoſe known in this part of the world. Although card-playing was introduced at comparatively a late period in England, and the progreſs of it was at firſt ſlow, it hath ſince become ſufficiently rapid and extenſive, to the coſt of many unfortunate gameſters, and the loſs of many others, who ſpend too much of their time in that infatuating amuſement. Lord Lyttelton in his Perſian letters (apud Miſcellaneous works, vol. i. p. 143), admirably rallies thoſe who indulge their propenſity for this kind of diverſion to exceſs, and who riſk ſums of money which it is not convenient for them to loſe; or, in other words, who pervert it to the purpoſe of gaming. Selim repreſents himſelf as viſiting at a houſe in London, where he ſaw a number of tables in a room, round which were placed ſeveral ſets of men and women. They ſeemed (ſays he) wonderfully intent upon ſome *bits of painted paper*, which they held in their hands: I imagined at firſt that they were performing ſome magical ceremony, and that the figures I ſaw traced on the bits of paper were a myſtical taliſman or charm. What more confirmed me in this belief was the grimaces and diſtortions of their countenances, much like thoſe of our magicians in the act of conjuring; but inquiring of the gentleman who introduced me, I was told they were at *play*, and that *this* was the favourite diverſion of both ſexes. But, as he proceeds, I ſee no ſigns of mirth among them: if they are merry, why do not they laugh, or ſing, or jump about? If I may judge of their hearts by their looks, half of theſe *revellers* are ready to hang themſelves! that may be, ſaid my friend; for very likely they are loſing more than they are worth. How! ſaid I, do you call that *play?* Yes, replied he, they never are thoroughly pleaſed unleſs their whole fortunes are at ſtake. Thoſe *cards* you ſee them hold, are to decide whether he who is now a *man* of *quality* ſhall be a *beggar;* or another, who is now a *beggar*, and has but juſt enough to furniſh out one night's play, ſhall be a *man of quality*, &c. &c.

The method of making playing cards ſeems to have given the firſt hint to the invention of printing; as appears from the firſt ſpecimens of printing at Haerlem, and thoſe in the Bodleian library.

Cards, *making of.* The cutting of the moulds, or blocks, for theſe cards, is preciſely the ſame as that uſed for the firſt books; and a ſheet of wet or moiſt paper is laid on the form or block, which is firſt lightly bruſhed over with an ink, made of lamp-black mixed with ſtarch and water; and then rubbed off with a round liſt, in the hand. The court-cards, they colour by help of ſeveral patterns, called "ſtaneſiles;" conſiſting of papers cut through with a penknife: within the apertures, or inciſions of which, the ſeveral colours, as red, &c. are ſeverally applied (for at the firſt printing, the card has only a mere outline.) Theſe patterns are painted with oil colours, to keep them from wearing out by the bruſhes: being laid on the paſte-board, they ſlide a bruſh full of colour looſe over the pattern; which leaving the colour within the apertures, forms the face or figure of the card.

This, very probably, was the way of the firſt printing at Haerlem; as might have been diſcovered long ago, if it had been conſidered, that the great letters in our old manuſcripts of nine hundred years ago, are apparently done by the illuminers, after the method of card-making.

By 43 G. III. c. 60, a duty is impoſed of 2l. 8s. on every dozen packs of playing cards imported: and for every pack of cards, made in Great Britain, the ſtamp duties by ſeveral acts amount to 2s. 6d., and for every pair of dice, 17s. 6d.

Places of making them are to be entered under a penalty of 50l., and forfeiture of the cards, dice, materials, and utenſils. Makers of cards ſhall ſend to the commiſſioners of the ſtamp-office a ſufficient quantity of paper in order to have as many aces of ſpades impreſſed upon them as he ſhall deſire; and a device, denoting the ſaid ace of ſpades, ſhall be ſtamped on every pack uſed in Great Britain or intended for exportation, which device ſhall diſtinguiſh cards deſigned for home conſumption from thoſe intended for foreign conſumption:—and wrappers incloſing cards for uſe in Great Britain ſhall have the name of the maker or any other particular word printed on them, according to the direction of the commiſſioners, who ſhall denote one of the 6d. duties charged on cards in Great Britain on each of ſuch wrappers. Officers ſhall enter houſes or places where cards and dice are made or ſold, or ſuſpected to be made, or any public gaming-houſe, to ſearch and examine whether ſuch cards are ſtamped; and the owner or occupier refuſing ſuch entrance or ſearch ſhall forfeit 10l. No materials for cards or dice ſhall be removed till they are finiſhed, on pain of double duty; nor ſhall any cards or dice be removed, till they are duly marked or ſealed, on pain of forfeiting the ſame and treble value. Entry ſhall be made once in 28 days on oath, under a penalty of 20l., and the duties ſhall be cleared off once in every ſix weeks, on pain of double duty. Selling or uſing unſtamped cards or dice, incurs a forfeiture for every pack and for every one of ſuch dice of 10l. with full coſts. Altering the ſtamps ſubjects to a forfeiture of 20l. and the ſale or purchaſe of ſuch ſtamp incurs the ſame forfeiture. A perſon who takes off the ſtamp of any playing cards, or outſide paper of any parcel or pack of cards, for the purpoſe of uſing it again, ſhall be guilty of felony, and tranſported for any time not exceeding ſeven years. The ſelling of waſte cards, not previouſly rendered unfit for uſe in playing, incurs a forfeiture of 20l.; and any perſon who ſells any cards, as ſecond-hand cards, in packs or parcels, the wrapper of which has been broke open, unleſs every card be rendered unfit for play, forfeits 5l. for every ſuch pack. If any perſon counterfeit the ſtamp on cards or dice, or the wrapper, or knowingly ſells the ſame with a counterfeit ſtamp, or fraudulently uſes any of the ſtamps provided by the commiſſioners, he ſhall be guilty of felony without benefit of clergy. No cards or dice ſhall be exported or expoſed to ſale without being ſtamped, until after the expiration of ten days after notice to the ſtamp-office by the maker of the quantity to be exported, and of the place to which they are intended to be conveyed, nor until a proper certificate be delivered to the cuſtom-houſe officer at ſuch poſt or place in Great Britain. Cards or dice may be removed by the maker without payment of the duties, provided the ſame be ſtamped for exportation, and a bond be given for exporting them within the time, and landing them at the port therein mentioned. Cards for exportation ſhall before packing be marked as the commiſſioners direct; and perſons uſing or ſelling ſuch cards, marked for exportation, in Great Britain, ſhall forfeit 20l. for every ſuch pack: and any perſon relanding any parcel of cards, entered and ſhipped for exportation, ſhall forfeit 50l.; and if any perſon concerned ſhall inform againſt an accomplice, he ſhall be admitted as evidence, and be indemnified.

CARDS, in *Manufacture*. See CARD.

CARDUCHI, in *Ancient Geography*, a ſtout warlike people of Aſia, who were deſcended from the ancient Scythians, and divided into a great number of tribes. According to Strabo they were at a period ſubſequent to that of the famous retreat of Xenophon better known by the name of Parthians; a nation which became ſuch a terror to the Romans. M. De Liſle, in the explication of his map of Xenophon's retreat, alleges ſeveral arguments to prove, that they were the ſame with the preſent Curds, and that their country was the ſame which the Romans called Carduena, a large and mountainous territory on the eaſt of the Tigris, and the moderns Curdiſtan; though it is probable, that the preſent tract which goes by that name is of much greater extent than that which the Carduchi then poſſeſſed, who only occupied the mountainous parts of it. Before the period of the retreat of the Greeks, they had defeated a Perſian army of 120,000 men, none of which ever returned, the roads being impaſſable. Upon the approach of Xenophon's army they betook themſelves to flight with their wives and children, and gave the Greeks a favourable opportunity for ſupplying themſelves with plenty of proviſions. Xenophon was much haraſſed by looſe bands of theſe people, who diſcharged upon him and his rear-guard which he conducted, vollies of darts and ſtones. The Carduchi were much ſuperior to the Greeks in the uſe and ſtrength of their bows. We are told (Diod. Sic. lib. xiv. Xenophon, Anabaſ. lib. iv.) that they were of ſuch prodigious length, that they bent them with their feet; the arrows were in proportion, ſo well tempered and keen, and darted with ſuch violence, that no ſhield could reſiſt them; ſo that, by being able to throw them at ſuch a diſtance, they kept themſelves out of the reach of their enemies.

CARDUEL, or CARTHUEL, in *Geography*, a name given to the eaſtern part of Perſian Georgia; the capital of which is Teflis.

CARDUELIS, in *Ornithology*, the name under which the common gold-finch is deſcribed by Geſner, Aldrovandus and others. See FRINGILLA *Carduelis*, Linn. CARDUELIS *Americana* of Briſſ. is the American gold-finch of Engliſh writers; FRINGILLA *triſtis*, Gmel.

CARDUENA, in *Ancient Geography*. See CARDUCHI.

CARDUNCELLUS, in *Botany*, Lob. ic. 2. p. 20. See CARTHAMUS *Carduncellus*.

CARDUNCULUS. See CYNARA.

CARDUUS, (a name given by the ancient Latin writers to ſeveral kinds of prickly plants, and particularly to the teaſel, (dipſacus fullonum) formerly uſed in *carding* wool, as it ſtill is in dreſſing cloth. The word is ſaid to be derived from caro, (Gr. *κειρω*,) a technical verb denoting the operation of cleanſing wool from its impurities.) Thiſtle, Linn. gen. 925. Schreb. 1254. Willd. 1433. Juſſ. 173. Vent. vol. ii. p. 499. Gært. 932. Chardon, La Marck Encyc. Claſs and order, *ſyngeneſia polygamia æqualis*. Nat. ord. *capitatæ*, Linn. *Cinarocephalæ*, Juſſ.

Gen. Ch. *Cal. common*, ſwelling out in the middle, imbricated; ſcales numerous, lanceolate; terminated by a ſimple ſpine; in ſome ſpecies ſtrong, in others weak. *Cor.* Florets all furniſhed with ſtamens and a piſtil, uniform, tubular, funnel-ſhaped, nearly equal, reflected; tube very ſlender; border erect, five-cleft; ſegments linear, equal, one more deeply ſerrated than the reſt. *Stam.* Filaments five, capillary, ſhort; anthers united, forming a hollow five-toothed cylinder. *Piſt.* Germ egg-ſhaped; ſtyle thread-ſhaped, longer than the ſtamens; ſtigma ſimple, awl-ſhaped, naked, emarginate. *Peric.* none; except the permanent, ſomewhat converging, common calyx. *Seeds* ſolitary, inverſely egg-ſhaped, a little four-cornered; down ſeſſile, long, deciduous. *Recep.* hairy.

Eſſ. Ch. *Cal.* ſwelling out in the middle, imbricated; ſcales terminating in a ſimple ſpine. *Receptacle* hairy. *Down* deciduous.

This genus, like moſt of the others in the claſs ſyngeneſia, is differently characterized by different authors. Some have divided the Linnæan genus into two: *carduus* including only thoſe ſpecies which have a capillary down, and *cirſium* containing thoſe whoſe down is feathery. Willdenow has united the latter with *cnicus*, and makes the eſſential difference between *carduus* and *cnicus* to depend entirely on the nature of the down. La Marck, on the other hand, has aboliſhed the *cnicus* of Linnæus, which, he ſays, has a character too vague to be admitted; and has diſtributed its ſpecies between carduus and carthamus, obſerving, that ſome ſpecies of carduus in the Species plantarum, approach rather too near the character of carthamus. After a careful conſideration of the ſubject, we are inclined to adopt his arrangement; and have conſtructed accordingly the generic and eſſential characters of carduus given above, adding from Gærtner, "down deciduous," which has the ſanction of Dr. Smith; though we are not without apprehenſion, that this character may not be found in all the preſent acknowledged ſpecies.

Species. * *Leaves decurrent.*
